THE appeal of *Pickup v. The Dental Board*, which was dismissed by a court consisting of the Lord Chief Justice, Mr. Justice Avory, and Mr. Justice Shearman on May 10th, has an interest for the medical as well as the dental profession. Again and again, in cases before the General Medical Council, it has been argued on behalf of the respondent that the Council has no power to erase his name on account of conviction for a misdemeanour when such misdemeanour is not of the class which is triable on indictment, but the Council has consistently overruled such objections, being advised that the word "misdemeanour" in the Medical Act is used in the widest sense. The case recently decided was an appeal against the order of the General Medical Council, on the recommendation of the Dental Board, that the name of one James Pickup should be erased from the *Dentists Register* on the ground that he had been convicted of misdemeanours within the meaning of Section 13 of the *Dentists Act*, 1878. The case was reported when it came before the General Medical Council in the *Supplement* to our issue of December 10th, 1927 (p. 227). In

\* See *British Medical Journal*, April 23th, p. 721.

dismissing the appeal the Lord Chief Justice said that the contention of the appellant that the expression "misdemeanour" in Section 13 meant misdemeanour triable on indictment could not be supported. This was clear from the words of the section. There was a proviso to the section stating that when the offences were of a trivial nature they might not be held to disqualify a person from practising dentistry. Thus it seemed to be contemplated that the misdemeanours in the section were not confined to indictable misdemeanours, but would include others, even those which, by their trivial nature, made the application of the proviso proper. The other justices concurred.

In his address from the chair of the Dental Board on May 8th, before this case had been decided, the Right Hon. Sir Francis Dyke Acland referred to this impending judgement, and said that he trusted a judgement would be obtained as to the offences which might properly be termed misdemeanours and which would be of service to the General Medical Council as well as to the Board.

#### FORGERY OF A DEATH CERTIFICATE.

At the Old Bailey, on May 18th, Charles Forbes, who was alleged to have posed as a registered medical practitioner in the West Central district of London for seven years, pleaded guilty to forging and uttering a death certificate, and was sentenced to nine months' imprisonment, without hard labour. It was stated that the certificate was issued in respect of an old woman who had been under the care of the accused. The defence alleged that Forbes had qualified as a medical practitioner, but that his name had been removed from the Medical Register thirty years ago after he had been convicted of fraud. According to a statement made in the course of the earlier police court proceedings, Forbes described himself to the registrar of births and deaths as a graduate of Aberdeen University; the registrar, after supplying the accused with a book of certificates, came into possession of a letter which aroused his suspicion and communicated with the General Medical Council.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE Currency and Bank Notes Bill was read a third time in the House of Commons on May 22nd, on which day the House of Lords read the Equal Franchise Bill a second time after a division. The report and the third reading of the National Health Insurance Bill were set down for May 23rd. On May 24th the House of Commons rose for the Whitsun recess till June 5th, when the Finance Bill will come up for second reading.

The Parliamentary Medical Committee met at the House of Commons on May 22nd and considered questions to be raised on the report stage of the National Health Insurance Bill. It was reported that on the third reading of that bill Mr. Chamberlain might indicate that he hoped at a future date to propose the provision of medical and midwife's attendance in childbirth as a statutory benefit under the national health insurance scheme.

#### Ministry of Health Estimates.

In the House of Commons, on May 15th, a vote to complete the sum of £20,774,000 for the Ministry of Health was considered. Mr. CHAMBERLAIN explained that the Estimate showed an increase of nearly £1,000,000 over last year. Practically half of the gross estimate of £21,700,000 was needed for the housing branch of the Ministry. With regard to slums, the most urgent feature was overcrowding. He saw, however, ground for hope in the fact that although only 14,000 houses were affected in the schemes submitted for slum clearance during the war, every year over 500,000 houses were built. The estimates showed a small increase under each of the headings in connexion with which the Ministry of Health distributed Departmental grants to local authorities for certain services. There were four of these services: treatment of tuberculous disease, maternity and child welfare work, venereal disease, and welfare of the blind. Generally it might be said that the increases were due to the normal development of the services. But this did not exhaust the functions of the Ministry of Health. He had always regarded the Ministry as a sort of general headquarters staff, whose duty it was to collect information regarding the fight against disease and make it available to all concerned in the campaign. A great deal of research had been carried on in regard to cancer, which was perhaps the largest single cause of mortality. That research had dealt with the causes and treatment of cancer both in this country and abroad. They had not yet been able to put their fingers upon any fact or series of facts which would allow them to say that they had solved the problem of cancer—very far from it—but all the time they were encroaching upon the field of the unknown; all the time they were advancing their knowledge. The Ministry of Health had mapped out a sort of scientific survey of what could be done to-day in the effective treatment of cancer, and they had followed that up with a careful

and exhaustive inquiry into a large number of cases of cancer. They had also done something to bring into prominence certain methods of treatment which they had ascertained, from information derived from this country and abroad, had proved particularly effective in the treatment of cancer. These were methods of radiology—the use of radium itself and so-called x-ray therapy. These methods were costly, and were not easily adopted by all authorities, but they believed that by proper organization more effective use could be made of the equipment which they actually possessed. They were keeping in the closest touch with a great number of other agencies—the British Empire Cancer Campaign, the public health authorities throughout the country, and the local cancer committees working in some of the great provincial centres. While they could not say that they were even in sight of a cure or of a method of prevention of cancer, nevertheless they were on the right path, and one day—no one could say when—they might actually turn the corner and find themselves in the presence of the goal which they sought.

Encephalitis lethargica was a disease in regard to which central action was particularly necessary if they were to make progress, because this disease was fortunately not sufficiently common yet for any hospitals or any private practitioners to have seen very many cases of it. During the past two years there had been about 1,500 cases a year in this country. The Ministry had instituted an exhaustive inquiry into about 3,000 cases of sleepy sickness. It had been carried out by Dr. Parsons, one of the officers of the Ministry of Health, and the results of the inquiry showed that only about 25 per cent. of the cases recovered; about 35 per cent. died, and the remaining 40 per cent. were more or less disabled mentally or physically. The valuable part of this inquiry was that for the first time they knew what were the proportions of the persons attacked by this disease who recovered, died, or were permanently injured. They knew the different forms of injury which sufferers from encephalitis lethargica might sustain; they knew how those things proceeded, and they had got for the first time some inkling of what were the best ways of treating the disease. The inquiry came very opportunely after the passing of the Mental Deficiency Act, because in the light of the inquiry they might hope that that Act might be put to more effective use. The inquiry disclosed a considerable variety of cases, and it must be understood that the treatment which might be effective and desirable for one case might be quite wrong for another. The Mental Deficiency Act would enable them to classify cases and treat them in the best manner. He thought that the popular impression that encephalitis lethargica was tending to decrease was correct, but, of course, sufficient remained to make it a very serious problem, because the effects of the disease were frequently permanent, and a person once affected remained a charge upon the community perhaps for the rest of his life.

There were really two distinct groups of diseases which came under the heading of rheumatism—acute rheumatic fever, which so often attacked children and which was frequently associated with heart disease, and chronic rheumatism of the joints and muscles, which frequently disabled industrial workers. Last year approved societies spent on sickness benefit and medical benefit for rheumatic insured persons £5,000,000, and in the same year 5,250,000 weeks' work were lost owing to the incidence of rheumatism among insured persons. They calculated that rheumatism accounted for one-sixth of the whole industrial invalidity of the country. With regard to rheumatism he was told that the treatment which afforded the best hope was one of prolonged rest in institutions, and the Ministry of Health during the past two or three years had tried to encourage the provision of hospital accommodation set apart specially for this purpose. To-day, for the first time, we had actually got from 400 to 500 beds specially earmarked for the treatment of acute rheumatism. As regarded chronic rheumatism, the first thing required was advice, because the causes of this rheumatism were many and various, and it might, and very frequently did, spring from some local centre of infection. It might be the teeth that were wrong, or the tonsils, or the intestinal tract. In the absence of advice, people accepted rheumatism as though it were a sort of act of God, which could not be prevented, and for which nothing could be done. Yet, under the advice of the specialist, it might be traced to some quite easily removable cause, and the suffering might be almost instantaneously relieved. A great deal was being done for that. In the case of the children there was the school dental service, which employed something like 600 dentists, and was treating about 1,000,000 children a year. In the case of the elder insured persons there was the dental benefit, to which approved societies were now devoting some £3,000,000 a year, with a result which he hoped would show itself in a lessened demand upon the funds in the future from rheumatism, and the consequent incapacity to work. At present approved societies were paying about £250,000 a year to two hospitals for the treatment of their patients, and another £200,000 a year was being devoted to convalescent homes in connexion with which, in some cases, there was now being developed spa treatment. But they felt that something more than this was required, and that there were forms of treatment, especially those connected with radiant heat and light, which had shown very promising results experimentally, and which the Ministry desired to see extended for the benefit of a larger part of the population. The Red Cross Society was now trying to organize the setting up of an experimental clinic of this kind in London, and as soon as that was ready he proposed, by regulation, to authorize approved societies to make a contribution to that clinic and to obtain treatment for their members there. The committee would realize that the full development of a preventive and curative system in connexion with rheumatism must mean the expenditure of very large sums of money. It might be that in the present financial state of the country it was not possible to carry on that development as rapidly as we should wish, but we were at last beginning to realize the nature of the disease with which we had

to cope, and the extent to which it was crippling our people, and, as that knowledge became more widespread, he thought that we should see a willingness to devote to the improvement of those conditions whatever money might be found necessary.

The Ministry of Health had now been established for nine years, and as far as one could measure the progress of the public health by the general vital statistics the record of the Ministry was not unsatisfactory. The general death rate in those years had gone down from 14 per 1,000 to 12.3, and the infant mortality rate had dropped from 89 to 70 per 1,000. But there was one figure which showed no improvement—it concerned a very vital subject. That was the maternal mortality. It was a terrible thing to think that 100 mothers, one died in childbirth. That was not really the full measure of the injury that was being done. One must not only remember what happened to the family when the mother was taken away, but one must think of those other mothers who might not die, but who emerged from their confinement permanently injured in their health and unable really to fulfil the full duties of motherhood. He felt that the time had come when a great new effort ought to be made to bring down those figures of maternal mortality and to improve the health of these mothers. There were many things we did not know yet about the causes of maternal mortality, but we did know something. We knew that these figures persisted steadily throughout the country, but, nevertheless, they were not universal. There were places where we could find much lower figures. They would be found in those cases where there was the most careful antenatal and post-natal supervision, and where the people themselves had the greatest opportunities of learning what was necessary for them to preserve their health and the lives of their infants. The Ministry of Health was taking up this question very seriously. He was now endeavouring to institute a new inquiry into the causes of maternal mortality. He was trying to enlist in that service the general practitioners throughout the country, as well as the local authorities; and the British Medical Association had assured him that it was deeply interested in the question, and would use all its influence to get its members to give every assistance possible to his inquiry. Under this scheme a local medical officer of health would make inquiry into every case of maternal mortality which occurred, wherever it might be, throughout the country. They would make this inquiry on a plan which would be laid down by a committee at the Ministry of Health on the lines of the Cancer Committee. Their returns would come in quarterly to that committee, the information would be classified, and the committee would draw what conclusions it was possible to draw from the information obtained. All that information would then go back again to the local authorities, and would be made known to those responsible for the conduct of the infant welfare centres and the maternity hospitals. He was also setting up a committee to inquire into the whole position of midwives—into their status, training, and remuneration. After all, the success or failure of any efforts made to improve the conditions of childbirth in the country must largely depend on the midwives, on whom a great responsibility rested. Midwifery was a hard and arduous profession; it was not a well-paid profession; and if we were to get the right class of women to enter that profession we must make the conditions such that this class of people would be attracted. If we could indicate with any confidence to the people of this country what were the precautions necessary to take if we were to remove this menace from our midst, he could not believe that the national conscience would allow the lives of the mothers to be sacrificed merely for the sake of a few extra thousands of pounds.

In the ensuing debate Dr. FREMANTLE said that while he admitted that there was still a great lack of houses, he thought the accounts given were exaggerated. Taking the census of 1911 as a basis—and it was the only sure one—our housing shortage to-day was only about 40,000 houses. He did not think that the position was getting worse in regard to overcrowding; speaking generally, it would be found that the position was very slowly improving.

Dr. WATTS congratulated the Minister of Health, and remarked that ever since Mr. Neville Chamberlain had been at the head of the Ministry he had shown not only a knowledge of administration, but of medicine, and a mastery of scientific fact quite unusual in a layman. He felt that the Ministry was becoming referred to another department, perhaps the Home Office. The medical service in connexion with the Factories Act might be removed from the Home Office to the Ministry of Health. Thus they would co-ordinate, under the Ministry of Health, the entire health services of the country. With regard to tuberculosis, we were still spending some millions of pounds a year on the upkeep of sanatoriums. However useful they might be from a preventive point of view, or for the segregation of tuberculous people, they were, from a curative point of view, of little use. Some portion of the money available might usefully be devoted to investigating other methods which, in the opinion of several medical members, offered a much better prospect of cure.

Mr. SCARLETON asked if Dr. Watts found, from actual evidence, that sanatorium work was not producing results commensurate with the expenditure on it.

Dr. WATTS: From the curative point of view, most decidedly. The sanatorium method, he said, could only show 14 per cent. of cures, which was very low, whereas other methods showed 70 or 80 per cent. of cures. He also wished to call attention to the serious increase of small-pox, and the question of vaccination. For some time past a great number of people had not only not had their children vaccinated, but had not taken the trouble to make the necessary declaration of a conscientious objection. The result was that the law in this respect was practically a dead letter. He hoped that something would be done in this matter, because those of them who knew small-pox, and were acquainted

with its history, realized that previous epidemics had always been preceded by sporadic outbreaks of a mild character, which had suddenly burst forth into a virulent epidemic, which had carried away thousands of people and crippled thousands of others. That was a very real danger which he anticipated if vaccination was not going to be more general in this country. This was the only country in the civilized world where vaccination was not carried out. He had had an example of the way in which other countries dealt with this question when, last autumn, he went to Brazil with a delegation from the Commercial Committee of the House of Commons. They were freed from all troubles in regard to passport and customs examinations, but the Brazilian Ambassador said to them: "There is one obligation from which I cannot free you, and that is the obligation to be vaccinated." All the delegation had to be revaccinated before leaving this country.

Dr. VERNON DAVIES said that the greater part of the debate had been taken up with housing and slums, but very little had been said on the question of health, yet that was fundamentally the duty of the Minister of Health. The Minister spoke about cancer and the progress that had been made in its treatment, referring particularly to radium treatment. He seemed to create the impression that the Ministry of Health was anxious to help the radiologists to deal with cancer, and that it was very hopeful as to the results. He (Dr. Davies) wished to impress upon the House and upon the country that the only safe treatment for cancer was early and complete operation. In late and inoperable cases radium treatment might prolong the life of the patient, or perhaps give him a little more ease. Whatever they did, they should not get into their heads the idea that radium would cure cancer. It could not do it at the present time. It was only a help, and he was afraid that the rather hopeful tone of the Minister of Health might create a wrong impression in the country, and thus prevent some of these poor people from seeking medical advice in the early stages when something could be done.

He was glad that the Minister dealt with rheumatism. This question had come to the fore lately, and all who read the address of the Chief Medical Officer of the Ministry of Health were very much impressed. It proved that the Minister had in his department a full knowledge of rheumatism and of its bad economic, social, and physical effect. The Minister said that there were 400 to 500 beds in the country earmarked for the treatment of rheumatism in children. That number was almost ludicrous when they knew that with young children the huge majority of those who got rheumatic fever or acute rheumatism developed heart disease, and that it was essential that they should be given absolute rest for a long time. It seemed pitiable that, in the whole of this great country, with the thousands of free beds in our Poor Law institutions, something could not be done to see that these poor children could be taken to hospital and kept there until they were fit for a more or less useful life.

The question of maternity always roused the sympathy of the House, and he was certain that the Minister was fully alive to the importance of this subject, but he was not sure that they were using the material they had at hand to the best advantage. They heard of a shortage of midwives, but it must be borne in mind that the midwife's life was a very difficult one—a very hard life and poorly paid. Yet he had known of many cases where midwives were thoroughly trained and yet could not get a sufficient amount of work for the reason that the better-class patients now went to nursing homes and the poorer-class patients went to Poor Law hospitals. He knew more than one midwife who was seriously concerned as to how she was going to carry on her livelihood on account of these claims at both ends taking away the patients which she previously had. That was a point which the Minister would have to bear in mind, especially if he was going to increase the number of midwives. Another question which he wished to bring before the House was that of milk. A great campaign was going on in the country by which everybody was advised to drink more milk, and everything was being done to show people the advantages of milk, and, of course, the Ministry were doing all in their power in conjunction with the Ministry of Agriculture to impress these plans on the public. They had got to know recently that milk was a perfect food, that it was rich in vitamins, and that it was the only suitable nourishment for young children or suckling children. It was also a very useful food for adults, and they were doing all they could to see that this country produced good pure milk at a cheap price. At present there was a great deal of milk adulteration going on. The adulteration was of a lower standard in the towns than in the counties, and the only conclusion he could come to was that in the counties the administration of the Sale of Food and Drugs Act was usually carried out by the police authorities, who acted by a rule-of-thumb method. They administered the Act rather from the point of view of saving the purchaser's pocket and seeing that he got full value than from the point of view of health. That was a grave mistake. The function of the Ministry of Health should be not to save the pockets of the people, but to look after their health. When one considered that, with the records in their department of the enormous adulteration that had gone on, they had apparently done nothing, that fact must be weighed in the balance against the many acknowledged excellencies of the department. He suggested that the administration of the Sale of Food and Drugs Act in regard to foodstuffs, and milk in particular, should be taken out of the hands of the police and put in the hands of the local health authority.

Sir BASIL PETO said attempted abortion was a material contribution to maternal mortality. Septic peritonitis almost always supervened upon attempted abortion. He suspected that the prevalence of venereal disease was also closely associated with it. He asked that the restrictive regulations for welfare centres and ante-natal centres should be relaxed and that medical officers in charge should have unfettered discretion to give or withhold

information on birth control. He was told that, though there was some diminution in syphilis, gonorrhoea was on the increase. Yet the official system of the Ministry refused to allow the civil population access to preventive measures from which the army and navy admirable results had followed. Could the Minister now declare, as he had done in 1925, that the prevalence of venereal disease was diminishing?

Mr. PETHICK LAWRENCE asked what the Government had done to classify the maternal death rate. Had they figures to show what deaths resulted from carelessness of doctor, midwife, or nurse; from poverty or malnutrition, or from the fact that some women ought never to have had a child at all? When it was certain that, if a woman had a child, that child would be diseased or defective, or if that woman's life was going to be imperilled by bringing a child into the world, doctors in clinics supported out of public money should have the right to give information. Women in all classes were determined to have this information, and if it could not be given them scientifically by appointed officers of the State, they would get it in ways less correct, and possibly more injurious. Undesirable forms of information, when disseminated among women, were difficult to eradicate, and some doctors now had a grave problem in trying to alter what had been passed from one to another among the poorer women of the country.

Mr. BLUNDELL dissented, contending there was no evidence to show that the failure of maternal mortality to diminish was due to the failure of ante-natal clinics to give information about birth control.

Mr. SCRYMGEUR asked whether there was to be an outcome from the report of the Royal Commission on Lunacy. The practice of relegating people suffering from mental depression to an institution where there were others more seriously affected was deleterious. Parliament was dealing with venereal disease in too timid a fashion.

Sir KINGSLEY WOOD said that until the House of Commons came to a contrary decision the Minister of Health and the department intended to maintain the present formula that maternity and infant welfare centres should only deal with expectant or nursing mothers, that it was not the function of an ante-natal centre to give information on birth control, and that exceptional cases where avoidance of pregnancy seemed desirable on medical grounds should be referred to a private practitioner or to a hospital. It would be a great pity if over 2,000 centres attended by about a third of the women who gave birth to children were involved in this controversy. Sir Kingsley spent most of his speech in answering the criticisms of the Government's housing policy. He also dealt with allegations concerning the death of a child at Chester-le-Street which had been alleged to be hastened by malnutrition. He contended that inquiry had not confirmed this allegation.

The vote for the Ministry of Health was carried by 203 to 99.

#### *Treatment of Mentally Deficient Prisoners.*

The House of Commons, on May 21st, considered, in Committee of Supply, the vote for £275,969 for the expenses of prisons in England and Wales. Mr. RHYNS DAVIES moved a reduction of the vote by £100, and asked how many cases of encephalitis lethargica there were at the moment in the gaols. One of the biggest tragedies in this country was that there was no appropriate institution to which to send cases of that kind.

Sir VIVIAN HENDERSON (Under Secretary to the Home Office), replying to various questions raised in the debate, said that every effort would be made to improve the accommodation at the prisons, and to improve the recreation and workshop facilities. With regard to sleepy sickness, it was stated, in the medical part of the 1926 report of the Prison Commissioners, that during the period under review no case of the onset of encephalitis lethargica occurred during detention in prison or in any Borstal institution. It showed that the whole question was being carefully watched by the medical officers concerned. Where any question of mental defect was considered by the medical officer of the prison to exist, steps were now being taken to transfer those persons to a prison which was specially adapted or where special treatment was given. Birmingham was one of those prisons. The Prison Commissioners were following up this question and trying to eliminate prisoners apparently suffering from any mental defect. Such prisoners were dealt with very much more leniently and received a different type of treatment from that given to the ordinary prisoner. Whether they were dealt with in the same way as if they were sent to a mental institution he could not say offhand. He had not been able, personally, to look into the matter, but it had not been overlooked, and was being dealt with to a certain extent. The Mental Deficiency Act, passed last year, also covered a certain amount of the recommendations of the Young Offenders Committee in regard to this question. In the prisons every step was taken to see that where clothing was handed over from one man to another it was thoroughly and properly disinfected, and that in no case was it in a condition where it could give any disease to anybody. In the last two years there had been a very considerable improvement in the diet, particularly in variety. He did not honestly think that there was any reasonable ground for complaint on that score. At a later stage in the debate Sir V. Henderson said that special steps were now taken, where a man was committed to prison and the prison doctor thought he was of a low state of mental efficiency without actually being certifiable, to transfer that man to a special prison. That was a new departure which was being carefully watched, and, if successful, would be further developed.

The amendment was negatived and the debate adjourned.

*Recommendations of the Royal Commission on Lunacy.*—Answering, on May 17th, questions by Mr. Snell and Sir Nicholas Grattan-Joyce, Mr. CHAMBERLAIN said he appreciated that early legislation was desirable in pursuance of some, if not all, of the recommendations of the Royal Commission on Lunacy and Mental Disorders, but owing to the other commitments of the Government he could not say when it would be practicable to introduce a bill.

*Certification of Mentally Deranged Persons.*—On May 21st Sir KINGSLEY WOOD replied to Sir F. Hall, who asked if his attention had been called to cases which had occurred from time to time in recent years in which mentally deranged people who would ordinarily be under restraint had, owing to the liberty allowed them, committed suicide; whether he was aware that in some of these cases doctors and magistrates had refused to sign certificates owing to their fear of possible legal proceedings, and whether he would appoint a departmental committee to consider and advise whether any amendment of the law relating to the certification of lunatics was desirable. Sir Kingsley said that the answer to the first part of the question was in the affirmative. The Minister of Health saw no necessity for the appointment of a departmental committee to consider the matter, as the Royal Commission on Lunacy reported upon difficulties of this kind and made a recommendation for an amendment of the law.

*Report of the Voluntary Hospitals Commission.*—Replying, on May 17th, to a question by Mr. Lunn, Mr. CHAMBERLAIN said the final report of the Voluntary Hospitals Commission, of which Lord Onslow was chairman, was in the printer's hands, and the work of the Commission would be concluded with the issue of the report. Excluding contributions towards specific grant-aided services, the total Exchequer grants in aid of the general expenses of voluntary hospitals since 1918 amounted to £500,000; and the distribution of this sum by the Commission was completed on March 31st, 1924. There had always been cases of voluntary hospitals in financial difficulties, but a great improvement had happened in the last few years, and in the absence of a further contribution from the Exchequer it would be no use to keep the Commission in being. Colonel ACLAND-TROTTE suggested that the voluntary hospitals should be relieved of all rates. No answer was returned.

*Motor Accidents and the Voluntary Hospitals.*—Sir KINGSLEY WOOD told Mr. Lunn, on May 22nd, that the Minister of Health hoped that the report of the Voluntary Hospitals Commission would be issued this month. The Minister of Health must receive and consider the report of the Commission before deciding whether, in view of the great increase in cases caused by motor accidents which had to be dealt with by the hospitals, he would call a conference between representatives of the voluntary hospitals, insurance companies, and other organizations concerned, for the purpose of drafting a scheme to cover the expenses of the treatment of cases caused by motor accidents. Mr. Lunn asked if Sir Kingsley knew that last year there were more than 100,000 motor accidents, which cost voluntary hospitals more than £500,000, and that thousands of people awaited treatment for whom these hospitals were created, but who could not be treated because of motor cases which were going into the hospitals and paying nothing for their treatment. Sir Kingsley WOOD said that those facts might be true, and when the Ministry of Health received the final report of the Commission he hoped it would be able to give this matter further consideration.

*Fees of Doctors Summoned to Urgent Cases.*—Answering a question on May 16th, Sir KINGSLEY WOOD said he had not seen the evidence given at an inquest at Shoreditch on Ernest March, of Rochford, Essex, at which an allegation had been made that a doctor, summoned to attend this man, refused to do so because his fee could not be paid by the person summoning him. It appeared from a press report that the coroner was not satisfied that the facts were as alleged, and the Minister of Health did not consider it desirable to introduce legislation making it compulsory for doctors to attend urgent cases and for their fees to be paid from public funds. Sir Kingsley added that he did not think the Shoreditch case was anything more than an exceptional one.

*Pensions Hospitals.*—On May 22nd Lieut.-Colonel G. F. STANLEY told Mr. Robinson that the staff employed in area war pension offices outside London numbered 1,471, and that employed in Ministry hospitals and clinics in the provinces, in Scotland, and Northern Ireland numbered 1,647. Arrangements had had to be made to vacate two hospitals—Craigleith, Edinburgh, and Castle Leazes, Newcastle-on-Tyne, which were too large for their requirements—provision being made for the patients in substituted institutions of the Ministry at Edenhall and Dunston Hill. Apart from these cases, it was not possible to say what local offices, clinics, or hospitals it might be found necessary to close during the present financial year.

*Prevalence of Venereal Disease.*—Sir KINGSLEY WOOD, replying to Sir B. Peto on May 22nd, said that syphilis and gonorrhoea were not compulsorily notifiable, and the only information available as to their prevalence in the civilian population was that obtained from the treatment centres provided by local authorities. The returns received from these centres showed that since 1920 there had been a considerable reduction in the number of persons treated at the centres, although the figures for the last two years showed a small increase over those for 1925, which was probably due to recent improvements in the facilities provided at some of the centres and to continued propaganda as to the dangers of these diseases. He was not aware that the present policy in dealing with these diseases involved any denial of access to preventives through chemists. The restrictions imposed by the Venereal Diseases Act,

1917, applied only to written or printed notices or instructions in regard to the use of preventives. Sir B. Peto asked whether the diminution and recent increase, to which Sir Kingsley had referred, applied equally to both diseases or only to one. Sir KINGSLEY said that there was a slight difference between the two diseases, but he did not think the increase was a very large one.

**Small-pox.**—On May 21st Sir KINGSLEY WOOD, replying to Mr. Groves, who asked the Minister of Health whether, seeing that when small-pox contacts were isolated the inspector filled in a printed form giving information on various points, including when the contact was last vaccinated, and that such forms came into the possession of the medical officer of health, he would say why they were not used for the compilation of information as to the vaccinal condition of small-pox contacts who subsequently developed small-pox, said that the Minister was advised that it was not the usual practice to isolate small-pox contacts. Mr. Groves's question therefore did not arise.

**Expenditure on Cancer Research.**—Mr. CHAMBERLAIN, replying to a question on May 22nd, said that the provisional number of deaths registered during 1927 as caused by cancer was 51,079. The expenditure borne on the vote of his department during the five years ending March 31st last which was directly assignable to cancer research was £8,843. In addition the Exchequer grant administered by the Medical Research Council was applied to the promotion of research into this and other diseases.

**Compensation for Insanitary Premises.**—On May 22nd Mr. CHAMBERLAIN told Sir R. Gower that compensation on the basis of site value applied only to premises which were included in a scheme as confirmed on account of the sanitary condition of the houses, or because those premises were dangerous or prejudicial to health. He was of opinion that the provisions of Section 46 of the Housing Act, 1925, were, in some respects, unsatisfactory, and he had under consideration proposals for amending them.

**Water Supply of Schools.**—Answering Dr. Vernon Davies, on May 17th, Lord EUSTACE PERCY said he was in constant communication with the Minister of Health about schools which had no water supply. Lord Eustace also told Mr. March that he had no particulars showing how many of the fifty-two schools in Herefordshire which were without water in 1925 were still unprovided, nor how many public elementary schools in England and Wales had no sanitary accommodation but privy middens.

#### Notes in Brief.

On March 31st, 1928, there were 5,944 physically defective children on the rolls of special schools in London, compared with 5,347 on March 31st, 1924. In Birmingham the corresponding figures were 1,165 and 1,101.

The Minister of Health is not prepared to postpone the operation of the regulation prohibiting the use of preservatives in cream.

The number of cases of overcrowding and other insanitary defects in workshops notified to local authorities by factory inspectors were 3,334 in 1925, 3,051 in 1926, and 2,775 in 1927. The reports of the medical officers of health showed that twenty-five workshop occupiers were prosecuted for sanitary offences in 1925 and 1926.

## The Services.

### DEATHS IN THE SERVICES.

Major-General Sir Samuel Hickson, K.B.E., C.B., Army Medical Service (ret.), died at Bournemouth on March 22nd, aged 68. He was born on November 12th, 1859, the fourth son of the late Captain R. M. Hickson of Dingle, Kerry, and educated at Trinity College, Dublin, where he graduated B.A., M.B., and B.Ch. in 1884. Entering the R.A.M.C. as surgeon on May 30th, 1885, he became brevet lieutenant-colonel on August 22nd, 1902, lieutenant-colonel substantive on May 30th, 1905, brevet colonel on January 2nd, 1913, and colonel on July 7th, 1914, retiring on December 26th, 1917. He served in the Mashonaland campaign in South Africa in 1896-97, and he was mentioned in dispatches in the *London Gazette* of February 18th, 1898, and received the medal with a clasp; in the South African war in 1899-1901, in operations in the Orange Free State and in Cape Colony, was mentioned in dispatches in the *London Gazette* of July 29th, 1902, and gained the Queen's medal and King's medal, with two clasps to each, and a brevet lieutenant-colonelcy; and in the recent war of 1914-18, when he was thrice mentioned in dispatches, in the *London Gazette* of October 19th, 1914, December 24th, 1917, and December 30th, 1918, and received the C.B. and K.B.E. He was appointed honorary surgeon to the King in 1913, received the C.B. in 1915, and the K.B.E. on January 1st, 1919; also the honorary rank of major-general on May 8th, 1919. He married, in 1903, Elizabeth Constance, widow of R. Fry, and younger daughter of the late Rev. Canon Belsher of Cork.

Dr. George Dougal McReddie died at Greenhithe, Kent, on May 10th, at the great age of 91. After taking the M.R.C.S. and the M.D. Brux. in 1877, he entered the unenvied medical service in India, and served for thirty years in the North-West Provinces, now the United Provinces of Agra and Oudh. As he retired over thirty years ago there can be none left on the active list, and not very many on the retired list, who served with and remembered him.

## Obituary.

### ARTHUR MANKNELL, M.B., B.S.,

Past-President, Yorkshire Branch, British Medical Association.

It was with a distinct feeling of a personal loss that the medical profession in Bradford heard of Dr. Manknell's death, which took place on May 13th. He had been working within a week of the end, and its suddenness increased the profundity of the blow.

Arthur Manknell was born at Leeds in 1866. He received his early education there, and then proceeded to the Yorkshire College, whence he graduated M.B.Lond. in 1891 and B.S. in 1893. He also obtained the M.R.C.S. and L.R.C.P. diplomas in 1891. When the Yorkshire College became the University of Leeds Manknell received the M.B., Ch.B. *ad eundem* of the new institution. After graduating he held the appointments of senior house-surgeon and ophthalmic and nasal house-surgeon at the General Infirmary in Leeds, and then went to Bradford as assistant to the late Dr. David Gyder of that town. On the death of the late Dr. S. C. Hirst of Craisterdyke, near Bradford, Manknell took over the latter's extensive practice, and carried it on with ability and success till his untimely decease. He was an excellent general practitioner, careful, conscientious, and considerate, with the welfare of his patients ever at heart, and was held in high esteem by them. In religion he was a sound Churchman, and took an active part in the affairs of his own parish, wherein he had held office as churchwarden, and also of the diocese, wherein he served on various committees. He took nothing for granted, but worked *de visu*, and thus his utterances were always authoritative.

Among his professional brethren Manknell was held in great and deserved regard. Nothing was too much trouble for him; he worked early and late, often at considerable sacrifice, in promoting the interests of the profession, and his presence was always looked for and desired at meetings. Perfectly definite in utterance, he gave his views on any subject clearly; ambiguity was foreign to him. His advice was much sought after in various matters, being sound, weighty, well matured, and to the point, and he was as a tower of strength to a younger man who had a difficulty to solve. But it is for his great and loyal devotion to medical politics that Manknell will be chiefly remembered. Always an active member of the Bradford Division of the British Medical Association, he was till the day of his death one of its chief pillars. He had been its chairman, and he had also held the office of president of the Yorkshire Branch. He was representative of the Bradford Division from 1912 to 1914, and again from 1921 to 1927. He had also served on a number of central committees and subcommittees of the Association, including the Public Health and the Medico-Political and Parliamentary Committees, and for the past nine years had been a member of the Council. In committee and Council meetings his quiet common sense and close attention to business were highly appreciated by all. Manknell was also one of those instrumental in the success of the Annual Meeting held at Bradford in 1924, on which occasion he held office as president of the Section of Medical Sociology. He took a prominent part in the meetings which preceded the inauguration of the National Health Insurance Act, but when that measure became law Manknell accepted office as chairman of the Local Medical and Panel Committee, and was still chairman at the time of his death. He will be difficult to replace, as the experience he had garnered conducted much to the smooth working of the panel system in Bradford. He had also been president of the Bradford Medico-Chirurgical Society, and served on its council.

The funeral service, which took place at the Bradford Cathedral prior to the interment at Nab Wood cemetery on May 16th, was attended by a large concourse of his medical colleagues, the general public, and the representatives of institutions with which he had been connected. The Bishop of Bradford, in the course of his address, testified very feelingly to the loss which the Church, the medical profession, and the public had sustained. Dr. Manknell is survived by his widow, his son, and his daughter. The gap which he has left among us in Bradford will be hard to fill. *Valde defensus est.*

J. B. D.

Dr. ANDREW GILMOUR, whose death occurred suddenly at Wimbledon, on May 13th, in his fifty-second year, was a native of Edinburgh, and was educated at George Watson's College and the University in that city, graduating M.B., Ch.B. in 1898. He proceeded M.D. in 1902, and in the same year obtained the diploma in public health. In 1912 he was admitted M.R.C.P.Ed. He devoted the greater part of his career to work in the public health service after serving as a medical officer throughout the South African war. He spent some ten years in Paisley, being appointed assistant medical officer for that burgh in 1909, and later school medical officer. On the reorganization of the Scottish educational system in 1919 the county became the administrative unit, for this purpose he was appointed senior school medical officer to the Renfrewshire Education Authority. Soon afterwards he accepted office under the Hindley Urban District Council, where he remained till 1922, when he was appointed medical officer of health for the borough of Wimbledon, holding also the posts of school medical officer, medical superintendent of the isolation hospital, and borough bacteriologist and analyst. During the late war he held a commission in the R.A.M.C., serving in Gallipoli, Salonika, France, and Belgium. He was a Fellow of the Royal Institute of Public Health, and of the Society of Medical Officers of Health, and a member of the British Medical Association. His funeral service was attended by the Mayor and many members of the Corporation of Wimbledon, and of the various civic departments and institutions with which he was associated. Among the mourners was his brother, who is also a medical practitioner. Dr. Gilmour is survived by his widow and a young son. A colleague writes: He was one of the few who, though advancing in age, do not lose any of their enthusiasm for their work. Public health work was his hobby throughout his life, and much of his spare time was occupied in formulating schemes and reports for the improvement of the efficiency of his department. Such keenness often brings with it extremism, but there was no suggestion of this in him, and all his public health judgements were brewed and well thought out. At the borough isolation hospital he did some of his best work, for fevers was a branch of medicine in which he was most interested. He was among the earliest to take up the use of anti-scarlet fever serum, and was keeping careful records of its efficacy. Quite recently he equipped and started working the borough bacteriological laboratory, in which he spent much time and took considerable interest. To the general practitioner he was always ready to give freely his best help and advice, and his loyalty to his colleagues and to his profession as a whole will long be remembered. As a man he was rather sensitive, and for this reason was occasionally misunderstood. But those who had the privilege of being admitted to his friendship found a charming personality and a heart of gold, always kind and ready to help to his utmost those in trouble or difficulty.

Dr. ARTHUR STAYT DUTTON, who died in London on March 25th, had been an invalid for some years before his death, which occurred at the age of 63. He received his medical education at St. Thomas's Hospital, obtaining the diplomas L.R.C.P. and M.R.C.S. in 1892. A considerable part of his professional life was spent in Oxford, although in his later years he resided mainly in London. He contributed to the proceedings of several professional societies, and was a frequent correspondent to medical journals; he was the author of a book, published in 1908, entitled *The National Physique*. He was keenly interested in research work, and even in his last illness maintained his contact with professional affairs. He is survived by his widow.

Dr. THOMAS DRYDEN NICHOLSON died on April 29th, after a short illness, at his residence at Brampton, Cumberland; he had spent the greater part of his professional life in the Shap district in the neighbouring county of Westmorland. He was born at Greystoke Gill in 1864, and obtained his medical education at Edinburgh, graduating M.B., C.M. in 1890. He subsequently commenced practice at Bolton-on-Dearno in Yorkshire, and held the post of honorary

surgeon to the Montague Cottage Hospital, Mexborough. In 1899, however, he removed to Shap, where he carried on a practice covering a very extensive and thinly populated area under arduous conditions for over twenty years, holding during this period a number of public and other medical appointments. About eight years ago he moved to the milder climate of Brampton, where the conditions of medical practice were less exacting. He was appointed honorary surgeon to the Brampton and District War Memorial Cottage Hospital. Dr. Nicholson served on the council of the Border Counties Branch from 1923 to 1926, and on the Executive and Ethical Committee of the English Division of that Branch from 1925 to 1927. He took a keen interest in public affairs, and was for long a prominent member of the North Westmorland Conservative Association. He was a member at one time of the Shap Urban District Council, and in 1912 was appointed a Justice of the Peace for Westmorland. One of his favourite recreations was boxing. He is survived by his widow, two sons, and two daughters.

Dr. REGINALD SPENCER PEARSON, who died suddenly at his residence in Lambeth on May 1st, was a native of Cumberland, where he was born in 1866, being the son of a clergyman. He received his medical education at Owens College, Manchester, obtaining the diplomas M.R.C.S.Eng. and L.R.C.P.Lond. in 1890, and subsequently, in 1898, the D.P.H. After a period of service as medical officer of health to the Wigan rural district, he commenced practice in North London, where he remained for about ten years. For family reasons he then moved to Leighton Buzzard for a time, being medical officer to the Linsdale rural district, and on his return to London he settled down in the Clapham district, where he built up an extensive practice. He served also as medical officer to Spurgeon's Orphanage, to the Church of England Home for Waifs and Strays, and to St. Joseph's Catholic Home, Clapham. He was a Fellow of the Medical Society of London and a member of the British Medical Association, in which he served on the executive committee of the Lambeth and Southwark Division. On the London Panel Committee he represented the insurance practitioners of Lambeth. During the past few years Dr. Pearson took an active interest in municipal affairs, and ten years ago he secured a seat in the borough council of Lambeth, in which he held the office of mayor for a period which ended only last November. He was among the most popular and most conscientious of municipal workers, and devoted himself particularly to public health affairs, being notably active recently in connexion with child welfare. An earnest churchman, he had been for several years one of the churchwardens of Lambeth Parish Church. He was also a keen Freemason, and took a considerable interest in sport. At the funeral service, held at the Lambeth Old Parish Church, there were present many representatives of the borough of Lambeth, of the church, and of the medical profession. Dr. Pearson is survived by his widow, three sons, and a married daughter.

Dr. ELIZABETH PARK YOUNG PATERSON died in a Glasgow nursing home after a brief illness on May 2nd, at the age of 33. She was a native of Clydebank, and received her medical education at the University of Glasgow, graduating M.B., Ch.B. in 1918, and obtaining the D.P.H. in 1925. After a succession of resident posts in Glasgow—in the Royal Infirmary, the Sick Children's Hospital, the Maternity Hospital, and the Eye Infirmary—she held an appointment under the Ayrshire Education Authority, and subsequently spent about two years in ante-natal work in Leeds. She then returned to Clydebank, where she commenced practice, and was appointed medical officer to the old Kilpatrick Parish Council. Two years ago she was appointed an assistant medical officer for maternity and child welfare work on the staff of the Glasgow public health department. She was a member of the British Medical Association. A colleague writes: Dr. Elizabeth Paterson was deeply interested in child welfare work, and brought to it an appreciation of practical difficulties gained by experience in varied branches of practice. She had a kind heart and sympathetic manner, but to this was added a

shrewdness and firmness born of knowledge of human nature. Of the esteem in which she was held by her friends and colleagues it is unnecessary to write. This was well demonstrated by the large attendance at the funeral service held in Radnor Park United Free Church, Clydebank, of which Dr. Paterson was an active member. The profession was well represented, and there were present members of both the medical and nursing staffs of the Glasgow public health department.

Dr. HARRY MORTLOCK WALLER, who died suddenly at Nuneaton on May 17th, in his fifty-seventh year, entered the profession late in life, and received his medical education at St. Bartholomew's Hospital, obtaining the diploma L.M.S.S.A. in 1918. He subsequently held a medical appointment under the Ministry of Munitions, and spent several years in the Far East, where he was at one time medical officer to H.H. the late Rajah of Sarawak and to the Sarawak Government, and served for a period as principal medical officer of that territory. On returning to England he practised in various districts—notably in Cheshire, Carnarvon, Nottingham, and Cardiff—and for the last three years had been resident at Nuneaton. He had served as a medical referee under the Ministry of Pensions, and acted for a period as honorary surgeon to the Griff division of the St. John Ambulance Association. A short time ago he decided to retire, and had just completed the disposal of his practice when he had a seizure which proved fatal. Dr. Waller, who was a member of the British Medical Association, is survived by his widow and two daughters.

## Universities and Colleges.

### UNIVERSITY OF LONDON.

The title of Professor of Experimental Pathology in the University has been conferred on Dr. Archibald Leitch in respect of the post held by him as Director of the Research Institute at the Cancer Hospital, London.

The title of Reader in Pathological Chemistry in the University has been conferred on Dr. C. R. Harington in respect of the post held by him as Lecturer in Pathological Chemistry at University College Hospital Medical School.

Dr. Geoffrey Hadfield has been appointed as from May 1st, 1928, to the University Chair of Pathology, tenable at the London School of Medicine for Women. Since 1919 he has been pathologist, bacteriologist, and clinical pathologist to the Bristol General Hospital.

Dr. Percival Hartley has been appointed as from August 1st, 1929, to the University Chair of Biochemistry, tenable at the London School of Hygiene and Tropical Medicine. Since 1922 he has been on the staff of the National Institute for Medical Research, Hampstead.

Dr. F. D. Turner has been appointed a Governor of the Royal Grammar School, Colchester, and Dr. M. E. Delafield as representative (in respect of University College) at the International Convention of Cancer, to be held in July next.

The Dunn Exhibitions in Anatomy and Physiology for 1928 have been awarded to Mr. J. D. H. Bird of King's College.

Dr. Robert Knox has been recognized as a teacher of radiology at the Cancer Hospital. Probationary recognition has been granted to Mr. G. P. Crowden as a teacher of physiology at University College for a period of two years from March, 1928.

It has been resolved to institute, in accordance with the regulations on University titles, a Readership in Morbid Anatomy and Histology, tenable at the Middlesex Hospital Medical School, and a Readership in Bacteriology, tenable at University College Hospital Medical School.

Dr. W. W. Jameson has been admitted to the Faculty of Science as from January 1st, 1929.

The regulations in the Faculty of Medicine for internal students have been amended by the addition at the end of the first paragraph, under the heading "Second Examination for Medical Degrees, Part II," on page 251 of the Red Book, 1927-28, of the following: "either as an internal or as an external student."

The regulations for the First Examination for Medical Degrees have been amended by the addition of the following paragraph at the end of the section headed "General Biology," on page 245 of the Red Book, 1927-28, and page 218 of the Blue Book, September, 1927:

Candidates will be required to bring to the practical examination note-books containing a record of their previous practical work for inspection by the examiners if desired. These note-books must be notes made by them in the laboratory.

Dr. John Favcett has been elected chairman of the Committee of the Medical Members of the Senate for the remainder of the year 1927-28; Sir John Rose Bradford, P.R.C.P., has been the appointed vice-chairman of University College Committee for the year 1928-29.

### NATIONAL UNIVERSITY OF IRELAND.

The following degrees and diplomas in the Faculty of Medicine were conferred at University College, Dublin, on May 12th:

M.D.—G. T. Irceen, W. H. B. Maganran.  
M.B., B.Ch., B.A.O.—S. J. Savage, G. A. O'Reilly, L. P. Youngsao, P. J. Ald, L. Brennan, Frasn Carroll, W. E. Channing, J. D. Grant, J. A. Henry, M. J. Kovany, W. P. Lapple, J. J. McCarthy, T. S. McDavitt, F. A. McDonald, J. F. S. McLaughlin, M. T. O'Reilly, Maude F. Tenny, M. G. Walsh.  
D.P.H.—M. J. Sheehy, Kato A. Moran, V. L. Coghlan, Hanora Casey, Josephine Conway, W. R. Cusson, Margaret M. Purcell.

### ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The following 25 successful candidates, out of 84 entered, having passed the requisite examinations between January 2nd and 7th, have been admitted Fellows:

Eliso V. Crowe, A. Cumming, F. W. Duthie, P. Garson, B. Gluck, C. D. Gossage, C. Grantham-Hill, G. A. Hardwicko, A. Hobson, L. W. Houghton, C. W. Isaac, J. R. Learmonth, F. I. Lewis, E. O. Lloyd, Beatrice H. Lunn, C. R. McCash, B. L. McFarland, S. McMahon, J. C. Mekie, R. G. Phillips-Turner, F. E. Stagner, S. M. Vassallo, G. I. Wilson, C. L. Walker, J. F. Zohrab.

### Bathgate Memorial Prize.

The Bathgate Memorial Prize, consisting of bronze medal and set of books, has, after a competitive examination in materia medica, been awarded to J. I. Meikle.

### ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, IRELAND.

At the spring examinations, held under the conjoint scheme, the following have passed in the examinations noted:

FINAL QUALIFYING EXAMINATION IN MEDICINE, SURGERY, AND MIDWIFERY.—G. P. A. Condon, P. Daly, E. P. Mahood, T. L. G. Malone, R. J. McCloskey, J. F. Power, P. B. Walsh.  
D.P.H.—F. J. Ryan.  
D.P.M.—G. N. W. Thomas.

### ROYAL COLLEGE OF SURGEONS IN IRELAND.

The following candidates have been approved at the examinations indicated:

PRELIMINARY FELLOWSHIP.—R. L. Forsyth, M. B. Lavery, T. R. Lundy.  
FINAL FELLOWSHIP.—D. V. O'Connor.

## Medical News.

THE Samuel Augustine Courtauld Institute of Biochemistry of the Middlesex Hospital will be opened on Thursday, June 14th, at 3.30 p.m., when Sir Archibald Garrod will deliver an address.

THE Macalister Lecture before the London Clinical Society will be delivered at the London Temperance Hospital, Hampstead Road, N.W.1, on Thursday, June 7th, at 8.45 p.m., by Sir Berkeley Meynham, P.R.C.S., on medicine in art. All medical practitioners are invited to attend with friends. Those intending to be present are asked to notify Mr. H. P. Winsbury White, honorary secretary, 51, Harley Street, W.1.

THE next Chadwick Lecture will be given at the Chelsea Physico Garden at 5 p.m. on Thursday, June 7th, by Professor W. E. Dixon on narcotic plants. Sir William Collins will preside. Admission is free. Further information about Chadwick public lectures may be had from the secretary, Mrs. Aubrey Richardson, at the offices of the Chadwick Trust, 204, Abbey House, Westminster.

AN evening reception will be held at the house of the Royal Society of Medicine (1, Wimpole Street, W.1) on Monday, June 4th. The guests will be received by the President and Lady Berry at 8.30 o'clock, and at 9.15 Mr. C. Leonard Woolley will give an illustrated address on recent excavations at Ur of the Chaldees. Objects of interest will be shown in the library, and there will be music and light refreshments.

At the meeting of the Society for the Study of Inebriety to be held in the rooms of the Medical Society of London (11, Chandos Street, Cavendish Square, London, W.) at 4 p.m. on Tuesday, July 10th, Dr. H. M. Vernon will open a discussion on the scientific control of alcoholism.

THE annual meeting of the Sheffield Branch of the Medical Women's Federation will be held in the Medical Library, The University, Sheffield, on Saturday, June 30th, at 3.30 p.m., when a lecture will be given by Dr. Letitia Fairfield on child guidance, or American methods of dealing with mal-adjusted children. Non-members of the Federation will be cordially welcomed.

THE fifth annual congress of the Incorporated Association of Hospital Officers will be held at the Royal Horticultural Hall, Westminster, on June 1st and 2nd, with Sir Arthur Stanley in the chair. The subjects to be discussed are wireless in the hospitals, including its effect upon patients and the broadcast appeals, and hospitals as centres of education. The annual dinner of the association will be held at the

Hotel Cecil on the evening of June 1st. From May 29th to June 1st, in the Royal Horticultural Hall, there will be a hospitals and institutions exhibition.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on Wednesday, May 30th, Mr. Ogler Ward will give a clinical demonstration in urology at St. Peter's Hospital, at 2 p.m., and that on Thursday, May 31st, at 4.30 p.m., Dr. H. C. Semou will give a clinical demonstration at the Royal Northern Hospital. Special courses will be given in June as follows: at the Children's Clinic and other hospitals a course in diseases of children, June 4th to June 16th; at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, a course in diseases of the chest, and at the Chelsea Hospital for Women a course in gynaecology, both from June 18th to 30th; at the West End Hospital for Nervous Diseases, a course in neurology from June 25th to July 21st; a practitioner's course in medicine, surgery, and the specialties at the London Temperance Hospital from June 18th to 30th, in the late afternoon. It may be recalled that the general course of work continues throughout the year and may be begun at any time. Special arrangements are made for part-time study. Full particulars may be had from the Fellowship of Medicine, 1, Wimpole Street, W.1.

A POST-GRADUATE course in genito-urinary diseases, consisting of weekly lectures on special subjects, will be given in June and July at St. Paul's Hospital, Endell Street, W.C.2, whence details may be obtained. No fee will be charged and the lectures are open to any medical practitioners and students who may care to attend. The first lecture will be given on Thursday, June 7th, at 4.30 p.m., and subsequent lectures at the same hour on either Wednesdays or Thursdays until July 26th.

THE annual meeting of the Society for the Relief of Widows and Orphans of Medical Men was held on May 16th, when the annual report and financial statement were presented and the officers were elected for the ensuing year. The annual report showed that during 1927 four members were elected, three died, and one resigned. The society had a total membership of 303, with invested funds amounting to £139,400. The sum of £4,782 was distributed in grants among the fifty-one members and seven orphans, and on December 31st fifty widows and one orphan were in receipt of grants. A subcommittee has been formed to consider the question of membership of the society with a view to its expansion. Membership is open to any registered medical practitioner who at the time of his election is resident within twenty-one miles of Charing Cross. Should he remove outside the radius he nevertheless remains a member of the society, provided he conforms to the by-laws. Further particulars and application forms for membership can be obtained from the secretary of the society, 11, Chandos Street, Cavendish Square, W.1.

AT the annual meeting of the Infants Hospital, Vincent Square, Westminster, on May 21st, it was announced that a big extension scheme, involving an expenditure of £250,000, is to be undertaken. Ground has been acquired adjoining the present site, and it is hoped to commence reconstruction soon. The scheme provides for more than doubling the number of cots available, for creating a new maternity block, for enlarging and modernizing the surgical section, for greatly increasing the out-patient accommodation, and for making new quarters for the nursing staff. Sir Gower Berry, chairman of the committee of management, who presided, intimated that as a memorial to his wife he proposed to make a gift to the hospital of £50,000, payable over the next seven years, to cover the entire cost of a new maternity block.

THE opening of the extension of the Mildmay Mission Hospital in Austin Street, Bethnal Green, took place on May 19th. Lord Radstock, who presided, recalled the origin of the hospital, saying that more than sixty years ago, when London was visited by a terrible plague of cholera, the Rev. W. Pennecfather and a staff of trained deaconesses set on foot in Bethnal Green a work for the benefit of the suffering. The mission then inaugurated was now known as the Mildmay Mission Hospital. It was unique among hospitals in that it had sent out at least 75 doctors and 120 nurses into the foreign mission field, and 350 women had received at the hospital a measure of practical training to fit them for tending the sick at home or abroad. The extension was then dedicated by the Rev. Colin C. Kerr, rector of Spitalfields, and formally opened by Lady Cooper. The x-ray department, which was the gift of Sir H. Percy Shepherd, was opened by him. Mr. Herbert S. Shipton, chairman of council of the hospital, said that nobody, except himself, knew how very much was owing to Dr. Henry White, the medical superintendent, and Miss Woodhouse, the matron. The sum which it was necessary to raise for this scheme was £22,764, and up to the previous evening the amount received had been £19,051.

THE report of the National Baby Week Council for 1927 records the various measures employed, with considerable success, by this body in the advancement of the ideals for which it stands. Many of its efforts have been duly noted from time to time as they occurred. The number of baby weeks, health and baby weeks, baby competitions, and other local propaganda activities assisted during the year was 564; an experiment in propaganda work in rural districts, conducted by the Cambridgeshire Federation of Women's Institutes, yielded satisfactory results in spite of the difficulties attending such efforts in thinly populated areas. Film displays, the use of which has been considerably extended, have also proved valuable in bringing home to those interested the need for instructed motherhood. The council's 1928 campaign again provides for the celebration of National Baby Week during the first seven days of July, in the course of which the usual programme of conferences and competitions has been arranged. As in former years, while regarding all aspects of maternity and child welfare as important, the council urges that attention should be given especially to three selected problems. These are: (a) immunization as a means of protecting young children against disease; (b) prevention of maternal mortality, with special reference to ante-natal care and to the provision of maternity homes and hospitals; and (c) new developments in maternity and child welfare work.

THE committee appointed by the Royal Medico-Psychological Association has received very encouraging promises of support for the memorial volume to the late Sir Frederick Mott, and it is hoped that the book may be ready in the early autumn. The title suggested is "Contributions to Psychiatry, Neurology, and Sociology. Dedicated to Sir Frederick Mott by his Colleagues, Friends, and former Pupils." The publication has been entrusted to Messrs. H. K. Lewis and Co., Ltd.

APPLICATIONS are invited by the University of Glasgow before April 1st, 1929, for the Harry Stewart Hutchison Prize of about £50, which is offered for the best original research in a branch of medical science relating to children. The prize is open to medical graduates, of not more than ten years' standing, of all British and colonial universities. Further information with regard to this prize will be found in last week's advertisement columns.

THE Board of Education has published in pamphlet form a list of certified special schools, recognized institutions for the training of the blind and other defective children, and nursery schools in England and Wales. The schools are grouped according to type and arranged in counties, details being given of the accommodation available and the average attendance in 1926-27 in each case. Copies of the list may be obtained from H.M. Stationery Office, price 1s.

THE Cambridge University Press announces for early publication Part II of Professor Joseph Barcroft's work on *The Respiratory Function of the Blood* and a revised edition of Dr. F. D. Drewitt's *Romance of the Apothecaries' Garden*.

INFORMATION regarding the special study tour for medical practitioners to the spas and health resorts of Italy, to which reference was made on May 5th (p. 787), may be obtained from the Italian Travel Bureau, 16, Waterloo Place, Regent Street, S.W.1, where bookings may be effected and all arrangements completed. The tour will extend from September 5th to September 21st, covering a number of places of interest in Lombardy and Piedmont, including the Italian Riviera and the Italian lakes.

THE eighth international congress of dermatology and syphilography, which was to have taken place in 1915, three years after the congress held in Rome in 1912, will meet at Copenhagen from August 5th to 8th, 1930. Further information can be obtained from the general secretary, Dr. S. Lomholt, Raadnisplads 45, Copenhagen.

THE French league against the venereal peril will hold a congress at Nancy from May 29th to 31st, when the following subjects will be discussed: the history of syphilis, the education of the public, the antisiphilic dispensary, and organization of means for combating inherited syphilis. Further information can be obtained from Dr. Spillmann, Faculté de Médecine, Rue Lionnois, Nancy.

DR. TAILLENS, professor of diseases of children at Lausanne University, has been nominated Chevalier of the Legion of Honour. Professor Manuel Quintela, formerly dean of the faculty of medicine of Montevideo, has been nominated officer of the Legion.

THE 125th anniversary of the birth of the chemist Justus Liebig, who was born at Darmstadt on May 12th, 1828, is to be celebrated by rebuilding with the original material the house in which he was born, and the addition to it of a museum.

TRACHOMA is prevalent in Tokyo, where there are now over 330,000 cases in a population of about two millions.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the *British Medical Journal*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER  
(Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*); telephone: 62550 Dublin, and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*); telephone 24361 Edinburgh).

### QUERIES AND ANSWERS.

#### CRAMP AFTER SCIATICA.

DR. S. A. EWING (Melbourne, Australia) writes: In reply to the query of "K." in your issue of March 10th (p. 430) for suggestions as to the relief of cramp following sciatica, for such or any form of cramp complete relief will often follow the wearing of woollen socks into which the pyjamas are tucked at bedtime. Those wearing stockings may find it advisable to carry them well above the knees. Undue exercise should be avoided, though with the above method immunity may result even after moderate fatigue.

#### MEDICAL FACILITIES ON MOHAMMEDAN PILGRIM SHIPS.

"PORT SAID," who is returning home from the East after a voyage as ship's surgeon, is desirous of having the experience of any member of the profession who has acted as surgeon on board a Mohammedan pilgrim ship to Jeddah. He would like to know the sickness and death rate, if any, and what sick comforts were allowed and given on board; also if the sick pilgrims were treated with kindness by the ship's officers. His own experience of a single voyage has been wretched, and he wonders what the case has been with others.

#### TREATMENT OF CHRONIC NASOPHARYNGEAL CATARRH.

"C. C." invites suggestions for the treatment of chronic nasopharyngeal catarrh in a patient suffering from chronic phthisis. Various douches and sprays have been tried without benefit. Nasal surgeons whom he has consulted do not advise surgical treatment.

#### A HOSPITAL STERILIZER.

DR. R. H. S. MARSHALL (Oswestry) asks for information as to the best "sterilizer" which would take clothes and bedding and be suitable for an isolation hospital of twenty-four beds, chiefly used for scarlet fever and diphtheria. Central heating is already installed, and gas is laid on, but not electricity. He would like to know type, approximate cost, and where it can be obtained.

#### RADIOGRAPHY OF VISCERA.

DR. F. F. ROBERTS (Cambridge) writes: "Cowal" (May 19th, p. 884) will find the information he requires on orthodiagraphy of the heart in a small book by Vaquez and Bordet, *The Heart and Aorta: Studies in Clinical Radiology*. The English translation is published by Messrs. Humphrey Milford, Oxford University Press. There are, of course, a number of works on radio-scopic of the chest and abdomen. A standard work, and the best which I have seen, is Assmann, *Klinische Röntgendiagnostik der inneren Erkrankungen*. Unfortunately there is no English translation. A good account of the alimentary canal is also given in *The Roentgen Diagnosis of Diseases of the Alimentary Canal*, by Carman (published by Messrs. Saunders).

#### INCOME TAX.

"P. H." inquires what will be the position of a man who retires on a pension of £320 per annum, having an income of £200 from dividends, taxed before receipt, and entitled to an allowance for one child and a dependent relative.

\* \* If the wife be living the total allowances due for 1928-29 are: Personal £225, earned relief £53, child £60, dependant £25

total £363. There will therefore be no tax due on the £320 pension, and repayment of tax can be claimed against the dividend to the extent of (£363-£320=) £43 at 4s. and (£200-£43=) £157 at 2s.—that is, £24 6s. in all.

#### Repayment of Loan.

"X. Y. Z." is paying about £100 a year out of his earnings in repayment of a loan obtained for the purchase of a share in a partnership. He asks: "Am I liable to be assessed on this sum of £400?"

\* \* "X. Y. Z." is, of course, assessable on his earnings—that is, on income, not on outgoings; the real question is, Can he deduct the £400 in reckoning the amount of his earnings? The answer is that he cannot. That payment is an application of his income, and not an expense incurred in earning it. The amount represents a payment of capital, and cannot be deducted by him or be assessed to tax as income of his partner.

### LETTERS, NOTES, ETC.

#### SEA-SICKNESS.

DR. F. GREENE KELLY writes: As a ship's surgeon of some years' experience I quite agree that so far we have no remedy for mal de mer, though the patient can greatly assist matters by taking calomel at night, followed by a saline next morning. Whether anything be gained by remaining on deck in the open air or being confined to the cabin largely depends on individual idiosyncrasy. I have had patients who, as long as they were confined to their cabin, showed no improvement until they were brought on deck; exactly the reverse occurred in those cases which tried the "fresh air treatment." The same applies to the drugs applied as remedies; sodium bicarbonate, bromides, atropine, and tincture of iodine have been employed with very varying degrees of success.

#### INFECTION AMONG CHILDREN IN CASUALTY DEPARTMENTS.

DR. THOMAS BLEZARD (Mansfield) writes: The correspondence on the possible spread of small-pox by "casuals" brings to my mind a state of affairs which existed—and very likely still exists—at a large general hospital where I once did "locum" as house-physician. As at most general hospitals, the casualty department was always crowded with mothers bringing children suffering from almost any complaint. While waiting to be seen the mothers naturally mingled generally, and the children did likewise. Later, in very obvious scarlet fever rash might be noticed on a child; it was then isolated and was soon on its way to an isolation hospital. But did this action negative any possible—and in my opinion probable—chance of infection to the other children in the waiting room? In my short stay I came across scarlet fever, measles, and, I think, diphtheria. It is possible that the resilients found other types of infectious disease. Whether small-pox has been met with in this way I cannot say, but it is a possibility not to be ignored. Probably similar conditions prevail in many general hospitals where poor people take their sick children to the casualty department before calling in a doctor. Some method should be adopted whereby children with rashes or sore throats would be isolated on entering the hospital and would not mingle with other patients. The casualty officer should be notified at once of such cases.

#### MEDICAL GOLF.

AT the annual meeting of the Manchester and District Medical Golfers' Association, on May 16th, the challenge cup was won by Dr. J. S. Brown of Wigan. The Walter Gold Medal for the best scratch score was won by Dr. T. D. Burt of Gorton, who had a gross of 78. Dr. C. R. J. Boland of Ancoats Hospital, Manchester, grossed the Walter Silver Medal for the best gross score by players with handicaps of 10 and upwards.

#### TREATMENT OF INJURIES ROUND THE ELBOW-JOINT—A CORRECTION.

IN the report received by us of Mr. J. F. H. Stallman's clinical demonstration to the Gloucestershire Branch, which was published in our columns on May 12th (p. 802), there appears to have been an error. Mr. Stallman was quoted as saying that, in his opinion, all injuries round the elbow-joint should be treated by prolonged immobilization in plaster. We are asked to explain that his statement with regard to prolonged immobilization in plaster applied only to myositis ossificans, and that his reference to injuries round the elbow-joint was to the effect that, no matter how trivial, they should be treated with proper respect.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 227.

## Observations

ON

## NASAL AND ORAL FOCAL SEPSIS IN THE ETIOLOGY OF GASTRO-INTESTINAL AND PULMONARY INFECTIVE DISEASES.\*

BY

PATRICK WATSON-WILLIAMS, M.D. LOND.,

CONSULTING SURGEON TO THE EAR, NOSE, AND THROAT DEPARTMENT, BRISTOL ROYAL INFIRMARY; LATE LECTURER IN DISEASES OF THE EAR, NOSE, AND THROAT, UNIVERSITY OF BRISTOL;

AND

F. A. PICKWORTH, B.Sc., M.B.,

DIRECTOR OF JOINT BOARD OF RESEARCH FOR MENTAL DISEASES OF THE UNIVERSITY OF BIRMINGHAM.

(Pathological Specimens and Report.)

The term "focal sepsis" is usually applied in its clinical sense to established pyogenic infection such as occurs when an initial infective invasion, having overcome systemic and tissue defensive reaction, persists as a chronic localized infection. Nevertheless in patients with nasal passages choked with polypus, or copious purulent gingivitis round the necks of living teeth, or periapical dental abscess, one often looks in vain for systemic complications; the copious outpouring of polymorphonuclears seems a measure of successful local resistance to the focal infection. Chronic bacterial toxæmia and subinfection is most prone to arise from chronic latent focal infections, such as frequently occur in nasal sinusitis, with relatively non-purulent discharge (sinus infection without pus in some degree does not exist), or periapical dental sepsis, often with no pus at all. Hence the existence of a causal focal sepsis in pulmonary or gastro-intestinal infection is often to be discovered only by careful investigation.

Sepsis of the mouth, pharynx, and nose may affect the lower respiratory tract or gastro-intestinal tracts (a) by direct spread of infection along the mucous membranes, through the larynx and trachea; (b) by the blood stream or lymph-vascular infection; (c) by inhalation of septic particles or secretions, or by the swallowing of enormous numbers of organisms.

## GASTRO-INTESTINAL INFECTIONS.

## Organisms Swallowed.

That patients may swallow immense numbers of septic organisms with impunity is certain, for the normal acid gastric secretion is a potent antiseptic barrier; but if the mass infection is continued it fairly frequently results in gastric catarrh or gastritis, with hypochlorhydria, constipation, diarrhoea, or recurring colitis. It would seem likely that naso-oral infection may originate local gastric or duodenal ulcers; or, in a relaxed sphincter of Oddi, or, as more commonly appears to happen, appendicitis. Again, such gastro-intestinal infections may be indirectly determined by toxæmia with resulting endocrine exhaustion.

## Infection Conveyed through the Blood Stream.

In such cases pyogenic organisms apparently display an elective affinity for the regions involved—for example, the gastro-intestinal tract—which the researches of Rosenow have gone far to explain and to prove.

It appears, at any rate, a reasonable assumption that, in many cases, a chronic subinfection is commonly set up in the gastro-intestinal tract, although in many a patient a relative auto-immunization renders him merely a "carrier" until, perchance, exposure to cold or some intercurrent factor determines an exacerbation of what is really a long-standing infection. When eight years ago, in 1920, in a contribution to this society, I urged the importance of nasal sinus infection as a causal factor in appendicitis, and also of gastric and duodenal ulcers, an analysis of 90 consecutive cases of sinusitis in my own practice showed that no fewer than 14 had undergone appendicectomy, 2 had operation for duodenal ulcer, and

2 patients had gastric ulcer. Further evidence was included in my 1925 Semov Lecture.

I now turn to quite recent observations of the general surgeon and physician in support of my thesis that naso-oral focal sepsis is to be reckoned among the primary sources of gastric and duodenal ulcer, cholecystitis, and appendicitis. Mr. A. H. Burgess,<sup>2</sup> writing on chronic ulceration of the stomach and duodenum, after referring to the work of Rosenow and of Wilkie, says that "these researches emphasized the importance of a careful search for any focus of infection in the teeth, tonsils, nasal sinuses, or elsewhere before operation." Professor Wilkie<sup>4</sup> stresses the frequent simultaneous association of gall-bladder and appendix infection, "not consecutive but simultaneous blood-borne infections, usually of streptococcal type." Dr. Izod Bennett,<sup>5</sup> writing on the treatment of gastric ulcer, says that "oral sepsis is probably the most important cause of gastric and duodenal ulcer." As long ago as 1900 Dr. William Hunter<sup>2</sup> urged the importance of oral and nasal sepsis as causes of serious gastric and intestinal disease. How can one reconcile the large percentage of gastric and duodenal ulcers that Hugh MacLean<sup>6</sup> cured by "intensive alkaline treatment" with the current view that absolute or relative hypochlorhydria, and therefore diminution of the antiseptic barrier in the stomach normally ensured by the free hydrochloric acid there, leads to the uninhibited swallowed pyogenic organisms infecting the gastric mucosa or that of the duodenum? Are there two distinct groups of gastro-duodenal ulcer—those due to hypochlorhydria, non-infective, with ulceration from the surface, and those due to blood-borne infection, in which, as in Pickworth's specimens of G. S., the infecting organisms invade the deeper layers of the gastric mucosa and not the surface epithelium? It seems probable that appendix infection results from swallowed organisms, for there the intestinal contents are normally alkaline, while infective gastro-duodenal ulcers are often blood-borne, and thus the frequent concomitance of appendicitis and gastro-duodenal ulcers of infective origin might be explained.

Of the specimens of sphenoidal sinusitis that Dr. Pickworth brings before us to illustrate the purport of this paper, those from G. S. might be justly termed a "human parallel of Rosenow's experiments," for in this case a chronic diplococcal infection has been traced, invading the sinus mucosa from the surface, and spreading to the pituitary capsule and gland; in the same case similar diplococci are also demonstrated in the deeper layers of the evenly spaced haemorrhagic patches in the gastric mucosa. Furthermore, in this and other specimens the diplococcal infection, traced to the pituitary, explains the evidences of endocrine disturbance, since the superjacent hypothalamus is the region held to control many of the basal metabolic processes. (See Fig. 9.) These observations of Pickworth, corroborating similar researches by Logan Turner, Reynolds, and others, point to infection by the blood stream as being the most likely pathway of many sub-infections, rather than infection by inhaled or swallowed organisms. Why organisms in the blood stream should have an elective affinity for certain regions or organs we do not know, but that such elective affinity is shown Rosenow's researches leave little room for doubt. Furthermore, this same elective affinity of certain strains of infective organisms for certain tissues is supported by clinical experience—as, for instance, in epidemic influenza, which in one epidemic tends to involve the lungs, in another the gastro-intestinal tract, and in yet another shows a proclivity to cerebro-spinal complications.

## Dr. Pickworth's Specimens of Sphenoidal Sinuses and Gastric Mucosa.

These demonstrate, macroscopically and microscopically, the association of infective conditions of the sphenoidal sinus with (a) lesions of the stomach mucosa, and (b) changes in the pituitary gland. (Several other specimens shown are excluded by limitations of space.)

*Specimen G. S.*—This shows peculiarly evenly spaced haemorrhages in the stomach mucosa. The haemorrhages are near the surface, superficial to small thrombosed blood vessels. The mucosa, except from the haemorrhages, is of good colour.

\* Read at meeting of the Bath and Bristol Branch of the British Medical Association at the University of Bristol on March 28th, 1928.

resembling a leopard's skin (Fig. 1). The thrombosed vessels contain diplococci (Fig. 2), although very sparsely distributed. The sphenoidal sinus (Fig. 3) shows a much thickened membrano containing large masses of cocci invading the deeper tissues, usually without, but occasionally with, lymphocytic infiltration (Figs. 4 and 5). These cocci are apparently identical with those invading the stomach and also the pituitary capsule and gland.

*Specimen W. J.* (Fig. 6) shows haemorrhages in process of absorption, and represents an intermediate stage between the above specimen and the following.

FIG. 1.—Stomach mucosa (G. S.). Multiple superficial haemorrhages beneath which were thrombosed vessels containing diplococci.

*Specimen A. L.* (Fig. 7) shows multiple deep pitting—really small ulcers—and an occasional dark area shading off into the surrounding tissue. This is probably an example of resolution of the "leopard's skin" condition, in which the haemorrhages and thrombosed vessels have been digested with accompanying attempt at repair.

The partial resolution seen in specimens W. J. and A. L. indicate that the haemorrhages of G. S. are not merely a terminal condition.

*Specimens J. C. and M. R.* are examples of sphenoidal sinusitis, one associated with capillary haemorrhages (diapedesis), the other with multiple pin-head lymphocytic nodules in the gastric mucosa. (Illustrations of these specimens not reproduced.)

FIG. 2.—Stomach (G. S.), showing organisms amongst blood corpuscles from thrombosed blood vessel. These organisms are of similar microscopic appearance to those seen in the sinus membrane.

#### PULMONARY INFECTIONS.

The rhinologist has long been familiar with the anaemia, cough, expectoration of mucus, sometimes streaked with blood, loss of appetite, wasting, nocturnal fever, and sweats that may occur in chronic purulent nasal sinusitis, often with localized bronchitis, and while in earlier and less marked cases early tuberculosis is mimicked, in old-standing cases they rather suggest advanced pulmonary tuberculosis. Moreover, these chronic septic sinuses are prone to cause recurrent pulmonary infections, till in turn a subinfection of the lung becomes a chronic focal infection. Dr. Young<sup>2</sup>

says very truly: "Nasal sepsis may give rise to symptoms and signs curiously mimicking those of early apical tuberculosis—with definite signs in the lungs, particularly at the apices, which clear up when the nasal condition has been effectively treated."

My experience of sinus infections leads to the conviction that in many patients with constant recurrence of bronchitis the source of infection lies in the chronic sinusitis, where the established infection with relative auto-immunization renders the patient a sinus "carrier"; in

FIG. 3.—Sphenoidal sinus (G. S.). The mucosa was thickened and showed invasion by organisms. (See Figs. 4 and 5.)

course of time, the same seems true of pulmonary subinfection, when the patient becomes a lung "carrier."

We know that in chronic pyogenic infections of the mucosa of the sinuses the organisms may invade the submucosa and, with quiescent intervals without symptoms, activate from time to time under the influence of climatic conditions or the symbiosis of a hetero-infection—as, for instance, influenza, measles, etc. There is reason to believe the same obtains in pulmonary infections, and this explains some of the pulmonary complications following general anaesthesia, which are not by any means always due to infection from above, but may be due to sensitization

FIG. 4.—Sinus membrane (G. S.), showing masses of organisms invading the membrane.

of pre-existing lung infection, though any established focal sepsis in the nose and mouth is a constant menace to the lower respiratory tract. It is hardly necessary to discuss the recognized fact that tonsillar sepsis or tuberculosis may spread to the hilum and peribronchial tissues of the lung, and it appears certain that lung complications of a nasal sinus infection are often the result of blood stream infection.

Familiar experience of the catarrhal infection known as the common cold illustrates the tendency of the naso-oral catarrh to spread to the lower respiratory tract, particularly in certain individuals whose colds always spread to the

chest; in these there is often an acquired liability to frequent recurrence, and, moreover, in the same pulmonary area each time. Now, as Batty Shaw<sup>1</sup> observes, we are not sure the recurrent attacks in such patients are the result of reinfection from outside, while many become chronic bronchitis, and are, in fact, "carriers." "The infection is a reinfection from within."

That bronchiectasis is very frequently due to secondary infection from naso-oral sepsis is now accepted, and it is probable that early and less marked forms of bronchiectasis are not seldom present, when signs and symptoms are as yet too indefinite to permit of an exact diagnosis, perhaps due to pressure in coughing acting on a bronchial musculature and tissues weakened by infective processes.

It should hardly be necessary to emphasize the importance of recognizing and removing focal infection of the mouth or nose in cases of pulmonary tuberculosis. But there would seem to be good grounds for suspecting that sometimes patients with such focal infections, with pulmonary complications diagnosed as phthisis, despite the failure to find tubercle bacilli in the sputum, are in reality not tuberculous at all, but examples of sepsis infection. Such pulmonary cases may be clinically indistinguishable from the so-called phthisis without tubercle bacilli; they benefit greatly, and may become cured by sanatorium methods; but such methods are immensely assisted by the recognition and removal of the causal focal infection, without which every method of treatment is prone to prove abortive.

Curiously enough, reports on the sputum, which may be teeming with virulent pyogenic organisms, are usually returned "negative" unless a few stray tubercle bacilli can be identified, often only after repeated examination. Yet, even in cases that are truly tuberculous, the association of other pathogenic organisms is by no means a negligible factor. In every case of clinical pulmonary tuberculosis, whether tubercle bacilli are demonstrable or

surgeon, or the laryngologist, yet seldom if ever conjointly. The following are three good examples in which the case-histories suggested focal infection.

The first came under my care last October. He was a man, aged 61, in active pursuance of his profession, which brought him constantly before the public. Apparently fit when I saw him then, he had on so many occasions of recent years been laid up with attacks of febrile nasal catarrh, which "laid him out" and caused severe financial loss, that he was in constant dread of their seemingly inevitable recurrences. Twenty-seven years previously, in 1800, he had left antral empyema due to diseased teeth. These were extracted, the alveoli opened, and a gold tube inserted; through this daily lavage was carried out for about ten years, when, being considered no longer necessary, the tube was removed and the opening allowed to close. Two years later, in 1912, he consulted a colleague for sensations in the antral region, but transillumination was negative and he was reassured. Again, four years later, occasional colds and laryngitis and slight cacosmia made him seek a further consultation; but once more transillumination and likewise a skiagram were both negative. In 1921, with a severe febrile attack abroad, he had a septic abscess on his foot, and again in 1922 and 1923 slight cacosmia.

In January, 1923, he underwent appendicectomy in London for acute appendicitis, and five weeks later an operation on his gall-bladder was performed by the same surgeon.

In April, 1927, he felt and looked ill and neurasthenic. He could not concentrate, and had difficulty in memorizing, which for him in his work was most unusual. A few weeks later he had a severe feverish cold; he was in bed ten days, as he had a pneumonic patch and rusty sputum—streptococci were cultured from a pharyngeal swab. Regaining his relative auto-immunization he returned to

work; but six months later, though in fair health, he was still in constant dread of further breakdowns.

Now the history of his recurring febrile colds, appendicitis, cholecystitis, and phases of poor memory, pointed so strongly to a focal infection that, despite the absence of any nasal abnormality or catarrh, using the suction syringe, exploration of the left antrum revealed a pure growth of pneumococcus with slight phagocytosis, though his right antrum was sterile. It would seem that this pneumococcal focus was the causal factor of his septic pneumonia, probably of the previous appendicitis and cholecystitis, and likewise of the recurring febrile attacks that had proved so disastrous in his career. Yet his various medical attendants had apparently failed to inquire for those data in the long history which, taken as a whole, seem to afford such a useful diagnostic guide.

FIG. 5.—Sinus membrane (G. S.), showing organisms invading membrane with cellular reaction (the large dark masses are lymphocytes).

FIG. 6.—Stomach mucosa (W. J.). Haemorrhages as in Fig. 1, but showing early stage of resolution.

not, careful inquiry for the existence of focal infection ought never to be omitted.

#### The Importance of Case-History in Focal Sepsis.

It is very instructive to observe how a patient's medical history alone, taken over a long period, may in itself suffice to suggest some chronic septic infection, ever and anon cropping up, with quiescent intervals due to relative auto-immunization, but manifesting its existence by recurrences which, on each of several occasions, have separately engaged the attention of the physician, the

FIG. 7.—Stomach mucosa (A. L.). Haemorrhages as in Figs. 1 and 6, but showing later stage of resolution. Many haemorrhages have entirely disappeared, leaving superficial erosion and deep pits.

Miss D., aged 46, suffered from chronic rheumatoid arthritis in shoulders, wrists, fingers, and knees, of twenty-seven years' duration, beginning at the age of 14. She also had chronic rhinitis of much the same duration, yet, although she consulted laryngologists, there was never sufficient evidence to warrant any operative treatment till 1916, when the sphenoidal sinuses were proved to be infected with *Staphylococcus aureus* and *Streptococcus brevis*. Meanwhile, however, she had recurring colitis, and removal of the appendix was followed by pneumonia. From the time her sphenoidal sinuses were opened and drained the arthritis definitely improved and her health has remained uninterruptedly good ever since.

W. M., aged 29, had severe influenza in 1901, appendicitis in 1903, and appendicectomy in 1907, followed by prolonged insomnia and mental depression. He returned to work, but in 1911, after a mild attack of influenza, headaches, and depression with suicidal impulses, culminating in delusional insanity, he was again unable to work. He was found to have staphylococcal infection involving all his nasal sinuses. The sinuses were radically operated on to eliminate all the focal sepsis, and after some months he

FIG. 8.—Sphenoidal sinus (M. L.), showing perforation of pituitary fossa from sphenoidal sinus. Note especially the bony ridge within the fossa indicative of long-standing infection.

lost his delusions, regained his mental balance, and returned to work. He remained in uninterrupted health, and has occupied the position of bank manager for sixteen years.

These three cases, after a long history of nasal infection with ever-recurring complications—extending over several years, and including arthritis, appendicitis, pneumonia, neurasthenia, and insanity—completely recovered, and the oft-recurring infections abruptly ceased with the removal of what certainly would appear to have been the common causal factor of all their illnesses, nasal, pulmonary, and abdominal. The appendicitis cannot be regarded as mere coincidence, and each case in its entirety is a clinical picture representing the long-drawn-out history of a chronic low-grade focal infection.

Now, if these naso-oral focal infections do cause such serious complications, their early recognition and prompt

FIG. 9.—Pituitary stalk (M. L.), showing diplococci at a, b, and c. This suggests a new path of infection of the hypothalamic region of the brain from a sphenoidal sinusitis.

removal may prevent these subinfections of the pulmonary and gastro-intestinal tracts, for a latent focal infection is truly "a wolf in sheep's clothing." How much serious illness could be prevented by regarding chronic septic infections more seriously without waiting for dangerous complications to point the moral!

If I have wandered into the domain of the physician and surgeon my purpose has been to show how even the rhinologist, ploughing his lonely furrow, is by his work so interlinked with his colleagues that no territory can be regarded as lonely, and that in medicine there is but one field, which ever calls for team work.

## AN OUTBREAK OF PARATYPHOID B FEVER PRESENTING NOVEL FEATURES.

BY

A. GRAHAM-STEWART, M.B., CH.B. ABERD.  
With Notes on the Bacteriological Aspects

BY

PHILIP MANSON-BAHR, M.D., F.R.C.P.,  
AND

T. R. GODDARD, M.R.C.S., L.R.C.P.

THE subject of the present study was a limited outbreak of paratyphoid fever which occurred in May, 1925, in a preparatory school, and which, in certain aspects, presented novel features. The boys, numbering sixty, assembled for the summer term on May 5th; some ten days later cases of fever began to occur, and continued to do so till May 29th, when the epidemic ceased. In all, twenty-three cases were notified, while none of those attacked was dangerously ill. The incubation period of this particular epidemic could be accurately ascertained as being from ten to twenty-four days.

The early symptoms were not of a serious nature; for the most part they consisted of a transient headache and a high temperature (102° to 104° F.), coupled with an extraordinary appearance of well-being. At first the headache, the high temperature, and the relatively slow pulse suggested influenza. By the fifth day from the commencement of the epidemic "rose spots" were already visible. At this time, too, a positive agglutination to *B. paratyphosus* B was obtained, and a blood culture performed gave a positive growth of this organism. The diagnosis was therefore clinched.

#### CLINICAL SYMPTOMS.

In contradistinction to other zymotic diseases the absence of any distressing features at the commencement of the illness was a point to be noted. Save for a few days at the end of the first week appetites and spirits appeared to be unaffected. In the early stages this very absence of symptoms may be misleading and cause delay in diagnosis. The pulse-temperature ratio was typical of the enteric group. In one boy with a temperature of 105° F. the pulse rate registered 100, in another with 101° F. it was 80, and in a third with 104° F. it was 96. In one of the cases transitory dizziness was complained of, and in 15 per cent. there was vomiting. In one only was there a rigor, and, with the exception of headaches, no other complaints. The onset of the paratyphoid fever was sudden; there were no prodromal symptoms. Constipation was the rule, and the motions did not in the least betray the nature of the illness. The tongue was coated with a thick white central fur. In only one case, a boy with a temperature of 105° F., was mild delirium noted.

**The Exanthem.**—The first spots appeared at the end of the fifth day; after that 75 per cent. of the cases developed a roseolar rash confined to the chest, abdomen, back, and flanks. In one case the rash was so generalized that the body was covered, with the exception of the soles of the feet, the hands, face, and neck. In 25 per cent. no rash whatever developed, and in a few instances its appearance was delayed till the fourteenth day.

**Pyrexia.**—In typical cases the fever was of a remittent type for fourteen days; in some cases for seventeen or eighteen days; in the milder forms it lasted from seven to ten days. Defervescence took place by lysis. Palpable enlargement of the spleen was noted in every case from the fifth day onwards. In some the splenomegaly was obvious, and extended four fingerbreadths below the costal margin. In a third of the cases epistaxis was noted. No complications were observed save a severe general myalgia and cardiac dilatation in one boy who had previously suffered from an enlarged heart. Bronchitis and pulmonary complications were completely absent.

## TREATMENT ADOPTED.

Treatment was based on general lines. The diet was not excessively rigid; it consisted of three pints of milk, reinforced with plasmon, biscuits and rusks, bread-and-butter, custards, raw eggs, milk puddings, and a tablespoonful of glucose. Lemonade was freely given.

**Drugs.**—A 2½ minim capsule of oil of cinnamon was given every two hours, and 5 grains of urotropine three times daily. In order to counteract the constipation an ounce of petrolagar was given twice daily. At the termination of the illness the faeces and urine of each boy were examined bacteriologically three times, and in only one case was a positive culture of *B. paratyphosus* B obtained.

## PREDISPOSING CAUSE.

The limited nature of the outbreak, its occurrence amongst a proportion of the schoolboys, the absence of any other ascertainable source of infection, the probability that all twenty-three cases were infected from the same source, at the same time, rendered it almost certain that some article of food was responsible for the outbreak. After eliminating other possible articles of food, suspicion fell on one particular Italian cream cheese, which was eaten on the day of assembly, May 5th. A very careful search for a possible carrier was undertaken, but proved useless.

Two previous outbreaks of fever due to eating cheese have been recorded. Ford and Walker<sup>1</sup> record an epidemic of paratyphoid fever in Missouri; it consisted of forty-four cases and extended over twenty-eight days. Macaniky<sup>2</sup> in the Dover epidemic of July, 1922, which affected 126 individuals in forty-three families, expresses the opinion that the infection was due to Gaertner toxins contained in cheese.

## LABORATORY INVESTIGATIONS.

**Blood Culture.**—Blood culture was performed in five instances, and was successful on the fifth and eighth days of the illness.

**Serum Agglutination Tests.**—The first batch of cases consisted of seven boys who had been ill for eleven days; the second consisted of four boys, two of whom had been ill for five days and two for three days. The serums of all the above strongly agglutinated emulsions of *B. paratyphosus* B when tested out on "Garrow's agglutinator" in dilutions of 1 in 10 upwards. The clinical appearances of the sick boys coincided with the results of the agglutination tests. Following upon the outbreak, the blood of the remaining boys, together with that of the masters, domestic staff, and outside attendants (eighty-four persons in all), was tested, with a negative result; but in two apparently healthy boys, who at the time were playing in the fields, the serum was found to agglutinate *B. paratyphosus* B in a dilution of 1 in 10, while the spleens of both were definitely enlarged. Both of these boys, who, as a result of the test, were regarded with suspicion, developed paratyphoid B fever within the next five days. On the other hand, in the case of eight other boys who developed paratyphoid fever during the ensuing five days no agglutination was obtained; but, after a further lapse of a fortnight, when again tested, a positive agglutination in dilutions of 1 in 80 to 1 in 160 was obtained. In one instance a positive agglutination against typhoid, paratyphoid A, and paratyphoid B was obtained, and it was satisfactory to ascertain on inquiry that this boy had received a triple inoculation some two months previously in Egypt.

The object of setting forth an account of this epidemic in detail is to show that, with the technique employed, the investigation of such an outbreak can be concluded within the comparatively short period of forty-eight hours. It is doubtful whether by any other technique results of such importance could be obtained with like certainty and speed. The main points elicited were: (1) The trustworthiness of this method of macroscopic agglutination when applied on a large scale. (2) The fact that in two instances the blood serum gave a positive agglutination to *B. paratyphosus* B at a considerable period before the symptoms of the disease developed, and that it was in one instance accompanied by a palpable enlargement of the spleen in the incubation period of the disease.

## Method of Determining the Serological Reactions of Patients and Contacts in the Epidemic of Paratyphoid B Fever.

Agglutination tests were performed on Garrow's agglutinator, a method we have practised with satisfaction since the perfection of the apparatus in 1916, and subsequently we employed it as a means of diagnosis throughout the great war. The simplicity of the instrument, and the ease with which all the necessary material for performing agglutination tests can be carried about, rendered it invaluable for use under conditions of active service. Garrow's agglutinator<sup>3</sup> is to some extent based on Broughton-Alecock's<sup>4</sup> slide method. This method of "agglutination forcée" alone makes possible the performance of a large number of tests in a minimum of time. The reaction is macroscopic and easily visible to the naked eye. When controlled by the tube method of agglutination it has shown itself to be equally specific, though it must be admitted that the "end-point" never reaches so high a titre as in the former method. False or "pseudo-reactions" are apt to occur only when very low dilutions of the serum—that is, under 1 in 10—are employed.

The formalinized bacillary emulsions used were prepared from type cultures supplied from the National Collection of Type Cultures at the Lister Institute, and were adequately tested, as regards their agglutinability, before the investigation was commenced.

The object of testing the entire school population for agglutinins of paratyphoid B fever was based upon the supposition that such a reaction will normally occur in a carrier of the infection. It is quite true that if a person has suffered from a mild attack of paratyphoid B fever, and continues to excrete the organisms, his serum will probably agglutinate the paratyphoid B bacillus, but this does not necessarily take place in the "symptomless carrier," who, though not showing any clinical signs of infection, nevertheless harbours the organisms, so that the agglutination test does not always provide a sure means of detecting such a "carrier."

The serum of eighty-four individuals was submitted to the test, and the method of applying it on such a large scale was as follows: The blood required was obtained by pricking the pulp of the finger with a sterilized "bare-tip" needle. By gentle massage along the length of the finger sufficient blood was obtained to fill an ordinary capillary tube with a bulbous enlargement in its middle.

The sick boys were visited in their rooms in order to collect the sample of blood. The remainder of the school-boys, masters, and domestic staff were paraded. As each individual came forward the finger was pricked and the blood collected in the capillary tube. The tube ends were then carefully sealed with sealing wax, and finally each tube was labelled with the respective individual's name. In this manner samples of blood from the entire school were rapidly obtained. The next step consisted in centrifugalizing the blood in order to obtain clear serum. The capillary tubes containing the blood were placed in both buckets of the centrifuge, so that the process of centrifugalizing the whole of the specimens was thus rapidly carried through. It may be pointed out here that the amount of clear serum required for the test, when using the Garrow agglutinator, is very small, two drops being ample.

After obtaining the serum, dilutions were made with normal saline; one drop of the diluted serum of each individual was placed in each of three adjoining divisions on the Garrow's slab, and to these were added respectively one drop of typhoid bacillary emulsion, one drop of paratyphoid A emulsion, and one drop of paratyphoid B emulsion. Since the slab is divided into thirty separate divisions it was possible to put up the serums of ten individuals against the typhoid and paratyphoid A and B emulsions at one and the same time. The slab was then transferred to the box and rotated for three minutes by means of a special mechanism, thus bringing the serum into intimate contact with the bacillary emulsion. As a rule the results are sharp and clear. In the case of a positive reaction the mingled drops of bacillary emulsion and serum are seen to contain innumerable whitish particles

consisting of agglutinated masses of the germs. In the case of a negative reaction, the emulsion is smooth and free from particles. In this manner the whole of the eighty-four serums were quickly tested and those giving a positive reaction carefully noted.

## NOTES ON THE TREATMENT OF ORAL AND RECTAL CANCER BY RADIUM.

BY

B. T. ROSE, CH.M., F.R.C.S.ED. AND ENG.,  
 ASSISTANT SURGEON, GENERAL HOSPITAL, BIRMINGHAM.

By the courtesy of my colleagues at the General Hospital, Birmingham, and with the help of the Birmingham Branch of the British Empire Cancer Campaign, I have been enabled to treat a number of cases of advanced oral and rectal carcinoma with radium. The radium has been loaned to the hospital by the Medical Research Council, and I am indebted to this body for permission to publish these notes, which embody much that has been previously communicated to the Council in the last report from the department. The figures deal with cases treated over a period of two years (1926-27), but include a few cases treated before this date which have been kept under continued observation and treatment during the period stated.

### CANCER OF THE MOUTH.

The number of cases admitted to the department was 39. Of these, 2 have been treated too recently to be included in these notes, 1 proved to be a simple naevoid tumour of the tongue and was easily cured by radium, 7 were unsuitable or refused treatment; 29 cases are thus left available for consideration.

**Age and Sex Incidence.**—The average age of the patients was 59 years; the youngest was 46 and the oldest 70; all except two had passed the age of 50. Males greatly preponderated, there being 27 to 2 females. It is difficult to account for this, because dental sepsis appears to be equally common in both sexes in hospital practice.

**Predisposing Factors.**—Dental sepsis is undoubtedly a predisposing factor. Severe dental sepsis was present in 20 cases (69 per cent.), and in 9 of these there was a direct history of prolonged irritation at the site of the ulcer by a jagged tooth; moderate dental sepsis was present in 7 cases (24 per cent.); there was no history or sign of dental sepsis in 2 cases (7 per cent.). It would thus appear that dental sepsis is a powerful factor in the causation of epithelioma of the mouth. There can be no doubt that mouth cancer is more frequent among patients of the hospital class, who rarely, if ever, use a toothbrush and who seek no advice for dental caries. The importance of syphilis as a factor in the production of the disease was not brought out in this series of cases. In only 5 of the 38 cases of new growth admitted was the Wassermann reaction positive, and in only one of these five was a syphilitic lesion of any type found; this was marked lingual leucoplakia, a carcinoma developing on a thickened patch in the centre of the tongue.

**Microscopical Verification.**—A section was obtained in 27 out of the 29 cases considered; all were squamous epitheliomata. The two cases not submitted to section were clinically unmistakable cases of cancer, and have proved fatal. It is essential in an investigation of this kind that no doubt should exist as to the nature of the disease; the reason for omission in the two cases was the inaccessibility of the growth and the danger of continued bleeding after the section had been taken.

### TREATMENT.

All the cases treated were advanced and inoperable, and many were in poor general condition. In the present state of our knowledge it does not seem fair to submit early cases to this method of treatment.

### Treatment of the Primary Growth.

A complete dental toilet was first carried out. Of the 29 cases, 5 had some preliminary treatment to the growth; in 2 a partial excision to remove sloughing tissue was performed. This in no sense of the term approximated to a surgical excision, but was rather of the nature of a wound toilet. It was later found that treatment of the ulcer by pure formalin gave a better result, the formalin acting as a caustic and leaving a clean ulcer after the sloughs had separated. This preliminary treatment was carried out in the remaining three cases.

In the majority of cases the radium needles were inserted under general anaesthesia administered by a catheter through the nose. In a few cases local anaesthesia or infiltration of the lingual nerves was employed, but this fails to give sufficient anaesthesia to allow of ease of manipulation of the tongue, jaw, and soft parts generally. The needles used were 5 mg. tubes screened with 0.5 mm. of platinum, but it is probable that tubes of smaller power would be preferable and less likely to cause radio-necrosis.

Some idea of the "mass" of the growth was first obtained by palpation, and the number of needles inserted varied with this. The needles, threaded with the strongest vaselined silk obtainable, were inserted deeply into the tissues at least 1 cm. from the growing edge. If the ulcer was very extensive two or three needles were placed beneath the floor of the ulcer parallel with its surface and at a depth of 2 or 3 cm. Special care must be taken to place the needles as far away from bone as possible. It is difficult to protect the bone sufficiently in cases where the floor of the mouth is involved, and in two cases some necrosis of the mandible followed treatment. Adequate protection of the alveolus by moulded lead sheeting has proved difficult owing to the close proximity of the ulcer to the bony alveolus in most cases of epithelioma of the floor of the mouth.

The needles were kept in position for forty-eight hours in most cases, but in a few they were left in for seventy-two hours. The number of tubes inserted varied with the size of the growth, but as these were large in most cases eight tubes was the average number used in the mouth. This represents an average dose of 1,920 mg. hours for the primary growth. In many cases a second and even a third dose was given.

Some degree of local reaction followed in most cases; this consisted in local swelling, superficial necrosis of the epithelium at the site of the needle punctures, and general reddening of the tissues around the irradiated zone. A very considerable degree of reaction occurred in 9 cases where a very extensive growth was treated, and probably the dose given was excessive. Radio-necrosis is a most troublesome complication, especially if bone is involved, and must be avoided by careful screening, guarding against overdose, and care in the position of the needles. In the early cases especially too massive doses have been administered.

### Treatment of the Glandular Fields.

Where the glands were enlarged but operable a block dissection of the neck was undertaken on one or both sides, depending on the site of the ulcer and the nature of the glandular enlargement. Radium needles were implanted in the wound, especial care being taken to place the tubes at such intervals that the whole field was irradiated. This procedure was employed in 9 cases. In the remaining 20 cases the glands were badly infected and quite inoperable in 18, and not infected so far as could be ascertained in 2. These 20 cases were treated by irradiation alone, needles being embedded in the tissues of the neck through a trocar. Ten to fifteen needles were used over a period of forty-eight to fifty-six hours. Most cases had two applications to the glands at intervals of three months, while a few had three or more. Where possible the irradiation of the primary growth and the neck was carried out concurrently.

### RESULTS AND REMARKS.

Of the 29 patients treated and kept under observation for two to three years, 10 (34.5 per cent.) died, 11 (38 per cent.) showed no improvement, and 8 (27.5 per cent.) had improved. Three of the deaths were due to intercurrent disease—cardiac failure, acute appendicitis, and perforated duodenal ulcer. In 9 of the 21 patients comprising those

who died and those who were not improved the primary growth had been apparently checked and healed, but the glandular deposits had continued to progress. Of the 8 cases definitely improved, one patient has been treated by irradiation alone and is apparently free from recurrence over a period of three years and four months; in 3 cases the ulcer has healed, no recurrence can be detected, and microscopical examination of the scars left shows no tumour cells present. In 4 cases healing of the ulcer has followed and the glandular deposits lessened in size in all, completely disappearing to palpation in 2.

There can be no doubt that the primary growth reacts better than do the glandular deposits; this is certainly due to the fact that an intensive cross-fire action can be more easily obtained. Small doses over a prolonged period of time are preferable to large doses acting for a short period. The 5 mg. tubes are probably too large a dose for very prolonged insertion, and a trial is to be made of less powerful needles. The best results are to be expected from growths of the tongue itself, and especially those of the anterior two-thirds; epitheliomata of the floor of the mouth and the pharyngeal portion of the tongue are especially difficult to treat on account of the difficulty of access and also of the danger of necrosis. The warty exuberant type of epithelioma gives a better result than the ulcerative type, which unfortunately is the more common. No anaemia, as shown by a series of blood counts and haemoglobin estimations, has followed even the most massive doses, nor has the cholesterol content of the blood been affected. The greatest care in regulation of the dose, screening, and placing of the needles is essential to prevent radio-necrosis.

It is possible that a combination of lead colloid and radium represents the ideal treatment, since the lead may help to check the glandular deposits while having less effect on the primary growth. An extensive recurrent growth treated on these lines improved considerably. It is to be noted that all the cases treated were past all surgical intervention, and it is probable that earlier cases would react much more favourably than the above figures indicate.

#### RECTAL CANCER.

The number of cases of rectal cancer admitted to the department was 33. Of these, 26 were suitable for radium therapy and 7 were unsuited (5 were hopelessly advanced and almost moribund; one was operable and the growth was excised; and one was treated by lead owing to liver deposits). Of the 26 patients, 22 were males and 4 females. The average age of the patients was 57. All were advanced and inoperable, in most cases there was extensive infiltration of surrounding structures, especially the bladder, prostate and perirectal cellular tissues.

Microscopical examination of tissue removed showed the presence of adenocarcinoma in 23. In the remaining 3 patients sections were not obtained owing to the inaccessibility of the growth. All these were clinically typical carcinoma, and in none of the three did any improvement occur under radium treatment.

#### TREATMENT.

All patients were advised to have a preliminary colostomy, for two reasons: first, to allow of exploration of the abdomen, as it is obvious that secondary deposits in liver or peritoneum prohibit any local treatment such as irradiation; and secondly, for the purpose of keeping the growth as clean as possible.

Needles of 5 mg. and occasionally of 10 mg., screened by 0.5 mm. of platinum, were used. In 5 cases the coccyx was excised to allow of implantation of the radium needles directly around a posterior growth. In 16 cases some needles were implanted deeply into the perirectal cellular tissues by puncture of the perineum and ano-coccygeal raphe with a trocar. This procedure requires rigid asepsis and constant dressing if it is not to be followed by perirectal suppuration. This occurred in two cases, resulting in fistulae which never healed. In all cases needles were implanted deeply into the growth from the rectal surface in addition to the two procedures mentioned previously.

Owing to the large mass of these advanced rectal growths and the necessity for getting an intensive cross-fire action a considerable number of needles are inserted, fifteen or twenty 5-mg. needles being required. The rectum tolerates

these large doses well if a preliminary colostomy has been performed and the tubes are not placed too closely together. It has been found advantageous to pack the bowel lumen with rubber tissue to keep the needles embedded in the growth well apart. This also helps to protect the intact mucosa below the growth from the effects of too close proximity to the needles, and also allows of the free discharge of blood and infected fluids from the surface of the growth.

In all, the 26 cases had forty-seven exposures, as follows:

- 1 had 4 exposures, totalling 15,300 mg. hours.
- 5 had 3 exposures, with an average of 14,626 mg. hours in each case.
- 8 had 2 exposures, with an average of 9,375 mg. hours in each case.
- 12 had 1 exposure, with an average of 4,180 mg. hours in each case (treatment is not complete in all these cases).

#### RESULTS AND REMARKS.

Of the 26 patients in this category, 13 are dead and were not improved in any way, 8 are alive but show no improvement, 5 (19 per cent.) are definitely improved. Of the 5 showing improvement, 2 were irradiated twice and given a total of 9,600 and 8,900 mg. hours respectively; 2 were irradiated on three occasions and given totals of 16,080 and 16,920 mg. hours; one was irradiated on four occasions and given a total of 15,300 mg. hours.

In two of these cases the improvement was most noticeable. In one case, where the growth was very low down and easily accessible, a very complete irradiation was possible from all angles. The growth entirely disappeared, leaving a fine pliable scar, sections of which failed to reveal any tumour cells. The second case was an exuberant warty adenocarcinoma; this also completely disappeared, leaving a fine scar. These two patients have been kept under observation for eighteen months and remain satisfactory. In the three remaining cases the improvement was slight but definite, the growths becoming smaller, harder, and more fibrous as compared with previous sections.

Cancer of the rectum is a much less favourable field for radium therapy than is the tongue. The reason for this is the difficulty of access and still more the intense septic element which, in spite of the most careful preparation of the patient, is almost inevitable. Further, it is difficult, indeed probably impossible, to reach the upper part of the glandular field with any extension of the surgery of access, the glands along the inferior mesenteric artery being quite out of reach. For any satisfactory result, then, the growth must be early, low down, and the glandular field but little involved.

I desire to acknowledge the help of my colleagues Dr. Lamb and Dr. Teall. Dr. Lamb has undertaken all the investigation of pathological material and has also investigated the blood before and after irradiation; Dr. Teall has been of great assistance with advice of a technical character. Without them this work could not have been carried out.

#### A CASE OF DUPLICATION OR SUBDIVISION OF THE TESTICLE.

BY

G. H. EDINGTON, D.Sc., C.M., F.R.F.P.S.GLAS.,  
VISITING SURGEON, WESTERN INFIRMARY, GLASGOW;

With Histological Note by

J. W. S. BLACKLOCK, M.B., CH.B.GLAS.,

LECTURER IN PATHOLOGICAL HISTOLOGY, UNIVERSITY OF GLASGOW.

DUPLICATION, real or supposed, of the testicle would seem always to have excited considerable interest in both lay and medical circles. There is no doubt that the condition must in early times have been presumed on very insufficient grounds; within recent years even the diagnosis has been made on a slender foundation. It seems a truism to state that authenticity can be established only by histological examination of the abnormal structure. It is now known that the condition does exist; but whether authentic or presumed it must be regarded as of very rare occurrence, and it is for this reason that the following example is recorded.

#### Clinical History.

The patient, a healthy youth aged 16 years, employed as a telegraph messenger, was sent into the Western Infirmary in March, 1924, with a swelling in the left scrotum. The swelling

was observed on physical examination for entrance to the Royal Navy, but its existence had been long known to the patient, and it had never caused him any trouble.

On examination the right testicle was felt in the scrotum, and apparently was normal. A smooth, rounded, mobile swelling the size of a marble was found in the scrotum above the left testicle. Elements of the cord were felt passing to it, and it was thought to be a displaced globus major, as the normal epididymis could not be demonstrated in the subjacent testicle. At operation the testicle and the abnormal swelling were found occupying a common tunica vaginalis. The lower body, regarded as testicle proper, was ovoid, and measured over 3 cm. in length by 2.3 cm. transversely, and 2.6 cm. antero-posteriorly. The upper body was globular, with a diameter of over 2 cm. It was freely mobile, and only indirectly attached to the lower by a pink strap-like structure several centimetres in length and 0.6 cm. across. The vas deferens was felt arising from near the lower pole of the testicle. The tunica vaginalis extended up along the spermatic cord to well within the inguinal canal, but it did not communicate with the abdominal cavity. The two bodies and intervening strap were covered by serosa on anterior and lateral aspects; the upper body was more completely invested and was pedunculated. The malformed organ being of doubtful utility the tunica and its contents were removed. Recovery was uneventful, and he was discharged on the twenty-first day.

#### Dissection of Testicle.

When the tunica was laid open and pinned out (Fig. 1) the upper body was seen to be attached to it posteriorly by a pedicle, a little over 2 cm. long, which passed upwards as a vascular plica extending to the upper end of the tunica. Seated on the lower part of this body was a small cup-like structure, 1.75 cm. by 0.75 cm., the expanded upper end of a strap, 4.5 cm. long, 0.6 cm. broad, and 0.4 cm. thick, resembling normal epididymis and passing down to lie behind the lower pole of the ovoid testicle. This strap was attached to the tunica vaginalis posteriorly by a fold like a mesorchium, measuring in its greatest breadth 1.2 cm., and incorporated medially with a vascular plica which extended up from the testicle. The latter body, the long axis of which was directed upwards and forwards, stood well out from the tunica vaginalis, to which it was attached posteriorly for about two-thirds of its length by a reflexion of serosa. From its upper pole a plica extended upwards medial to and blending with the pedicle of the upper body. Its postero-inferior pole showed a cup-like thickening, fully 1 cm. deep, which gave the testicle the appearance of an acorn. The lower end of the epididymal strap seemed to be spread out on the lower pole of the testicle, and from this pole the serosa was reflected in characteristic folds. Medially the serosa was smoothly reflected over the vas deferens and spermatic vessels; laterally it formed a deep gutter-shaped recess, about 2.5 cm. long, behind the lower part of the epididymal strap.

Further dissection (Fig. 2) showed that the epididymal strap passed down behind the testicle and bent sharply upwards and inwards to become the vas deferens. Vasa efferentia were present as stringy connexions between the strap and the lower pole of the testicle. The veins were arranged in two main groups: one from the upper body with addition of a convoluted vessel from the epididymis, the other from the testicle, forming a looped plexus.

#### Histological Report.

Dr. Blacklock examined portions of the testicle, of the strap, and of the upper body, and he reported as follows:

"*Lower Swelling.*—This is enclosed in a capsule composed of an outer layer of fibrous tissue in which are found numerous vessels, and an inner layer of non-striated muscle in which the vessels are less numerous. Inside these structures composing the capsule typical testicular tissue is present, and here and there evidence of spermatogenesis is found. Many of the gland spaces contain a mucoid secretion. The interstitial tissue and cells appear normal in character and in amount. In some of the sections small ducts corresponding to vasa efferentia are found between the testicle and epididymia.

"*Cord between Upper and Lower Swellings.*—This structure shows in its outer parts fibro-muscular tissue in which are present many small vessels (chiefly veins) and a few nerves. Its central part is composed of typical epididymis tubules lined by columnar ciliated epithelium, collections of spermatozoa being found in some of the lumina. Non-striated muscle is seen whorling around the ducts.

"*Upper Swelling.*—The part projecting furthest into the sac (tunica vaginalis) is composed of testicular tissue in all respects similar to that in the lower swelling, though the evidence of spermatogenesis is not so marked. This part is also surrounded by an outer fibrous layer and an inner non-striated muscular layer, which make it distinct from the outer part, which is composed of typical epididymis tubes. In the epididymis part typical ducts lined by columnar ciliated epithelium are present, and these are surrounded by whorls of non-striated muscular tissue in which are some fine vessels. Between the inner (testicular) and outer (epididymal) parts are found numerous fine ducts lined by a low columnar ciliated epithelium, and corresponding to the normal vasa efferentia."

#### LITERATURE OF SUPERNUMERARY TESTICLE.

Before commenting on the findings in the above case

I would like to refer briefly to the literature of supernumerary testicle. There is so wide a diversity in the cases published that a consideration of the literature entails a classification of the papers into different groups, ranging from generalizations to the more precise investigations of more recent years.

A. *General.*—Lucas-Championnière, in a clinical lecture delivered at the Hôtel-Dieu, reviewed briefly the subject of numerical anomalies from legendary to scientific times. He found that in proportion as exact scientific observations came to be made the numbers of cases reported tended to diminish. He referred to the legendary belief in the superfluity of individuals thus endowed. In 1911, some eleven years after the publication of this lecture, Conzette<sup>2</sup> wrote on the subject. He referred to Cruveilhier and Sappey

FIG. 2.—Parts viewed from medial side, with tunica vaginalis dissected to show vas deferens and blood vessels. a, vas deferens; b, strap-like epididymis.

FIG. 1.—Parts removed, viewed from lateral side with tunica vaginalis laid open. a, Spermatic cord; b, upper testicular body; c, strap-like epididymis; d, lower testicular body.

not having met with a case in fifty years, expressed his opinion as to the rarity of its occurrence, and then went on to discourse upon legendary supervirility, to which, however, he seemed disposed to give credence.

B. *Pseudo-duplication.*—Marsh<sup>2</sup> republished in 1911 a case (originally published in 1898) of a boy, aged 3 years, on whom he had operated for congenital inguinal hernia on the left side. At operation two testicles in a common tunica vaginalis were found in the scrotum. The child died after operation, and *post-mortem* dissection showed one vesicula seminalis, situated on the left side, and larger than normal. From it passed a very thick vas to about half an inch from the internal ring, where it divided. The two branches passed down the inguinal canal into the scrotum; one to each testis. The right spermatic artery arose normally, but crossed the middle line and joined the left at the internal ring to form a single vessel, which divided again into two before reaching the external ring, and passed one to each testicle. The condition seems comparable with Lowe's<sup>3</sup> case. In that case there was no *post-mortem* examination, and it was considered by the Editor of the *British Medical Journal* as an example of true dichotomy of left with non-descent of right testicle. Banks<sup>4</sup> has recently reported a case similar in some respects. He terms the condition "transverse ectopia" of the right testicle down the left inguinal canal; and Keith, who had an opportunity of examining the specimen, considered it the result of fusion and persistence of the Müllerian ducts. Banks gives four references to cases recorded by other observers.

C. *External Examination without Operation.*—A certain number of observers have recorded cases on the strength of external examination only. Davis,<sup>5</sup> in 1895, reported a case with three testicles in the left and one in the right scrotum. All were apparently perfect, with sensibility to pressure. Tomory<sup>7</sup> described (1898) the case of a boy, aged 3½ years, with both testicles in the scrotum, and in addition a rounded insensitive body in the left inguinal canal; the body was larger than a testicle. Fischer,<sup>8</sup> in 1916, recorded a freely movable swelling in the region of the right external ring. It was possessed of testicular sensibility, and

could be pulled down into the scrotum, with a corresponding movement in the normally situated testicle. The subject was 65 years of age, and the scrotum contained two apparently normal testes. Dar<sup>9</sup> reported, in 1918, a case in which there were five alleged testicles in the scrotum, and he reproduced a photograph of the parts. In 1921 Ayer<sup>10</sup> published clinical details of a case of supernumerary body above the left testicle. Testicular sensibility was present, both globus major and globus minor were felt, and a distinct cord traced alongside of the normal as far as the internal ring. A photograph shows the body on the left of the peno-scrotal junction, and of smaller size than the normally situated testicle below.

**D. Demonstrated by Operation: No Histological Examination.**—Turner,<sup>11</sup> in 1900, recorded the case of a child aged 34 years. On the right side there was an encysted hydrocele of the cord; further down a supernumerary testicle with cord, which blended above with the spermatic cord; and lowest of all the testicle proper with hydrocele of its tunica vaginalis. In 1910 DeFranceschi<sup>12</sup> reported a case of triorchismus in a youth aged 18 years. The supernumerary body lay in the upper part of the left inguinal canal, and its cord blended with that of the normal testicle. The body was removed and showed naked-eye characters of testicular tissue, but it was mislaid before histological examination could be made. Widhalm's case<sup>13</sup> differed from the above. He reported, in 1911, a case of left-sided double testicle, the right testicle being apparently normal. On the left side were: (1) omentocoele, (2) two cysts of the cord, and (3) hydrocele of the tunica vaginalis. On opening the tunica vaginalis two testicles were found side by side, having a common epididymis and two vasa deferentia. Coudert and Deroque,<sup>14</sup> in 1924, reported an operation on a supposed strangulated left inguinal hernia in an infant aged 7 months. A violet-tinted tumour appeared, resembling strangulated testicle. The cord was dissected and showed two elements, one passing to the strangulated testicle and the other to the normal gland lower down. The supernumerary body, which was strangulated by torsion of its pedicle, was removed. It showed complete macroscopic appearances of a testicle. Histology was not completed at the time of publication (nor has it yet appeared, August, 1927).

**E. Operation and Histological Examination.**—While the demonstration by operation is a step forward towards establishing the nature of unusual scrotal contents, the authenticity of supernumerary testicle rests on histological examination. Judged by this standard I have found in the literature only eight cases which emerge satisfactorily from the test. In chronological order they are as follows:

(1) 1897. Lane.<sup>15</sup> Youth, aged 17. Cherry-sized body situated above right testicle, and suspended from spermatic cord by a pedicle. Supernumerary body removed and showed microscopically tubules in which spermatogenesis was present.

(2) 1899. Lössen<sup>16</sup> (quoted by Haas, *infra*). In right-sided hydrocele sac of man, aged 28, two bodies, one above the other, each with appearance of testicle and epididymis. Cord showing epididymal tubules united the epididymes. Single vas deferens passed off from lower pole of lower epididymis. Both testicles showed spermatogenesis.

(3) 1907. Mariotti.<sup>17</sup> In patient, aged 28, with ostensibly a large left inguinal hernia, two cords were found after opening inguinal canal. The larger cord passed to a normal epididymis, the smaller ended in a bean-sized swelling which, after removal, showed normal reddish testicular tissue supported by fibrous tissue radiating from the tunica albuginea. The fibrous tissue appeared under the microscope to be rich in cells and free from fibroblasts. (Original paper not available; above details from *Zentralbl. f. Chir.*)

(4) 1910. Lerat.<sup>18</sup> Small, nut-sized, ovoid swelling, mobile, in left inguinal canal of a boy, aged 15 years, in whose scrotum were two normally placed testicles, identical in size. The swelling was diagnosed as cyst of cord; but operation showed it to be a testicle in an open processus vaginalis, and attached by epididymis to normal spermatic cord, which traced down to normal testicle, with its own tunica vaginalis. Examination of supernumerary body showed seminiferous tubules, without spermatozooids in tubules or canal of epididymis.

(5) 1922. Haas.<sup>19</sup> In a boy, aged 9 years, with double inguinal hernia, both testicles were in respective inguinal canals. In left canal there was, in addition, a pea-like body with vas deferens distinct from that of testicle proper. Histological examination showed highly atrophic testicle and widely open epididymis. Spermatogenesis is not mentioned, and was presumably absent.

(6) 1923. Jeannin and Delater.<sup>20</sup> Left inguinal hernia and painless cyst of cord, in man aged 21 years. Both testicles in scrotum, left smaller than right. Operation showed supposed cyst to be solid, and having consistence and colour of a testicle. Epididymis and vas not identified. Histologically tissue was testicular, with active spermatogenesis.

(7) 1924. Lecène.<sup>21</sup> Patient, aged 23 years, with congenital right inguinal hernia, and with two normal well-developed testicles in scrotum. On opening hernial sac a body, size of small olive, found hanging by a slender cord from the spermatic cord 5 or 6 cm. above the testicle. Thought to be subserous lipoma; afterwards found to be a small testicle resembling an ectopic organ. Histological examination showed testicular tissue without spermatogenesis.

(8) 1925. Holder.<sup>22</sup> Patient, aged 45 years, with two normal testicles in scrotum, had acute gangrenous process in left groin. Supposed inguinal lymph gland excised and found microscopically

to be testicular tissue, with epididymis and vas deferens, and showing active spermatogenesis.

**F. Abdominal Supernumerary Testicle.**—Oudendal's case,<sup>23</sup> reported in 1922, though hardly coming within the scope of the present paper, is of interest, and may be briefly referred to. It was accidentally discovered during *post-mortem* examination on a subject, age not given, whose external genitals were apparently normal. Within the abdomen was a third testicle, depending by a stalk from the ileum about 30 cm. above the ileo-caecal valve. The body measured 18 by 21 mm., and showed the histological characters of testicular tissue. There was no vas deferens, and spermatogenesis was not observed. The accidental observation of supernumerary testicle in the abdomen was later noted by Nieberle<sup>24</sup> in the case of a gelded pig, aged about 9 months, in which nodules were scattered widely over the parietal and visceral peritoneum. Some of the larger nodules were in the mesentery of the large bowel, others were irregularly distributed. Microscopically the nodules showed the characters of testicular tissue, without spermatogenesis.

#### Remarks on the Literature.

If we confine ourselves to Class E, in which the diagnosis was confirmed by histological examination, we find only 8 cases. Of these, 5 occurred on the left and 3 on the right side. In only 4 was spermatogenesis found; it was absent in 3, and in 1 its occurrence was doubtful. As regards the type of malformation, the pedicle or cord of the supernumerary organ sprang from the spermatic cord in 3 (Lane, Lerat, Lecène); it was presumably attached to the spermatic cord in 2 (Mariotti, Haas); in 1 there was a spread-out epididymis (Lössen); and in 2 the epididymis and vas were not identified.

The occurrence of abdominal supernumerary testicle does not seem to be of clinical interest generally. It is only likely to come under notice if it be the seat of inflammation or neoplasm, and should be kept in mind as a possible finding in the course of a laparotomy.

In addition to the observation by Nieberle (*supra*) in the pig, mention should be made of Gerhartz's<sup>25</sup> two examples in frogs. In one the accessory organ discharged its secretion through the duct of the main gland; in the other the accessory had no connexion with the main organ, although the development of the sperm had reached the same stage.

As regards Class D, it is recognized that in some cases the diagnosis cannot be more than presumptive. Presumption may be strengthened by a study of the records of specimens whose authenticity has been proved by histological examination.

#### Summary.

The specimen here recorded is an example of duplication of the body of the testis. It is to be regarded as an abnormal subdivision or duplication of that part of the intermediate cell mass which gives origin to the body of the testicle. The Wolffian duct has apparently developed normally to form the vas deferens and epididymis, and the epididymis is elongated so as to serve the two separate masses of testicular tissue. Both masses show spermatogenesis—a noteworthy finding, since in a number of cases of duplication the supernumerary organ has been found defective in that respect, a condition of affairs comparable with what often occurs in ectopic testis. The specimen would seem to be similar to that of Lössen (*vide supra*), and one of the less frequent varieties.

## THE DIAGNOSIS OF BRANCHIAL CYST;

WITH A NOTE UPON ITS REMOVAL.

BY

HAMILTON BAILEY, F.R.C.S.Eng.,

GILLSON SCHOLAR, SOCIETY OF APOTHECARIES; SURGEON, DUDLEY ROAD  
HOSPITAL, BIRMINGHAM.

It is common to find a branchial cyst mistaken for breaking-down tuberculous cervical glands. Eleven cases have come under my observation where this error had been made, and in not a few of these treatment for tuberculosis had been persisted in.

Branchial fluid, on being aspirated, looks just like tuber-

FIG. 1.—Typical branchial cyst. Note relationship to upper third of the sternomastoid.

culous pus, a coincidence which, combined with an implicit trust in the bacteriological report, is the fundamental basis of this confusion.

"No tubercle bacilli found; cultures sterile." We have rightly come to look upon this familiar report as confirmatory evidence of tubercle. But it should be borne in mind that branchial fluid is also often sterile.

In about 10 per cent. of cases tubercle bacilli are found in tuberculous pus. In such cases it would appear ridiculous to suggest the possibility of an alternative diagnosis. The following exceptional case proves the contrary. A branchial cyst was removed by operation, and its wall, subjected to histological examination, revealed stratified squamous epithelium upon a basis of lymphoid tissue. The fluid aspirated before operation, and the contents of the specimen after operation, showed numerous tubercle bacilli. Doubtless organisms can penetrate the epithelial envelope from its ensheathing lymphoid covering, which in turn is connected up with the cervical lymphatic system.

Breaking-down tuberculous glands are exceedingly common. Branchial cyst is comparatively rare. The difficulties which surround the diagnosis of the latter are admittedly formidable, but they are by no means insurmountable.

*Clinical Features.*

Branchial cyst usually makes its first appearance in early adult life. The onset is often curiously abrupt, after which the cyst begins slowly to increase in size. Recurrent attacks of inflammation in the cyst are usual.

Branchial cyst is nearly always related to the upper third

of the sterno-mastoid (Fig. 1). It is usually found coming from the deeper planes of the neck around the anterior border of this muscle.<sup>1</sup> But as the sterno-mastoid is thinned and flattened over the cyst this relationship is seldom clear until the muscle has been rendered taut.

If a swelling answering to the above description is found the absence of enlargement of the cervical glands when the neck is systematically palpated should raise in the examiner's mind the question, "Is this a branchial cyst?" This question can be promptly settled by the following simple confirmatory test.

*Confirmatory Test for Branchial Cyst.*

After the skin has been sterilized a little of the fluid

FIG. 2.—The cyst has been rendered flaccid by aspiration of half its contents, which considerably facilitates total enucleation.

is aspirated. It will usually run quite easily through a needle of an ordinary hypodermic syringe. A drop of the aspirated fluid is placed upon a slide, and covered with a cover-slip. The slide is then examined under the microscope with a one-sixth power lens. The presence of numerous cholesterol crystals at once makes the diagnosis certain. Fig. 3 is a photomicrograph of a drop of fluid removed from a branchial cyst for the purpose of confirming the diagnosis.

FIG. 3.—Photomicrograph of branchial fluid. The abundance of cholesterol crystals is characteristic.

*Removal of a Branchial Cyst.*

A branchial cyst should be completely removed by dissection. It may be conveniently exposed by a transverse incision following the line of the creases of the neck. Except in small, superficially placed cysts it will be found best to divide the sterno-mastoid. Beneath this muscle the spinal accessory nerve will be found bearing a constant relationship to the cyst wall. The nerve should be isolated.

Branchial cysts often run deeply into the neck, and may extend upwards as far as the base of the skull. In this respect they resemble an iceberg, for the greater bulk of the mass is beneath the surface. It is most desirable to remove the cyst intact. If the cyst bursts halfway through the operation dissection is

rendered difficult, surrounding structures become endangered, and the end-result may prove unsatisfactory, for even a small piece of secreting epithelium left behind may give rise to a sinus which persistently discharges. Complete dissection of an intact cyst is almost always possible, and the operation is very much simplified if the following technique is adopted.

After carefully cleaning the superficial aspect about half the contents of the cyst are removed by aspiration. The

puncture hole thus made is covered with a piece of gauze about the size of two postage stamps. The gauze and the cyst wall are then picked up with a pair of sponge-holding forceps (Fig. 2). The gauze minimizes leakage and prevents the forceps slipping. Gentle traction may be made with the forceps at first in this direction and then in that, and the cyst wall is cleared by gauze and blunt dissection, aided here and there by a few touches of the scalpel. As dissection proceeds and the deep parts of the cyst are reached it will be found convenient to apply a second pair of sponge-holding forceps. Using these means the intact cyst may be completely enucleated.

## TONSIL-SUCTION FOR DIAGNOSIS AND TREATMENT.

BY

FRANK C. EVE, M.D. CANTAB., F.R.C.P. LOND.,  
SENIOR CONSULTING PHYSICIAN, ROYAL INFIRMARY, HULL.

### INSTRUCTIONS FOR USE.

#### In Diagnosis.

The patient sits facing a good light and removes dentures. The diagnostic tonsil-sucker is warmed in hot water to prevent condensation. With the stem against the angle of the mouth the sucker is pressed firmly against the opposite

tonsil, the suction ball is well squeezed, and then released with the finger over the air-hole on the stem. The tonsil is thus extroverted, and any pus in its crypts is seen—yellow on the red tonsil—inside the glass funnel. The glass funnel is now given a combined pull and a slide towards the cheek, so that the pus is picked off by the incurved glass edge; excessive suction will prevent the sliding movement. This needs a little knack. Repeat to ensure that all pus is removed.

The pus can be microscoped (for polymorphs and germs), and the patient is requested to see it and smell it (it is usually offensive) in the funnel to convince that treatment is necessary.

#### The Therapeutic Tonsil-sucker.

This glass funnel is similar to the diagnostic one, but has a wider mouth, thicker rim, and its edge is not

incurved. A rubber finger-stall (medium thickness) is wetted and slipped over the glass funnel. It should form a flat diaphragm across the funnel mouth. On this the antiseptic cream is thickly spread. This is pressed against the tonsil and strong suction applied. The crypts of the extroverted tonsil are thus thickly smeared with the antiseptic cream. Pressure is then relaxed (by opening the vent-hole); the tonsil subsides into its usual shape, carrying the antiseptic into the crypts and spaces from which the pus has been evacuated. This manoeuvre should be repeated thrice in rapid succession before withdrawal.

After use the glass funnels should be cleaned and kept in the glass jar of weak carbolic provided. The rubber ball acts as stopper to the jar. The finger-stalls can also be cleaned and kept in this solution, and used again. For more rapid sterilization I use a saucepan.

The antiseptic cream contains mercury oleate, bismuth, kerosene (for its creeping qualities), and vanishing cream. Better formulae are being searched for.

As an extra safeguard, the portion of the glass tube which enters the patient's mouth is enclosed in a sleeve of rubber tubing.

Treatment is repeated at least once a week until no more pus is found. Then the interval can be lengthened to 10, 14, 21, or 28 days. The course is usually longer in older patients than in younger, though the health may be benefited long before the pus is all gone. Tiredness, pallor, anorexia, rheumatism, and other subinfective toxic symptoms often quickly disappear. In quinsy and acute tonsillitis it will probably be found that septic fluid can be sucked out and tension relieved with a larger glass funnel having a layer of cambric tied flat across its mouth.

### Illustrative Cases.

#### CASE I.

Dr. N., aged 35. Had bad tonsillitis after sleeping in a damp bed in 1919.

Tonsillitis recurred with rheumatic pain and swelling in ankles, finger-joints, and back in March, 1927. I saw him first five months later; the fingers and ankles were still swollen, with flat feet. Though the tonsils looked normal I could suck liquid pus out of them having the same smell as the nasty taste he was getting. This pus was largely composed of polymorphs, with only a few pneumococci, bacilli, and diplococci.

At first I cleaned the tonsils twice a week by suction, later weekly, then monthly, and left various antiseptics in the crypts—for example, thymol iodide and kerosene, bipp, iodoform and kerosene, and ung. hydrarg. molle. The amount of pus rapidly diminished, and in about two months there was little or none. His rheumatism also quickly diminished, and he was able to do his practice throughout.

On December 20th he reported himself as very well and without rheumatism; the tonsils contained no pus and remain free (May 2nd). He can taste iodoform when he drinks anything hot eight hours after treatment, proving that the antiseptic is buried in the crypts. He thinks this diagnostic and therapeutic method has a great future.

#### CASE II.

Miss M., aged 32. Had poor health with frequent colds, sore throats, and abdominal pains and occasional rheumatism. In November, 1925, beads of cheesy pus were sucked from both tonsils. On December 20th there was no pus. In December, 1926, two beads of pus were found in the left tonsil. In April, 1927, she could squeeze beads of foul pus from her tonsils and could feel it accumulating. In May I started treating the tonsils by suction with euthymol and aristol. In July (eight treatments) her rheumatism had gone and the tonsils were almost clear of pus, but her adenoids were still sore and dirty. In September she had to have her adenoids out, and obviously this opportunity of removing the tonsils had to be taken, though they were clear of pus both by suction and in microscopic section.

#### CASE III.

Mrs. A., aged 57, had suffered from rheumatic neuritis in the left arm for three years. Had "always" had rheumatism in the hands and ankles, and frequent pain and swelling in the tonsillar glands. Had quinsies twenty years ago, and all teeth extracted ten years ago. Her father was crippled with rheumatism for twenty years. Pus was sucked from the tonsils. Suction treatment was started on June 22nd (menthol, aristol, calomel, glycerin). After nine treatments (September 2nd) there was no pus in the left tonsil and the glands had ceased to swell. She looked well, but was still rheumatic.

Between September 27th and October 11th she was given three injections of contramine. On October 18th the pus in the right tonsil was nearly all epithelial debris; there were no polymorphs. On November 1st the rheumatism was wonderfully easier, and on November 29th there was no pus in either right or left tonsil.

On January 3rd, 1928, friends remarked on the wonderful change

in her condition. On January 29th she had mild cholecystitis, which soon yielded to hexamine. There was a little pus on the right tonsil and slight rheumatism in the left shoulder, but nothing like it used to be.

The chronic ill health and rheumatism of this patient was certainly very greatly improved *pari passu* with improvement in the tonsils.

#### CASE IV.

Miss P., aged 23. This patient had chronic appendicitis. Pus was cleared from her tonsils in seven treatments during two months without influencing the kinked appendix, which was excised as soon as it was convicted. After an untreated interval of three and a half months the tonsils were still clear of pus.

#### CASE V.

Miss H., aged 25, was a keen athlete, but now too tired, even in the morning, for anything. She had tuberculous dacrylitis as a child. There was offensive pus in both tonsils. I thought her tiredness was due to septic absorption, presumably from the tonsils. The pus contained few polymorphs; no pathogenic germs were recognized. On November 26th treatment by tonsil-suction (iodoform, bismuth, and kerosene) was started. After much rest and five treatments she was much better and could skate; there was still slight pus in the right tonsil. On February 1st the tonsils were clean. Ten days later there was a little pus, but her health was better than it had been for six months. On March 30th she said she was "never tired"; there was very slight pus in the right tonsil.

Besides rest, this patient had no other treatment except (later) ultra-violet rays and arsenic, so that it looks as if her ill health had been due to septic tonsils.

#### CASE VI.

A woman, aged 50, with seven months' constant asthma, which promptly vanished with one cleaning of the tonsils, and the pus almost cleared up in three treatments.

Two other severe and very chronic asthmatics (complicated) also not benefited (so far).

#### CONCLUSIONS (PROVISIONAL).

Although pus may be demonstrated by this method in many young adults in good health, yet it can hardly be doubted that, when they get older—to the fibrositis age—and less resistant, the infection will accumulate and conquer their resistance, and they will get rheumatism in some form.

I have been using tonsil-suction diagnostically for three years, and should estimate that in patients with fibrositis pus can thus be demonstrated in their tonsils in 90 to 95 per cent. of cases, acting as a focus of subinfection. The tonsils may look quite normal and yet contain pus. The ordinary method of expressing pus with a spatula may be far more painful; one patient said it was agonizing, whereas my method was merely unpleasant. It is a more searching method, and the pus can be seen (and smelt) by the patient. That is an important advantage. If there are infected teeth or sinuses these should first be put right, as the tonsils may then clear themselves.

The method needs trying on a much larger scale and bacteriologically. I have been almost limited to private patients in a consulting practice; so that in these six patients alone has the treatment had a proper trial, except in one lady of 57, where the issue was confused.

In the septic tonsils of adults, the risk of serious hæmorrhage after tonsillectomy should be minimized by a preliminary course of tonsil cleaning by suction.

The method is at any rate quite harmless; two of my cases indicate the importance of cleaning the tonsils after a quinsy (or tonsillitis?) and seeing that they remain clean. Six to twelve treatments have usually cleared the tonsils of pus.

My plan is to make the intervals longer as soon as pus ceases to be found; but I cannot yet say whether a few treatments annually will be necessary to keep the tonsils free from pus. Perhaps better pastes will be more effective. Evidently tonsillectomy is the best cure when possible and safe; but in adults it is practically a major operation, and in many patients it is out of the question. Painting tonsils containing deep pus is evidently fatuous. Hence an alternative is most desirable, and seems to be provided by this method, which is available to the general practitioner.

The glass funnels are much more subtle than they look—like golf clubs—and I have had to stand long over the very skilful glass-blower to get them right. Messrs. Roynolds and Branson, Leeds, are the makers.

## INTRATRACHEAL INHALATION AND INSUFFLATION OF CHLOROFORM BY MEANS OF A FLEXIBLE METAL CATHETER.

BY

W. DAKIN MART, B.A.CANTAB., M.R.C.S., L.R.C.P.,  
SENIOR ANAESTHETIST AND LECTURER ON ANAESTHETICS, THE ROYAL INFIRMARY, SHEFFIELD.

Some fifteen years ago I wrote a paper on the intratracheal insufflation of chloroform by means of a gum-elastic catheter. This catheter did not last long, and had to be continually replaced. For some time now, however, Mr. W. S. Kerr, honorary surgeon to the nose, ear, and throat department of the Royal Infirmary, Sheffield, and I have used, instead of the gum-elastic catheter, one made for the most part of flexible metal, and this has given every satisfaction to both the surgeon and the anaesthetist.

The method of administration differs somewhat from the old procedure. The instruments used include a flexible metal catheter, an adapter, a Junker's apparatus, complete with tubes and bellows, and an anaesthetic mask for induction.

The flexible metal catheter is made by Mayer and Phelps in two sizes, No. 12 and No. 16; it is rigid at either end for about two inches, the remaining part being flexible. (See figure.) The internal non-flexible part has an opening at the side, in addition to the end opening. The external non-flexible part, which during action is wholly outside the mouth, is a copy of the internal, except that the external end is somewhat funnel-shaped. The openings at the side are of the same lumen as the catheter, or possibly slightly larger. A blunt metal stylet is provided, the length of which is less than the length of the catheter; this provides rigidity to the catheter during introduction.

The metal adapter (see figure) is made to fit into the funnel-shaped end of the catheter by one end, whilst the other end is attached to the rubber exit tube of the Junker apparatus. The lumen of the adapter is either No. 12 or No. 16 catheter size, according to which size is in use. One Junker's apparatus has all its tubes No. 12 catheter size, and the other all its tubes No. 16 catheter size, for employment with the appropriate size of catheter.

The following method is adopted to induce and maintain anaesthesia.

Preliminary medication is by means of morphine and atropine, which should be injected at least half an hour before induction is commenced. Anaesthesia is induced by means of chloroform dropped on to a mask; this should be fairly deep, because otherwise the patient may come round during the introduction of the catheter into the trachea. When the patient is fully anaesthetized the catheter is at once introduced into the trachea with the aid of a bronchoscope, the stylet being within the catheter.

The catheter having been introduced through the vocal cords, the stylet is at once withdrawn and the catheter attached, by means of the adapter, to the rubber exit tube of the Junker apparatus. There may be some coughing at this stage if the patient has not been sufficiently anaesthetized, but this can soon be remedied by placing the finger over the hole in the rigid portion of the catheter outside the mouth and pumping chloroform vapour into the lungs by means of the bellows of the Junker apparatus. I usually at this stage give three pumps with the bellows, while my finger is over the hole, and then remove my finger so that the patient may have a breath of air, and repeat this procedure until the patient is again completely anaesthetized. I do not think there is any danger, at this stage, to the alveoli from excess pressure by this pumping, as there is plenty of room outside the catheter in the trachea to act as a safety valve.

The surgeon now completely plugs the throat around the

catheter with sponges, so that the alveoli now get the full effect of any excess pressure from the bellows, which must be used, therefore, very lightly. In practice it will be found that as soon as the sponges have been placed in position the pumping of chloroform vapour into the lungs is no longer necessary, as the patient will draw chloroform vapour through the Junker apparatus on inspiration, when the finger is placed over the external hole in the catheter. I therefore remove the bellows from the Junker apparatus, and the patient inspires chloroform or air as desired by the anaesthetist. The anaesthetist must never forget that he now has that which the patient breathes absolutely under his control, just as is the case in the administration of nitrous oxide and oxygen. He has therefore to find out the ratio of air to chloroform vapour required by each patient to keep them in a satisfactory stage of maintenance.

I usually start, when the stage of maintenance has been reached, with three inspirations of chloroform vapour inhaled by the patient through the Junker apparatus to one inspiration of air inhaled through the side opening in the catheter outside the mouth; in other words, the finger is placed over the side opening in the catheter while the patient takes three inspirations of chloroform vapour, and the finger is taken away from the opening whilst the patient takes one inspiration of air. What actually happens when the finger is taken away from the opening, after the three inspirations of chloroform vapour, is that an expiration is the immediate result, followed by an inspiration of air, then another expiration through the opening, and then the finger is again placed over it to permit the three inspirations of chloroform vapour, and so on. This I find is the average ratio of chloroform to air which suffices to keep a patient in the stage of maintenance and in a good condition. Some patients, however, require more air to keep their blood a good colour than others, and, on the other hand, there are some who require a

bigger proportion of chloroform vapour to air to keep them fully anaesthetized. The deeper the anaesthesia the lighter the breathing, and the lighter the anaesthesia the deeper the breathing during the stage of maintenance.

The anaesthetist should keep a constant watch on his Junker bottle, in order that he may note the force with which the chloroform vapour is drawn through. This is a most excellent index of the force and depth of the patient's inspirations. Should the bubbling of vapour through the Junker become light I invariably take this as an indication that the patient requires more air, and accordingly see that he has it.

The advantages of this method are:

1. The maintenance of a perfectly clear airway.
2. The prevention of blood entering the air passages owing to the complete plugging of the throat around the catheter.
3. The absolute control of the amount of anaesthetic inhaled by the patient.
4. The patient inhales at each inspiration, by his own efforts, the amount of anaesthetic or air which the anaesthetist thinks he requires. Pumping by means of the Junker bellows is dispensed with.

This variety of anaesthesia is undoubtedly the best method to adopt in all operations on the upper jaw or nose, and I have not the slightest doubt that anaesthetists who use it will be pleased with the result.

Mr. W. S. Kerr, at whose suggestion the flexible metal catheter was made, and at whose request I have written this paper, is very well satisfied with the results from the surgeon's point of view. My thanks are due to him for suggestions given to me in compiling this paper, and also to Messrs. Mayer and Phelps for making the catheter and adapter.

### MEDICAL, SURGICAL, OBSTETRICAL.

#### CONGENITAL HEART-BLOCK.

The occurrence of two cases of congenital heart-block in one family is so unusual as to deserve being placed on record.

A married woman, aged 21, was delivered of her first child, a female, in 1922. This child has been under my observation since birth; her ventricular heart rate has varied from 40 to 60 beats a minute, and the pulse has always been regular in force and rhythm. During the first few years of life the child lacked energy, and was cyanosed at times, particularly in cold weather; she walked slowly, refused to be hurried, never ran, and was quite content to lie still for long periods. This state of affairs gradually disappeared, and now, at the age of 6, she appears to the casual observer as an ordinary healthy child, able to run about and up hills with no more distress than the average child. There is now no cyanosis. The ventricular heart beat when last noted was 42, and regular in force and rhythm. The cardiac dullness is increased to the left, and the apex beat is in the fifth space, one inch outside the mid-clavicular line. On walking up and down stairs three times the ventricular beat remained regular and did not alter; there was no apparent increase in the cardiac dullness, and the only effect of this exertion was a slight temporary increase in the respiratory rate. The systolic blood pressure is now 115 mm. Hg; I have not been able yet to determine the diastolic pressure in this child owing to the small size of the arteries at her age.

The heart has apparently accommodated for its slow beat by an increase in size and force of beat sufficient for the present for all ordinary purposes, but it would appear wise to conserve energy by avoiding as far as possible undue stress.

Subsequent to the birth of this child two normal boys were born, each at an interval of two years. In March, when examining the mother, who was eight months pregnant, I noted the foetal heart rate was 39; at subsequent examinations the rate varied between 40 and 60. A female infant was born normally on March 17th. Immediately after birth the pulsation of the cord was 63 and slightly irregular, with occasional forcible beats; this soon steadied to a regular even rate of 48. The baby cried strongly; its weight at birth was 7 lb. There are at present no murmurs, no evident enlargement of the heart, and no cyanosis, but the mother states that there were frequent attacks of blueness during the first fortnight. At the age of 1 month the baby is doing well and appears normal, except for the ventricular heart rate. There have been no miscarriages. The mother suffers from

Mikulicz's disease—a chronic swelling of the parotid glands with occasional severe attacks of swelling of all the salivary glands, for no particular reason, but so severe as to need morphine for the relief of the pain. She is slightly deaf as the result of middle-ear disease in childhood, but is otherwise healthy. The father is normal, except for the loss of a leg, the result of war wounds. There is no history or evidence of any venereal disease, and no history of heart trouble among the relations.

Apparently the development of congenital heart-block, or perhaps the failure to develop normal conductivity, is developmental in origin, and it is pure coincidence that two cases of such a rare disease as congenital heart-block have occurred in the same family.

Tunbridge Wells.

#### A CASE OF SOMATIC TAENIASIS.

DR. ROBERT HUTCHISON, on March 3rd, 1928 (p. 335), warned us against diagnosing rarities, but they do sometimes occur, as is shown by the following report of a case of generalized tapeworm infection.

A strong young man became an invalid, his first complaint being severe headache. Malaria was thought of and eliminated, but early pernicious anaemia was considered possible. The patient then said that his fingers and thumbs tingled, and pains ran down his legs; he staggered when he walked. As there was nothing to account for his symptoms he was thought to be malingering, but he then became really ill. His left leg swelled and his temperature rose, but after a few days he recovered. He commenced work, but shortly afterwards had a fit. These fits recurred and were thought to be hysterical, but I doubted this etiology. His speech became hesitating. He looked at times an invalid, but at other times I saw him walking briskly and normally. He then brought to my notice some lumps under his skin, which were tender and about the size of a large pea. I thought that these lumps might clear up the mystery of his disease. I was asked to certify him as insane, but at my examination I discovered he had double vision, and so I decided that the case was physical, not mental, and this despite the fact that he had auditory hallucinations. At length a lump was excised, and examined. The pathologist reported that it was a cyst containing larval worms, probably the cysticercus stage of pork tapeworms.

Thus the mystery was solved; it was a case of visceral cestodes. The rarity of this condition is mentioned in the article on diseases caused by cestodes in Osler's *Textbook*

of Medicine. The diagnostic difficulty was considerable; in one of his "fits" the patient presented the appearance of a case of acute heart failure. Had a lump been examined in 1922, when the patient was in the army, there would never have been any mystery. Probably they were taken for fatty tumours, which, I am told, are sometimes tender.

Kilnhurst, near Rotherham.

C. J. HILL AITKEN, M.D.

## PROFUSE HAEMATEMESIS SECONDARY TO AORTIC AND MITRAL INCOMPETENCE.

THE case here recorded is, I think, of sufficient interest to warrant publication.

I was called one evening to a boy, aged 16, whom I found rather collapsed. Beside the bed was a pail containing about eight ounces of dark clotted blood. The haematemesis, I was told, had followed exertion; the patient had attempted to push a tram of coal, and immediately felt faint, and later began to vomit blood. He complained of little pain. He had never previously complained of epigastric pain, and had never suffered from discomfort or vomiting after food. I had treated him for aortic and mitral disease, following rheumatic fever. There was no history of haemophilia.

The temperature was 98° F. and the pulse (100) of Corrigan type. Epigastric pulsation was marked. There was no marked tenderness or rigidity in the epigastrium, and no tenderness anywhere. The lungs were clear. The heart apex was in the sixth interspace in the nipple line. A mitral systolic murmur, conducted to the axilla, was heard, and also an aortic diastolic in the second right interspace; it was conducted down, and was heard loudest in the mid-line in the fourth interspace.

During the examination the patient had another attack of vomiting, consisting of dark clotted blood and mucus, amounting to about a pint, and complained of feeling faint. I administered morphine hypodermically, and ordered ice to suck, pending removal to hospital. About half an hour later, in my presence, he again vomited a large quantity of blood (a pint to a pint and a half). Two hours after removal to hospital he vomited six ounces of blood. He was collapsed, the pulse 160, small and thready, the temperature 97° F., and the respiration sighing.

Rectal salines were administered every three hours, morphine hypodermically, and ice to suck. The patient revived a little, but was very restless. Next day he again vomited a small quantity of blood-streaked mucus. The systolic blood pressure was 100 mm. of mercury, and the diastolic 40 mm.; pulse pressure 60. Normal horse serum was injected, with morphine, and salines by the rectum every six hours. On the third day a radiograph was taken, but showed nothing abnormal.

Vomiting ceased after the second day, but the stools remained tarry for eight days after admission to hospital. The patient was given nutrient enemata as long as melaena persisted, and nothing by the mouth except ice to suck. After the eighth day milk combined with barley water and calcium lactate was given, and this was followed later by milk puddings and fish. He had no discomfort. A fractional test meal revealed no degree of hyperchlorhydria.

An uninterrupted recovery followed. The patient was discharged at the end of the third week. Before discharge another radiograph was taken, but nothing was observed apart from slight dilatation of the stomach.

Since discharge the patient has never felt better; he has regained a stone in weight, does not complain of any discomfort, the murmurs have become less marked, and the pulse slower, but still of Corrigan type, yet not so markedly water-hammer as before the haemorrhage occurred.

It may be worth while to mention that a claim was lodged by the patient under the Workmen's Compensation Act, but compensation was not granted.

Cwm, Monmouthshire.

F. O'SULLIVAN, M.B., B.Ch.

## British Medical Association.

### CLINICAL AND SCIENTIFIC PROCEEDINGS.

#### CAMBERWELL DIVISION.

At a meeting of the Camberwell Division of the British Medical Association, held at the St. Giles's Hospital, Camberwell, on April 24th, a discussion was opened by Dr. GUY BOUSFIELD on methods of combating diphtheria.

#### Diphtheria in Camberwell.

Dr. GRAHAM FORBES gave a survey, illustrated by charts, of the prevalence and incidence of diphtheria in Camberwell during the ten years 1918-27, dealing particularly with the

\* Dr. Graham Forbes last year gave a similar account of diphtheria in Hampstead, a summary of which was published on June 25th, 1927 (p. 1144).

incidence in the elementary schools. Diphtheria notifications in the borough, he stated, numbered 8,120 for all ages in this period, equal to an average attack rate of 3.03 per 1,000 (taking the 1921 census population), as compared with an average attack rate of 2.7 per 1,000 for all London. There were included in this total 2,632 cases under 5 years (attack rate 11.0 per 1,000) and 4,200 cases between 5 and 15 years (attack rate 8.0 per 1,000); for the combined age group under 15 years the Camberwell attack rate was 9 per 1,000, or slightly above the London attack rate for the decade of 8.7 per 1,000.

During the ten-year period the average annual death rate from diphtheria for all ages in the borough was 1.84 per 10,000, the rate for all London being 1.64 per 10,000. The average yearly death rate in the Camberwell age groups under 15 years was 6.2 per 10,000, against 6.0 per 10,000 for all London. In 1923, the year of heaviest diphtheria mortality in Camberwell, the case mortality was as high as 20.6 per cent. among children under 5, being 5.1 per cent. in the age group 5 to 15 years, and 8.2 per cent. for all ages. In 1927 the percentages had fallen to 4.2 in the age group under 5, 2.9 in the age group 5 to 15, and 3.16 for all ages. The year of the heaviest case mortality for all London was 1922, when it amounted to 7.4 per cent.

#### Incidence among School Children.

Comparing the attack rates in the school population, Dr. Graham Forbes showed that there had been a considerable divergence between the experience of Camberwell and that of London as a whole, but that as a rule the incidence had been higher in the borough. The average annual attack rate in Camberwell schools in the decade was 7.36 per 1,000, as compared with a mean rate of 6.8 per 1,000 for all London. The disease had fallen far more heavily upon children in the infant departments (between 4 or 5 and 6 or 7 years), with an average annual attack rate of 12.45 per 1,000; among children aged 7 to 13 years the average in 1918-27 was 4.69 per 1,000. Among older children the incidence of diphtheria in Camberwell had maintained a fairly constant level, but among infants the attack rate had fluctuated between 6.7 per 1,000 in 1919 and 18.9 per 1,000 in 1926. The steady rise in the school incidence from 1921 to 1926 had been almost confined to the infant departments, where in 1927, although there had been a considerable fall in the incidence for all ages, the attack rate was still at the high figure of 15.38 per 1,000.

#### Distribution of Diphtheria in Camberwell.

Study of the incidence in the four electoral areas into which the borough was divided, when viewed separately for the ten-year period, helped to focus local outbreaks peculiar to each of the four areas and their occurrence in the different years, as well as to show the extent to which prevalence had varied in each area, corresponding, it had been found, with the degree of population density. Those differences were displayed in the following table, arranged in order of highest school incidence and population density.

School Attack Rates per 1,000 School Population, 1918-27.

Area.	Camberwell North.	Peckham.	Camberwell North-West.	Dulwich.	Whole Boro.
Yearly average:					
Infants ... ..	13.4	13.2	12.5	9.4	12.45
Boys and girls ..	5.3	4.3	4.2	4.7	4.69
Combined ... ..	8.2	7.4	7.0	6.3	7.36
Population density*	177	125	120	60	105

\* Number of persons of all ages per residential acre.

Dr. Forbes said he need not dwell on the obvious significance of the heavy toll levied among children of the infant departments. The facts spoke for themselves, and pointed to the need for the fuller use of the means of protection at that susceptible period of life such as was being offered to parents at the infant welfare centre in Camberwell. He wished, in conclusion, to endorse the remarks of Dr. Bousfield with regard

to the value and importance of the Schick test and diphtheria immunization as the means of prevention, before which all other measures of controlling the spread of the disease hitherto available to the medical officer of health became insignificant and futile.

#### *Progress in Preventive Work.*

It was most encouraging to watch the progress of the new preventive work in London, and to note that, whereas eighteen months ago only two out of the twenty-nine metropolitan boroughs had introduced it in their infant welfare centres (Holborn and Westminster), there were now no fewer than twelve or thirteen boroughs which had begun or were shortly to begin the work. Others were recognizing its necessity as time went on. In Camberwell, as they were fully aware, Dr. H. W. Barnes, the medical officer of health, was successful in obtaining the sanction of his council to start preventive work in the welfare centre at 140, Camberwell Road in December, 1926, since when Dr. Bousfield had immunized some 1,200 children in the whole borough. That number represented only about one-twentieth of the most susceptible child population in Camberwell under the age of 5 years, and it would obviously be entirely premature to expect any influence on the general incidence and mortality of diphtheria from the immunization of so small a proportion of the unprotected children in the borough. In the protection against diphtheria, before any effect on the attack and death rates in a community could be claimed or expected, it was necessary to achieve the immunization of at least the majority of those susceptible, and to allow considerable time to elapse before conclusions could be drawn. Even in New York, where so much preventive work had been carried out and over 500,000 children had been inoculated in the past ten years, there remained over a million children non-immunized and mainly of pre-school age. Consequently it was not surprising that in the marked recrudescence and severity of the disease which 1927 had provided in the United States there should have occurred a rise in the diphtheria incidence and mortality above those of recent years, with so large a proportion of the child population in New York and other cities still unprotected. Immunization among the restricted populations in residential schools, institutions, and hospitals in Great Britain and other countries of the world had, however, afforded sufficiently sure results on which to rely when emphasizing its value and advocating its adoption and extension.

The employment in Great Britain for some years past of "toxoid-antitoxin," and now "toxoid," in which the toxin had, by exposure to the action of formalin, been rendered harmless but still potent to excite immunity response, had replaced the earlier use of toxin-antitoxin, and safely insured against such rare accidents as had occurred in the past in other countries where the latter was still being used. Notably was this the case with the recent disastrous events at Bundaberg in Queensland, the cause of which was still under investigation by the special commission.

## Reports of Societies.

### NARCOLEPSY.

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland on May 12th the President, Dr. G. E. NESBITT, showed a woman, aged 29, married, with three healthy children, who exhibited typical symptoms of the remarkable conditions known as narcolepsy.

Dr. Nesbitt said that he was indebted to Kinnier Wilson, whose graphic description of three cases he had heard last year, for ability to recognize this case. The patient presented herself at his out-patient department with a history of five or six years of attacks of "loss of power in herself," during which she became excited or laughed. These attacks were followed by an uncontrollable desire to sleep. She had had no illness of importance till she contracted influenza during the 1918-19 epidemic. Some time afterwards she struck the top of her head violently against the frame of a low door. This was followed by almost constant pain in the head, which she described as "terrible," and which was

said to have been relieved last year by a visit to a holy well. Soon after the injury the other attacks began, and had persisted since. Dr. Nesbitt added that the patient was a very intelligent woman; she gave a most picturesque and striking account of her curious affection, which she had previously despaired of making anyone understand, and she also quite appreciated its occasionally humorous aspect. A strong emotion, particularly laughter or mental absorption, but not fright, caused her to "flop" in a heap; her eyes shut and her head dropped. She lost all power in her limbs, and behaved "like an infant child when you stand it on the ground." Before she actually fell to the ground the attack passed off, but it recurred quickly, each time more severely. She finally had to sit down on the footpath or wherever she happened to be, and had the greatest difficulty in getting home. She felt exhausted and must get home to sleep, which she did for a variable period up to several hours. She had difficulty in rousing herself if she was disturbed during this sleep, but could do so by a strong effort. If awakened too soon there would be another attack. She sometimes suffered from attacks when she went to bed at night, but these were slightly different in character from the day attacks, probably due to the fact that she was already in bed. When the attacks occurred in the daytime she did not have them at night, and she was not able to bring one on voluntarily. No abnormal physical signs had been so far detected in the case, which appeared to be one of the so-called idiopathic narcolepsy. Some theories of the disease were then discussed by Dr. Nesbitt, including its relation to Parlor's theory of sleep. He added that an excellent summary was to be found in *Brain*, Part 3, vol. xlix (1926) by W. J. ADIE, who stated that the published cases numbered only about forty in all.

Dr. E. T. FREEMAN referred to a paper, by Sir James Purves-Stewart, in which it was suggested that the pituitary gland had some connexion with narcolepsy. Dr. BRIAN CRICHTON mentioned the case of a girl whose father had contracted encephalitis lethargica; about six months later she had developed curious symptoms. When amused she was unable to control the facial muscles, and she constantly dropped asleep while sitting in a chair. He raised the question of prognosis in these cases. Dr. C. MURPHY, referring to treatment, asked if Dr. Nesbitt thought that bromide and luminal, which were so efficacious in the treatment of cases of epilepsy, would be useful in cases of narcolepsy.

The PRESIDENT, replying, said that he thought Dr. Crichton's case was one of narcolepsy. The treatment was very unsatisfactory. Bromide, luminal, and all medications for epilepsy were unavailing, and treatment by suggestion also was useless. He had recently read of a case which had been treated by strychnine, opium, and caffeine, but without any effect.

### *Congenital Pyloric Stenosis.*

Dr. BRIAN CRICHTON read notes on a case of congenital pyloric stenosis, and showed x-ray photographs.

Mr. W. PRANSON, who had operated on the patient, said that there were two types of stenosis; in one the pylorus was very thick, pale, and vascular, and in the other there was no thickening of the pylorus and no enlargement, but the lumen was thick. In the present instance the pylorus had been situated right up in the liver, and lay very far back. Surgery in this condition had not, until recent years, been very satisfactory, and a great many different surgical procedures had been adopted from time to time. The most recent operation was that of Ramstedt, which was simple to perform. The patient had vomited for a few days after the operation, had then passed a mass of barium per rectum, and had not vomited again. He thought that it would have been wiser to have washed out the stomach before the operation, and got rid of the barium.

The PRESIDENT inquired about the operative mortality associated with this condition, as he thought that in a large proportion of cases the operation was not successful. Referring to the alternative treatment—Javage—he asked what action was to be expected from it except emptying the stomach.

Dr. C. M. SAUNDERS referred to a case with visible peristalsis and constipation which had been treated on medical lines. The patient had been given fluid by the rectum, and intraperitoneally with atropine and adrenalin; after about three months' treatment she recovered completely.

Dr. D. J. CANNON said that he had only operated on one case of congenital pyloric stenosis. In this case he had performed a gastro-enterostomy, and the child had died. He referred to a book by Dr. Barrington-Ward, in which there was a chapter on pyloric stenosis; it was stated that from 1907 to 1917 the medical mortality was 80 per cent., and that in 1925 the surgical mortality was 25 per cent., but in 1926 it had fallen to 4 per cent. It was also advised that patients should have gastric lavage and infusions of 5 per cent. glucose before operation, and that gas and oxygen should be used as the anaesthetic. He referred to the danger of intraperitoneal haemorrhage in these cases.

Dr. CHERTON, replying, said that the mortality in Scotland was 44 per cent. for both medical and surgical treatment. He thought that Dr. Still's figures were more favourable for medical treatment. If the child was seen in time, and was in a good condition, he thought that the chances of recovery by medical treatment were very favourable, but it must be realized that medical treatment including two washings out daily, and some children did not stand this well. It must also be remembered that with medical treatment some time was required to achieve a satisfactory result. The surgical mortality in these cases had fallen considerably in recent years.

Mr. PEARSON, replying, said that if a case was going downhill on medical treatment he thought it was a great mistake to wait till the patient was moribund before operating. Some of these cases had been operated on under spinal anaesthesia, but he thought that this method would be dangerous.

#### *Pituitary Infantilism.*

Dr. E. T. FREEMAN showed a case of pituitary infantilism of Lorain-Levi type.

Dr. Freeman said that this patient, who was a woman, aged 23, was 4 ft. 7 in. tall, with the general appearance and physical development of a child of 10 years old. She presented the following features: (1) Skeletal undergrowth—the body was of childish stature and ossification, but its parts were in due proportion, except the nose, which was remarkable for its size and aquilineity; (2) genital infantilism; (3) absence of adiposity; (4) normal or perhaps a slightly low sugar tolerance curve; (5) very small sella turcica; (6) normal basal metabolic rate; (7) normal renal efficiency (blood urea 28 mg. per cent., uric acid 3.3 mg. per cent.); (8) no persistence of the thymus; and (9) a very severe anaemia. Dr. Freeman remarked that the first three features were constant and characteristic findings in the condition. The fourth showed normal or perhaps slightly decreased action of the posterior lobe of the pituitary. The fifth was variable, as a large sella might be the site of a cyst which the gland had atrophied. The sixth was investigated to exclude a thyroid factor, the seventh to exclude the possibility of renal dwarfism, the eighth to exclude lymphatism, while the ninth was apparently a complication. When the patient was first seen pallor was the outstanding feature, and she had 3,300,000 red cells per c.mm. with 33 per cent. haemoglobin; on treatment with iron, arsenic, and liver the red cells improved to 4,650,000 and the haemoglobin to 45 per cent. The speaker added that it was an interesting speculation how far the anaemia might be responsible for the underdevelopment, but five months' treatment, while improving the anaemia, had not altered the height or weight in any degree. He thought that the anaemia was partly attributable to the fact that the patient scarcely ever left the house.

The PRESIDENT asked what was the expectation of life in these cases, and Dr. C. MURPHY asked if there had been any change in the patient's mental condition.

Dr. FREEMAN, in replying, said that these patients seldom lived very long. Some of them died within three to five years, but in such cases there was supposed to be some focal abnormality. The present patient's mentality was normal.

## STREPTOCOCCAL CELLULITIS.

At a clinical meeting of the Devon and Exeter Medical-Chirurgical Society on April 26th, with the president, Mr. A. L. CANDLER, in the chair, Mr. WAYLAND SMITH showed a case of streptococcal cellulitis occurring in a farmer aged 35.

Mr. Wayland Smith said that the patient had been admitted to hospital with a septic wound on the back of the left hand, cellulitis of the arm, and a temperature of 103° F. Localized abscesses formed subsequently in the arm and axilla, and cultures from the pus yielded a medium chained streptococcus; the blood culture was negative. One month later the man complained of sudden pain and swelling in the right ankle and wrist, and there had since been limitation of movements in the wrist and fingers. Mr. Wayland Smith remarked that the condition in this hand had not been unlike that met with in tenosynovitis of gonococcal origin, and there had been no sign of pus formation. A special feature of this case was the tendency to flare up after all the inflammatory symptoms had apparently subsided. The intense toxæmia, as evidenced by deep cyanosis and delirium, was also worthy of note. At the present time the wounded hand was actually in a better condition than the other. Mr. Wayland Smith emphasized the importance, from the point of view of prognosis, of identifying the type of streptococcus in these cases. He added that as regards treatment he was now relying on massage and radiant heat.

The PRESIDENT recalled Rosemayer's work on gall-bladder infections in connexion with the selective properties of the various streptococci. He quoted experiments in which organisms recovered from an inflamed gall-bladder, and also from a gastric ulcer, had produced similar lesions when injected into a dog. Mr. Candler commented also on the treatment of the present patient, and said he would be very unwilling to wrench the joints under an anaesthetic.

#### *Clinical Cases.*

Dr. JACKSON showed a case of tumour of the left cerebello-pontine area. Decompression had been performed by Mr. Worthington and the patient was now in fair health. Dr. W. GORRAN discussed tumours of the auditory nerve and the very low malignancy which was a characteristic feature. He commented on the wisdom of trephining on the left side as in the present case, so as to avoid disturbance of Broca's convolution. He also cited cases illustrating depression as a means of preservation of sight. Dr. FAYLE SEALE showed three cases of infantilism of Mongoloid type; Dr. EAGEN and Dr. GORRAN discussed the value of thyroid treatment in this condition in conjunction with the necessary institutional supervision. Dr. SEALE also showed a case of "hormonal imbalance" in a girl, aged 14, who had enlarged glands in the neck and premature sexual development, menstruation having commenced at the age of 10. Other diagnoses suggested were Hodgkin's disease and tuberculosis of the suprarenals. Mr. B. DYBALL showed a case of hydronephrosis in a man aged 28. A radiogram revealed the right renal pelvis as being twice the normal size. At the operation it was found that the pelvis of the kidney was covered with a leath of varicose vessels. Mr. Dyball also showed a doubtful case of abdominal tumour in which the diagnosis lay between aneurysm of the abdominal aorta, or of the coeliac axis, pancreatic cyst, and bone tumour. Dr. GORRAN suggested sarcoma was more probable, since the tumour had decreased in size and was not tender; there was no modification in the pulses, the murmur which was heard over the tumour was slight, and he could not detect definite expansile pulsation. Dr. F. A. RORER showed a case of marked cyanosis in a man, aged 45, which continued for some twenty years. The heart was much enlarged transversely and the liver was increased in size. Mr. NORMAN LOCK showed a case of mastitis in a youth aged 20. Mr. DYBALL read notes on a case of retroperitoneal fibroma in a woman aged 37, and on a case of sarcoma of the ileum which had caused intestinal obstruction. Dr. RORER reported a case of pyelophlebitis, in which the cause was found, on necropsy, to be a gangrenous appendix associated with multiple abscesses of the liver and general peritonitis.

## Rebelsus.

### MEDICAL HISTORY.

IN his *Short History of Medicine, introducing Medical Principles to Students and Non-Medical Readers*,<sup>1</sup> Dr. CHARLES SINGER, who is so widely recognized as a writer on this subject and on the evolution of scientific thought, follows his previously expressed ideal in treating medical history from the point of view of ideas and not biographically; and accordingly this work tells the story of the scientific elements in medicine, other aspects being passed over in a silence which (as he points out in an eloquent preface) must not be interpreted as the silence of contempt. Among the graceful acknowledgements there is a rather retiring dedication of the work to Dr. E. T. Withington. Dr. Singer is a vitalist, and this, as he admits, may modify his treatment of the subject matter, but others may feel that this is rather a refreshing attraction.

The history is very suitably considered in six periods: Ancient Greece; the heirs of Greece, from 300 B.C. to about A.D. 200, including the Alexandrian School, of course, and Galen; the Middle Ages; the rebirth of science, extending from 1500 to about 1700; then the period of consolidation up to about a hundred years ago; and lastly, occupying more than half the volume, the period of scientific subdivision. In an attractive account of ancient Greek medicine, which grew out of the obscure Minoan civilization, Dr. Singer recalls that the duration of progressive and scientific medicine lasted for eight hundred years, whereas our own system has been developing for little more than four and a half centuries. The wisdom of Hippocrates is illustrated by selections from the *Aphorisms*, and his honest accuracy of clinical description by cases now recognizable as diphtheria and as showing Cheyne-Stokes respiration. The influence of Aristotle on biological conceptions and his vitalistic view of the activity of the soul—which he termed "entelechy," and is here translated as the "indwelling perfectibility" or "purposiveness"—are well brought out, and Harvey's views on fertilization are shown to be practically identical with those of Aristotle two thousand years before. Passing on to the rebirth of science and the renaissance of medicine, which is of special interest in this year of the tercentenary of Harvey's *De Motu Cordis*, the revival of anatomy under the independent mind of Leonardo da Vinci is described, Harvey's work is well summarized, and the subsequent influence of the microscope clearly shown. The period of consolidation was marked by the rise of clinical teaching and of morbid anatomy under the influence of J. B. Morgagni, who is rightly described as introducing the "anatomical concept" into medicine, but it also saw the early study of vital statistics and Jenner's vaccination. The difficulty of naming and dividing the several periods has been very happily solved, and perhaps more especially the last period, extending up to the present time. Dr. Singer's admirable survey embraces recent developments; for example, such varied subjects as preventive medicine, cellular pathology, anaesthesia, bacteriology, the advance of surgery, the new psychology, endocrinology, and vitamins are passed in review.

This well-written and beautifully illustrated work closes with an epilogue, in which the present-day tendencies, needs, and risks are considered in a philosophical tone, and a warning is thrown out against the adoption of too optimistic an outlook. Although data accumulate apace, their correlation, which is the crying need, lags; many, the author says, consider that the general level of medical research has fallen of late years, and there are, as everyone must admit, lamentable gaps in our knowledge. That this book deserves a popular success there can be no doubt, and it is published at a most reasonable price.

<sup>1</sup> *A Short History of Medicine, introducing Medical Principles to Students and Non-Medical Readers*. By Charles Singer, M.D., D.Litt.Oxon., F.R.C.P. Oxford: The Clarendon Press, 1928. (Demy 8vo, pp. xxiv + 348; 143 figures. 7s. 6d. net.)

### FOODS AND FOOD ANALYSIS.

THE late Dr. A. WYNTER BLYTH and Mr. M. WYNTER BLYTH's textbook *Foods; their Composition and Analysis*,<sup>2</sup> passed through six editions, the last of which appeared in 1909, and now it has been revised and partly rewritten by Mr. H. E. COX, public analyst for Hampstead. The work is primarily intended as a manual for the use of analytical chemists, and the greater portion comprises detailed descriptions of methods of analysis of foodstuffs and of the procedures for detecting adulteration. The first part of the book has a more general interest, for it contains a very interesting history of the adulteration of human food. The history of this sordid aspect of commerce dates back to classical times, but apparently adulteration of bread was a fairly chronic social problem throughout the whole of European history. This section concludes with a summary of the present law regarding adulteration, and in particular the regulations regarding the use of preservatives (1924) are given *in extenso*. The Acts regulating the sale of food and drugs are given in appendices at the end of the volume. The value of a work of this kind, which is a reference manual of practical technique, can only be determined by experience of it in practical use, but the book appears to give a full detailed account of all the important methods of analysis, and recent practices, such as the electrolytic estimation of arsenic, have also been included. Certain sections would, however, have been benefited by a more drastic revision. For example, 100 pages are devoted to milk, cream, and butter. In this section a most interesting history is given of the humoral theories of milk secretion, and of such out-of-the-way subjects as witches' milk. There are, however, scarcely half a dozen references to work done subsequent to 1904. Moreover, Koch's views on bovine tuberculosis are quoted *in extenso*, in particular the view that the infection of human beings by bovine tuberculosis is a very rare occurrence. The book states that this view is contested by other pathologists, but it would have been better either to give a proper presentation of the modern views on this important subject, or else to have omitted it altogether.

*Oils, Fats and Fatty Foods*,<sup>3</sup> by E. R. BOLTON, with a chapter on vitamins by Professor J. C. DRUMMOND, is a second edition of *Fatty Foods*, by Bolton and Revis, which appeared in 1914. The author explains in the preface that the intensive study of fatty foods necessitated by the fat shortage in the war resulted in great progress in knowledge, and particularly in a marked increase in the standard required for refined fats and oils intended for human consumption. This advance has resulted in a considerable expansion of the book, but the author points out that comparatively few new analytical methods have been devised; the advance having consisted chiefly in the improvement of existing methods. The book gives a full account of all the chief methods, both physical and chemical, employed in the testing of oils and fats. One curious fact that is brought out is the enormous variety of fats that are used in the production of margarine. It is somewhat disquieting to learn in regard to this (p. 110) that "there is in a large number of cases absolutely no method of arriving at proof that the constitution of any sample of butter fat is due to sophistication and not to natural causes." The whole book bears evidence of careful selection, for full details are given of the best methods of analysis, and no space is wasted on methods that are solely of historical interest. Professor J. C. Drummond contributes an interesting chapter on fat-soluble vitamins—namely, vitamins A, D, and E—and gives a short account of the chief facts that have been established regarding these substances. This chapter can be recommended to any who want to find a short, clear, and accurate summary of our present knowledge of this subject.

<sup>2</sup> *Foods; their Composition and Analysis*. By the late Alexander Wynter Blyth, M.R.C.S., F.I.C., and Meredith Wynter Blyth, B.A., B.Sc., F.I.C. Seventh edition; revised and partly rewritten by Henry Edward Cox, M.Sc., Ph.D.Lond., F.I.C. London: C. Griffin and Co., Ltd. 1927. (Med. 8vo, pp. xxv + 619; 90 figures. 30s. net.)

<sup>3</sup> *Oils, Fats and Fatty Foods*. By E. Richards Bolton, F.I.C., F.C.S. With a chapter on vitamins by J. C. Drummond, D.Sc., F.I.C. Being a second edition of *Fatty Foods*. By E. Richards Bolton and Cecil Revis. London: J. and A. Churchill, 1928. (Roy. 8vo, pp. xvi + 416; 34 figures, 12 plates. 30s. net.)

## DERMATOLOGY.

WE have received the fourth edition of Dr. DARIER's well-known *Précis de Dermatologie*,<sup>4</sup> undoubtedly one of the best textbooks on the subject in any language. It has now been before the medical public for just on twenty years, and although grown in size maintains its characteristics. We may remind our readers that it consists of two distinct portions, approximately equal in size, the first devoted to a description of the morphology of the lesions which are the fruit of pathological changes in the skin; and the second (nosology) an account of the cutaneous diseases of which the etiology is at all events in some measure understood. This arrangement involves a certain amount of repetition, but not so much as might be supposed; because those numerous conditions of whose etiology we are entirely ignorant (psoriasis is the best example) are described only in the first part. Like Brocq, with whom, no doubt, he must often have discussed these matters, Darier refuses to dignify such things as eczema, psoriasis, and urticaria with the title of diseases; he regards them as mere clinical syndromes of doubtful, obscure, or complicated origin. Those pathological conditions alone are considered diseases, and worthy of a place in nosology, which have a definite etiology; whether microbic, physical, or chemical. This arrangement at least avoids the difficulties of classification—always a bugbear to dermatologists—and has permitted the author to write a lucid and instructive manual of his subject.

Dr. Darier describes his book as a "précis" of dermatology, of which the nearest English equivalent is "summary," and states that he wishes it to serve as an introduction to the authoritative treatises (les traités magistraux) on the subject. This "summary" consists of over eleven hundred closely printed pages; how long, then, should a treatise be? As a matter of fact, except for the omission of references to original papers, this is a treatise, and a very good one. The only criticism we have to make is that the new edition is somewhat awkward to handle, because the thickness of the volume is excessive in proportion to the size of the page, which is the same as in the first edition, though that had less than half the present bulk. The illustrations, over two hundred in number, are clear, though rather small.

## TRAUMA AND COMPENSATION IN OBSTETRIC AND GYNAECOLOGICAL CASES.

THERE are many excellent works dealing with obstetrics and gynaecology; Dr. LINDSAY, in his book on *Trauma and Compensation in Obstetric and Gynaecological Cases*,<sup>5</sup> has, however, provided information and guidance not to be found in these works. It must be almost unique for an obstetrician and gynaecologist to have had the advantage of a medico-legal training such as Dr. Lindsay acquired as assistant to the professor of forensic medicine in Glasgow University, and his cases bear out the thoroughness of this training. His book fills a gap in medico-legal literature. Starting with a description of the type of medical report required, he deals, among other points, with pregnancy and the ability to work, trauma in relation to abortion and premature birth, information obtained from the examination of the newly born child, and trauma in relation to various gynaecological conditions. The book is full of practical points and well illustrated with cases. We strongly recommend it to anyone dealing with compensation work.

## ACUTE APLASTIC ANAEMIA.

IN a monograph on *Acute Aplastic Anaemia*<sup>6</sup> Dr. HAYES SMITH describes in full detail his daily notes and impressions on a case in a child of 2 years. His thesis is that the activity of the bone marrow as a haemopoietic organ is controlled by a liver hormone, and that the primary fault in acute aplastic anaemia is a toxin acting on the liver and inhibiting this hormone action. In this

case the deficient hormone was replaced by injections of liver substance which were followed by an immediate bone-marrow response and a quick return to a normal blood picture. Clearly all depends on the correctness of the diagnosis, and a pleasing feature of the paper is the full and careful way in which the blood examinations by Dr. C. J. Young are recorded; but not everyone will be ready to accept a diagnosis of aplastic anaemia on the absence on two occasions of platelets and polymorphonuclear leucocytes, when the haemoglobin value was only once as low as 58 per cent. and the patient was not sufficiently incommoded to be kept in bed. The author realizes the danger of drawing conclusions from one case, but he points out that observations on a single rare case have left their impress on medicine. A short glossary is given at the end, but no one who needs to be told that haemopoiesis means blood formation and that thrombocyte is a synonym for blood platelet can possibly read Dr. Hayes Smith's views with any profit. In any future edition we hope that the author will correct the slip that makes "noxus" the singular of "noxa."

## ELECTRICAL DANGERS.

THE small book on the accidents and dangers of electricity,<sup>7</sup> by Dr. PAUL DUHEM (électro-radiologiste des Hôpitaux de Paris), gives a very practical and concise account of the subject. The author was inspired to take up this work by the accident to Dr. Jangeas, who was killed instantaneously whilst conducting the screen examination of a patient. The accident was caused by the formation of a short circuit owing to the non-insulation of certain wires. The author starts by discussing the physiological action of electric currents, and particularly the cause of death in electrocution. The text is illustrated throughout by the citation of accidents which have frequently occurred from strange and sometimes mysterious causes. Other chapters deal with the etiology, the symptomatology, and the results and complications which may follow from a shock which does not kill. The two concluding chapters are on treatment and on preventive measures. As regards the latter, it is clearly shown that ignorance and carelessness play an important part in many accidents, but that defective wiring and apparatus have frequently much to answer for.

Radiologists and electrologists will find a good deal of useful and practical material in this book, but it is by no means written for them and doctors alone; it should be useful, in these days of electricity, to practically everyone.

## HARVEY'S WORKS IN ENGLISH.

IN reviewing last week Mr. GROFFREY KEYNES's admirable bibliography of the writings of William Harvey we mentioned that he had edited also, with a view to the tercentenary celebrations, the first English text of Harvey's anatomical exercises. This charming volume has been printed and made in Holland with the types of Joan Michael Fleischman and of Christopher van Dijk, and is published by the Nonesuch Press.<sup>8</sup> It contains the English translation of the *De Motu Cordis* and the *De Circulatione Sanguinis*, of which the first edition was published by Richard Lowndes at the White Lion in Duck Lane, London, in 1653, and the second in 1673. In preparing the present text Mr. Keynes has collated these two editions, and has done such polishing as seemed necessary. The two plates illustrating the function of the valves in veins which accompanied the original Latin edition of 1628 were omitted from the first two English editions, although the references to them remained in the text; to remedy this defect an excellent drawing has been made from the life by Stephen Gooden for the present edition, and engraved on copper by C. Sigrist. These and other matters are explained in the editor's postscript and textual

<sup>4</sup> *Précis de Dermatologie*. Par J. Darier. Quatrième édition, revue et augmentée. Paris: Masson et Cie. 1928. (Gr. 8vo, pp. xviii + 1102; 223 figures. Paper cover, 85 fr.; bound, 100 fr.)

<sup>5</sup> *Trauma and Compensation in Obstetric and Gynaecological Cases*. By Douglas Marshall Lindsay, M.D., F.R.F.P., and S. Glas. Edinburgh and London: W. B. Jones and Co., Ltd. 1928. (Demy 8vo, pp. 172. 7s. 6d. net.)

<sup>6</sup> *Acute Aplastic Anaemia*. By A. Hayes Smith. London: H. K. Lewis and Co., Ltd. 1928. (6 x 9), pp. viii + 80; 3 charts. 6s. net.)

<sup>7</sup> *Accidents et Dangers de l'Électricité*. By Dr. Paul Duham. Paris: Gauthier-Villars et Cie. 1928. (5½ x 8 in., 2 + 74; 7 figures. 10 fr.)

<sup>8</sup> *The Anatomical Exercises of Dr. William Harvey: De Motu Cordis, 1628; De Circulatione Sanguinis, 1628*. First English text of 1653 now newly edited by tercentenary celebrator Groffrey Keynes. On the occasion of the 300th anniversary of the text of *De Motu Cordis* by the Nonesuch Press. (5 x 8½), pp. xvi + 202. 25s.)

notes. The volume is one which everyone who possesses it will value, both for what it contains and for the pains lavished upon its production by editor and printer alike. For eighty years Robert Willis's English rendering of Harvey's anatomical exercises has held the field; now, thanks to Mr. Geoffrey Keynes's scholarship and industry, we have the text of Harvey's own time, printed on good paper and beautifully bound.

### NOTES ON BOOKS.

THE 1927 issue of the *Handbook to British Malaya*,<sup>9</sup> edited by Mr. R. L. GERMAN of the Malayan Civil Service, is an unusually attractive guide, and supplies, especially in the section on life in Malaya, answers to many questions of real practical importance to aspirants for employment there which are too often overlooked in similar publications. The chapter on hygiene and sanitation shows the unusually high proportion of specialist appointments available on the European establishment of the various medical departments. Apart from the staff of the King Edward VII College of Medicine, Singapore, which numbers 11, the total medical establishment of 42 in the Straits Settlements includes 9 specialist posts, and the establishment of 91 in the Federated Malay States, 22. Entry to the College of Medicine, which gives a full six years' course and confers a diploma registrable in the United Kingdom, is restricted to candidates born or educated in Malaya; the number of students in 1926 was 113. Registration of births and deaths is compulsory throughout British Malaya, and is in course of adoption by the native States. Vaccination is compulsory before the age of 7 years, and the effective operation of the Quarantine and Prevention of Diseases Acts is evidenced by the relatively low incidence of zymotic diseases. Maternity and infant welfare work is now firmly established, both in Singapore and the Federated States. Progress is being made with the prevention of malaria under the direction of the Federated Malay States Malaria Advisory Board, and there is a Public Health Education Committee for the spread of information of general health interest. The main causes of death are malaria—characterized as "preventable, but at a cost"—venereal diseases, dysentery, and diarrhoea. Ankylostomiasis, almost universal among the Asiatic population, gives rise to symptoms in a relatively small number of cases, and has the low death rate of 0.5 per 1,000. The general health of the European population is said to be good, though cases of neurasthenia have recently increased "here as elsewhere." The book is lavishly illustrated with photographs of real beauty, and there is an adequate map.

Alive to the importance of establishing definite knowledge on the distribution of those mosquitos which are vectors of human and animal disease, about which accumulated facts up to the present time are very meagre, the South African Institute for Medical Research has had under consideration for some time a scheme for a mosquito survey of South Africa. A beginning has been made, and the booklet now published by the Institute entitled *A Mosquito Survey of Certain Parts of South Africa*,<sup>10</sup> by INGRAM and DE MEILLON, deals with the results of investigations made in portions of the Northern Transvaal and in the coastal belt of Zululand. The text is written very much in the form of a diary, and its value lies strictly in its local application. At the end descriptions are given of new mosquitos collected in Zululand, and of the larvae and pupae, not hitherto described, of certain other mosquitos.

The Department of Health of Canada has published a diamond jubilee edition of *The Canadian Mother's Book*,<sup>11</sup> (first edition 1923) by Dr. HELEN MACMURCHY, chief of the Dominion Division of Child Welfare. The book is printed in clear type with wide margins, and is illustrated by photographs of delightful-looking babies which are certain to catch the mother's eye and to hold her attention. Simply and appealingly written, it contains all information needed by an expectant mother. The right method of treating the baby when it arrives are next dealt with. Plain medical directions based on scientific knowledge are apt to be "dry as dust" when put into simple language, but Dr. Macmurehy has succeeded in infusing a note of happy joy into her little book. It is certain to arouse interest and enthusiasm in all who have the maternal instinct.

<sup>9</sup> *Handbook to British Malaya, 1927*. Published by authority and compiled by R. L. German. London: The Malay States Information Agency, 1928. (6s. x 8½, pp. 191; illustrated. 2s. 6d. net; post free, 3s.)

<sup>10</sup> *A Mosquito Survey of Certain Parts of South Africa* (Part I). By Alexander Ingram, M.D., and Botha De Meillon, B.Sc. (Honours). Institute for Medical Research, No. 1 in Institute for Medical Research.

By Helen Macmurehy, M.D. Tor. Blue Books, Mother's Series, No. 1. Canada. Ottawa: F. A. Acland.

The *Handbook of Photomicrography*,<sup>12</sup> by H. LLOYD HIND and W. BROUGH RANGLES, which was first published in 1913, has been revised, many sections having been rewritten in order to bring the information up to date. In giving an account of modern methods the practical requirements of students and medical practitioners have been carefully kept in mind. Such subjects as stereoscopic photomicrography, cinematomicrography, and colour photomicrography have been treated simply but effectively. The wealth of illustrations indicates the widespread application of photomicrography to various sciences and industries, and it is pleasing to note that British instruments figure very largely. The book can be recommended to those who are concerned with a subject of increasing importance and interest.

Dr. MUNN CRAWFORD has written a useful little *Materia Medica for Nurses*.<sup>13</sup> Only drugs in common daily use are dealt with, and in addition to the important preparations, doses, action, and uses of each drug, a note is appended of the symptoms of and treatment for an overdose of some of the more poisonous. The book is clearly written, the descriptions of the actions of the drugs are made as interesting as the subject allows, and the author's aim of producing a handbook useful both for examination purposes and for reference has, we think, been achieved.

*Getting Well and Staying Well*,<sup>14</sup> by Dr. JOHN POTTS of Fort Worth, Texas, is one more example of a type of book that has of late years been growing very common in America—a book written for both doctor and patient. It deals, of course, with pulmonary tuberculosis. The great objection to this class of book is that it is too elementary for the doctor and too advanced for the patient. On the whole, the present volume is better than most we have read; but we find it difficult to imagine that any doctor in this country would put it into the hands of a lay person.

Dr. ESDAILE's book *Economic Biology*<sup>15</sup> was written for students of social science who study applied biology. It is really a kind of "materia domestica"—a collection of facts concerning animals and plants which are, or may be, closely associated with man and his household. It is not, however, merely a dictionary in which the angry householder may look up a method of exterminating furniture beetles, but an orderly guide for systematic biological studies, the types chosen for special investigation being creatures familiar to us in our homes.

Major HASSAN SUHRAWARDY's *Manual of First Aid for India*,<sup>16</sup> first published in 1925, has reached a second edition, and therefore seems to have met a public want. As its name implies, it is specially adapted for use in India. It fulfils its purpose, and should be of service to the class of workers for whom it is intended, though there is perhaps somewhat more anatomy and physiology than necessary. Fracture of the lower jaw is, no doubt, usually compound, but it is hardly correct to say (p. 74) that it is always so. The general get-up—plates, paper, and type—is good. No publisher's name appears on the title-page; presumably the book may be obtained through the author at the office of the Chief Medical Officer, East Indian Railway, Calcutta.

<sup>12</sup> *Handbook of Photomicrography*. By H. Lloyd Hind, B.Sc., F.I.C., and W. Brough Rangles, B.Sc. Second edition, revised. London: G. Routledge and Sons, Ltd.; New York: E. P. Dutton and Co. 1927. (Demy 8vo, pp. xii + 295; 76 figures, 44 plates. 16s. net.)

<sup>13</sup> *Materia Medica for Nurses*. By A. Munn Crawford, M.D., F.R.F.P.S.G. London: H. K. Lewis and Co., Ltd. 1927. (Cr. 8vo, pp. viii + 85. 3s. 6d. net.)

<sup>14</sup> *Getting Well and Staying Well*. A Book for Tuberculous Patients, Public Health Nurses, and Doctors. By John Potts, M.D. Introduction by J. B. McKnight, M.D. London: H. Kimpton. 1927. (Post 8vo, pp. 223. 8s. 6d. net.)

<sup>15</sup> *Economic Biology, for Students of Social Science*. By Philippa C. Esdaile, D.Sc. Part I, Harmful and Useful Animals. London: University of London Press, Ltd. 1927. (Demy 8vo, pp. xv + 175; 150 figures. 7s. 6d. net.)

<sup>16</sup> *A Manual of First Aid for India*. By Major Hassan Suhrawardy, M.D., F.R.C.S., D.P.H. Second edition, revised and enlarged. (Price R.1.)

### PREPARATIONS AND APPLIANCES.

#### THEOSOL AND CITOBARYUM.

We have received samples of the following drugs, which are sold in this country by Messrs. H. R. Napp, Ltd.

"Theosol" is theobromine calcium salicylate (manufactured by Messrs. Knoll). The chief advantage claimed for this compound over the Pharmacopoeial compound theobromine and sodium salicylate is that the former is less soluble, and hence passes through the stomach to be dissolved in the intestines. This obviates gastric irritation.

"Citobaryum" is a preparation of barium sulphate prepared by Messrs. E. Merck, Darmstadt. The special advantage claimed for the preparation is that it is in a very finely divided state. Hence it forms a creamy fluid, which is free from objectionable grittiness and sediments slowly.

# British Medical Journal.

SATURDAY, JUNE 2ND, 1928.

## THE FUNDAMENTALS OF A MEDICAL SERVICE.

WHETHER the medical services of the British Isles should rest on a public or a private footing is from time to time a topic of debate in both the lay and the medical press, and, whatever plan may be put forward as likely to keep the balance adjusted, it is usually urged that the one thing needful to bring the facilities of modern medicine within reach is organization, co-ordination, or team work, as it is variously called. It is rather remarkable that organization, which is, after all, merely an administrative process, should occupy such a prominent place in these discussions, and many who lay great stress upon it might perhaps be at a loss to explain why they concentrate so much upon the form and pass the substance by. Their reason, however, is not far to seek. They take the fundamentals for granted, and are justified in so doing, for these fundamentals are an educated medical profession and an enlightened public, both of which this country possesses, the former guaranteed under statute, the latter rapidly increasing in number as information spreads.

Under the Medical Acts the General Medical Council, which keeps the register of duly qualified medical practitioners, has also a duty as regards their education. The medical curriculum, which the Council supervises, affords not only a scientific training, but also, by including special medical subjects and providing a final clinical training in medicine, surgery, midwifery, and children's diseases, turns out the young graduate reasonably well equipped to begin the practice of medicine. Many, in addition, take a hospital post in order to extend their experience. The general practitioner, too, has become increasingly conscious of the need to keep himself abreast of the medical thought and progress of the day. This is so well known to the general public that unqualified practice, although not illegal, is at a disadvantage, which is further accentuated by the exclusion of the unqualified from the insurance service of the nation. The brass plate on the qualified doctor's door conveys to all comers the information that the name it bears is that of a person who has received a recognized training in the art which he claims to practise.

As regards the public its medical enlightenment is now quite appreciable. New forms of treatment and reports by scientific medical workers on research and kindred subjects figure prominently in the lay press in news items or leading articles, and the health propaganda movement—as a rule discreet and well informed, and more so in the past year or two—does much to acquaint people with the applications of medical knowledge to everyday life, and with the facilities offered by local authorities for treatment in

special cases. We are far from asserting that the doctor in this country has reached his zenith, or that the British public is beyond the need of further health instruction, but as regards the position at the present time, it is not too much to say that the fundamentals of an efficient medical service are with us, and that organization is the principal pre-requisite for bringing them into effective working.

In the United States, with fewer traditions and a new population of mingled breed that has yet to learn good American ways, the arrangement and control of the medical service present other difficulties. There is much to be done on the fundamental relations, for all is not well, as it would appear, between the American profession and the public. In a recent work Mr. H. H. Moore<sup>1</sup> remarks that the populace of the United States owns a divided allegiance on the one hand to legitimate medicine, and on the other to false cures. A doctor in Philadelphia found that 34 per cent. of his patients had been attended by some unqualified practitioner within three months of his own attendance upon them. A former Health Commissioner of New York City compiled a list of fifty-seven pseudo-medical cults, including such portents as Biodynamic-chromatic-therapy, Naturology, and Zodiac-therapy. The more reputable departures from the normal, such as Osteopathy, Chiropractic, New Thought, Applied Psychology, and Christian Science, number more adherents than the regular profession. The irregular practitioner would also seem to be making his way into official life: in 1923 three medical officers of health in Minnesota were osteopaths.

Under such conditions it is easy to understand that the public may require enlightenment in order to discriminate between the right and the wrong type of doctor. The *Chicago News*, giving guidance on the point, proposed two useful tests. The first was that the name of the good doctor was rarely seen in print, and the second that in making examinations he required the patient to remove clothing which might interfere with the detection of signs and symptoms. The New York State Department of Health, again, advised patients by wireless that they should not be unduly impressed by an elaborate consulting room. That advice of this kind should be necessary is an interesting commentary on the standing of the doctor in the estimation of the unenlightened sections of the American public. An adjustment of these fundamentals is a pre-requisite before organization can be effective.

Thanks largely to the continued efforts of the American Medical Association and the Association of American Medical Colleges, much has already been done in the United States to raise the general status of the medical profession. As we noted twelve months ago, in an article on medical education and practice in America,<sup>2</sup> the 400 medical schools, many of which were illusory, have now been reduced to 79, and the efficiency of those that have survived is secured under regulations. This is a noteworthy step

<sup>1</sup> *American Medicine and the People's Health*. By Harry H. Moore, Public Health Economist, United States Public Health Service. New York and London: D. Appleton and Co. (5½ x 8½, pp. xxii + 647) 16 plates. 21s. net.)

<sup>2</sup> *British Medical Journal*, May 28th, 1927, p. 979.

forward, but, medical licensing has, regrettably, failed to move in concert. In most States the irregular healer is licensed on the same footing as the well-trained graduate, and the law may regard with equal favour the Zodiac-therapist and the finished product of a high-grade medical school. It is little wonder if the citizen is in doubt as to what the brass plate—or its American equivalent—stands for, and needs the guidance of the daily press and wireless when he is choosing his medical attendant. More than organization would appear to be required to produce an efficient medical service in America. The question of licensing is fundamental, and should be adjusted first. There should be no place for Zodiac-therapy or other forms of remedial magic in a country possessing the genuine medical resources of the United States.

#### THE LISTER INSTITUTE.

THE annual general meeting of the Lister Institute of Preventive Medicine was held on May 23rd, when the governing body presented its thirty-fourth annual report to the members. In recording the death of Lord Iveagh last October it is recalled that the endowment of the Lister Institute in 1898 was the largest of his benefactions for the advancement of medicine by research, and enabled the objects for which the Institute was founded to be pursued on a scale that had previously been impossible. Reference is made also to the death of Sir Dawson Williams, whose place as representative of the British Medical Association on the council has been filled by the appointment of Professor W. E. Dixon. The various sections of the report give evidence of continued activity in all the many branches of research undertaken in the departments of the Institute. Acknowledgement is made of the financial support given by the Medical Research Council, the Department for Scientific and Industrial Research, and the British Empire Cancer Campaign to skilled investigators working at the Institute. The Medical Research Council provides salaries for the staff of the National Collection of Type Cultures, and for three workers in the Department of Experimental Pathology, and it has entrusted the Department of Biochemistry with a lengthy inquiry into the vitamin content of Empire products and the effect of preservation and storage thereon, the cost being defrayed by a grant from the Empire Marketing Board. In the Department of Bacteriology Professor Ledingham has extended his studies on vaccinia and variola, Dr. Eagles completed an investigation of rough and smooth forms of streptococci from scarlet fever sources, with special reference to variations and virulence, and Dr. Arkwright's work on bacterial variation and the antigenic structure of bacteria has been continued. Dr. Koronchevsky and his fellow workers have investigated testicular and prostatic hormones and the effects of lipid ovarian extract and parathyroid extract on nitrogen metabolism. Further researches have been made by Dr. Harriette Chick and Miss Roscoe into the two active constituents of water-soluble vitamin B, provisionally called B<sub>1</sub> (the antineuritic) and B<sub>2</sub> (the so-called "antipellagra" vitamin). Their experiments on nutrition indicate that conclusions regarding the biological value of casein and other proteins now stand in need of revision. Both vitamin B<sub>1</sub> and B<sub>2</sub> are present in yeast, and information is accumulating regarding the distribution of vitamin B<sub>2</sub> in different whole cereals and their constituent parts. Other vitamins and their sources have also been studied during the year, and in this connexion the biological action of light has received close attention. In their work on cancer

Drs. Lumsden and Stephens have found that, by combining the use of antiserum with adrenaline, about 50 per cent. of rat sarcomata could be made to disappear, and that the rats so cured were immune to subsequent implantation of sarcoma and also of rat cancer. It appears that antibodies specifically lethal to malignant tumour cells can be produced, and that local treatment by an implanted tumour growing in a rat will yield a vaccine which causes active tumour immunity in the animal treated. Investigations of foot-and-mouth disease have been continued throughout the year in a laboratory and animal house set apart for the purpose. Lastly, we may recall that (as noted in our issue of May 5th) the Institute has accepted an invitation from the International Committee for the Study of Infantile Paralysis to take part, with five other scientific bodies in America and Europe, in a joint attack upon the problem of poliomyelitis.

#### PROFESSIONAL ORGANIZATION.

It is highly desirable that members of the medical profession should not overlook the important and very interesting Herbert Spencer Lecture, delivered at Oxford on May 18th by Professor A. M. Carr-Saunders, on *Professions: their Organization and Place in Society*.<sup>1</sup> It has been published by the Clarendon Press as a booklet containing only some thirty pages of reading matter, but these pages are full of wisdom and contain much food for thought. The theme of the lecture and the general nature of its argument may be indicated by a short, but necessarily inadequate, summary. A profession is defined as "an occupation based upon specialized intellectual study and training the purpose of which is to supply skilled service or advice to others for a definite fee or salary." Further, a profound distinction between manufacturers and dealers on the one hand, and professional men on the other, is that the latter "do not buy and sell material goods as an essential feature in the performance of their functions." It is useful to bear this in mind when claims are made, as is sometimes the case, that opticians, druggists, and pharmacists are members of "professions." Even chiropodists would seem to have a better claim unless any of them are vendors of boots also. As soon as a profession emerges, its members, moved by common interests, form a professional association. Moreover, the tendency is towards the dominance of a single association in each profession. Minor rival associations always tend to die out. This is apart from those associations which deal solely with the science or subject-matter of their profession; these may be numerous. Two of the chief objects of a professional association as here understood are "to bring up the qualifications of all who hold themselves out as practising the craft to a certain minimum standard, and to enforce the rules of honourable conduct." Some features of such codes of ethics are common to all professions; for example, (1) the rule against advertising; (2) "making the fee or salary paid for service rendered the sole remuneration or advantage which a practitioner receives"; (3) prohibition of the abrogation of one's position as responsible adviser in order to facilitate and cover the actual delegation of responsibility to an unqualified person. When examined, such codes or rules are found to be entirely in the public interest. Some criticisms may be made, "but they are small evils from the point of view of the public compared with the state of things which obtains when the competent and responsible members of a profession fail to achieve these objects." A third object of a professional association is to raise the status of the profession, and "it is impossible to ignore the fact that the status of the professional

<sup>1</sup> *Professions: their Organization and Place in Society*. By A. M. Carr-Saunders, M.A., Professor of Social Science in the University of Liverpool. Oxford: The Clarendon Press; London: H. Milford, Oxford University Press. 1928. (Med. 8vo, pp. 31. 2s. net.)

man must be dependent on the salary or fees which he receives." It is easy to suggest that selfish motives are predominant in this connexion; but "if a just conclusion is to be reached it must be remembered that the activities of the associations are restricted to raising the minimum remuneration to a certain level. To the public there is free choice of practitioner. It is merely sought to ensure that, when a practitioner is engaged to perform a particular service, he shall not be paid less than a certain amount." It may be argued that in some cases the minimum is set too high, but it is a legitimate claim and a useful thing to attempt to fix minimum terms, to do this by collective bargaining, and to enforce it by joint action through an organization. When a professional organization has reached a certain stage a further motive and object appears—namely, to see the profession fully and adequately used wherever it can be of service to the State or others. "The advancement of the status of the profession and the extension of the craft in the public interest do on the whole go together"; and "a further development takes place when the State turns to professional associations for advice and assistance." Professor Carr-Saunders goes on to examine the charges against professionalism, which amount to this—that "whatever may be the declared objects of professional associations, in actual practice conservatism of outlook as exemplified by animosity against new methods, selfishness as illustrated by exclusiveness and by interest in status and remuneration, and rigidity of practice as shown by professional etiquette are predominant." These, when investigated, are found to be based upon misunderstanding or upon a perverse insistence on some admitted defects. The nature of the defence has been indicated, and is further explored. Lastly, Professor Carr-Saunders considers the future of the professions, the propriety of any professional register, and the desirability or otherwise of complete or some degree of closure to unregistered persons. He concludes that, as properly defined, there must be an extension of professionalism for commercial and industrial purposes. "Professional associations have something to offer towards the solution of certain of the problems which face commercial corporations. Towards the solution of the problem of efficiency they offer the ideal of adequate qualifications being demanded of those who undertake specialized functions. . . . Taking all in all, the growth of professionalism is one of the hopeful features of the time. The approach to problems of social conduct and social policy under the guidance of a professional tradition raises the ethical standard and widens the social outlook."

#### EDUCATION COMMITTEES AND THE SALARIES OF MEDICAL OFFICERS.

It appears from the programme for the forthcoming annual meeting of the Association of Education Committees at Bath that a motion will be submitted on behalf of the executive committee in the following terms: "That this association protests against the action of the Ministry of Health in withholding Government grant from local authorities if the demands of the British Medical Association are not conceded. The association objects strongly to such a decision being arrived at without previous agreement with the local authorities concerned." It is no part of our business to defend the actions of the Ministry of Health, but this motion appears to indicate a wilful misunderstanding of the position. The adjective is justified by the fact that in the *Supplement* to our issue of January 28th last we published an article on the subject, in which it was explained that some scale of minimum commencing salaries was agreed by the Ministry of Health to be necessary, as both the Ministry and the British Medical Association, as well as local authorities, had found that the public

health service was not attracting medical practitioners of the right qualifications and status. It was explained further that the present scale does not represent the "demands of the British Medical Association," but is a modified scale (in many respects lower than that originally suggested, and leaving a good deal of latitude, within limits, to local authorities), arrived at after consultations between representatives of the Ministry of Health, of the Association of Municipal Corporations, of other associations of local government authorities, and representatives of the British Medical Association and of the Society of Medical Officers of Health. The scale received in general the support of the Ministry and of the Association of Municipal Corporations. Our article further set out that an offer of conference with the Association of Education Committees (*inter alios*) with a view to modifications of the scale then proposed had been refused by that association; and that an offer by the British Medical Association to agree to an appeal committee consisting of representatives of the medical profession and of local government authorities, with a representative of the Ministry of Health as chairman, with a determining voice, was turned down by the Association of Education Committees and by the County Councils Association. We have no knowledge as to whether the Ministry has actually withheld grant from any local authority on the ground that the scale has not been complied with; but it is true that the scale is now operating in more than 82 per cent. of the vacancies occurring in the public health service, and that among the remaining 18 per cent. there are a number of instances in which the local authority is carrying on its service by means of temporary expedients only. In these circumstances there would seem to be an element of perversity in the action of the executive committee of the Association of Education Committees, which might perform a more useful public service by frankly accepting the principle of a scale of minimum commencing salaries for public health medical officers, and either consenting to the establishment of a conciliation committee for cases referred to it on either side, or making practical suggestions for some reasonable modification of the details of an accepted scale. Such suggestions would certainly receive courteous consideration.

#### A TEST FOR PREGNANCY.

ALL will agree with Dr. A. C. Siddall<sup>1</sup> that a simple and satisfactory test for the presence or absence of pregnancy would be most valuable, not only to the obstetrician, but also to every general practitioner. He remarks that at present perhaps the best-known test for pregnancy is that of Aberhalden, but he agrees with Smith and Shiploy, who tried to bring it within the realm of practicability, and concluded that it is of no value for the diagnosis of pregnancy. He mentions the verdict of De Leo that the epinephrine-glycosuria test, Kammtzer's phloridzin test, the dextrose test, and Fahracs's red blood cell precipitation test are merely of academic interest, and also the statement of Hunt and Long that no laboratory method has yet been devised which is absolutely and infallibly diagnostic of the presence or absence of pregnancy, with the exception of radiological examination in the later months. Experimental work in this field has been hitherto dominated by two ideas—namely, that pregnancy causes a specific protein (ferment) to appear in the maternal blood, and that during the early months of gestation there is a tendency to glycosuria. Siddall suggests a test, however, which is based on a different idea from these. Early in 1926 he advanced the hypothesis that if the enlargement of the uterus and breasts of a pregnant woman is due to the

<sup>1</sup> Siddall, A. C.: A Suggested Test for Pregnancy, based on the Action of Gravid Female Blood Serum on Mouse Uterus: Preliminary Report. *Journ. Amer. Med. Assoc.*, February 4th, 1928.

presence of a hormone in the circulation, then corresponding changes should occur in the uterus and breasts of a test animal which had received injections of blood from the pregnant female, whereas the blood from non-pregnant women should give negative results. Binz, in 1924, had observed that, after injecting female mice with the blood of pregnant women, a transverse enlargement of the mouse's uterus resulted, and this result was confirmed towards the end of 1926 by Trivino and Fels. Franek and his co-workers, in a series of papers dating from 1926, have also demonstrated the presence of the female sex hormone in the circulation, not only during pregnancy, but also during the menstrual periods. These results seem to indicate that the blood of non-pregnant females might also have some effect on the uterus of the test animals. Siddall's observations, however, show that this is so small as not to invalidate his method as a test for pregnancy. His test animals were immature non-castrated virgin female white mice of less than 20,000 mg. weight. One cubic centimetre of the patient's blood serum is injected subcutaneously into an immature virgin white mouse once daily for four or five days. On the sixth day the animal is killed, the weight of the mouse is divided by the weight of the uterus plus ovaries, and the resulting ratio provides the criterion for a positive or negative conclusion, a ratio below 400 being positive and a ratio above 400 being negative for pregnancy. Fifty-seven patients were submitted to this test, of twenty-six pregnant patients, twenty-five gave a positive mouse test, while of nineteen non-pregnant patients eighteen gave a negative mouse test, and twelve were incomplete cases. Such evidence requires confirmation in a larger series of patients with controls, and it is to be hoped that further information will be forthcoming.

#### CARDIAC MALFORMATIONS AND ENDOCARDITIS.

If malformations arise in the development of an organ, disease either in that part of the body or in closely related systems is a common sequel. Instances of this process are not far to seek. Congenital defects of the bowel or mesentery frequently conduce to acute abdominal conditions; a misplaced kidney or an aberrant artery of supply may be the first cause of hydronephrosis and ultimate destruction of the organ; and congenital stenosis of the pulmonary artery only too often results sooner or later in pulmonary tuberculosis. The recent work of Clere and Lévy<sup>1</sup> has shown that congenital heart disease is responsible for many of the recorded cases of heart-block in young subjects, while French workers also have been the chief advocates of the view that pure mitral stenosis such as occurs mostly in women without any history of acute rheumatism is due to a congenital cardiac defect which has gradually increased. Although infection of the endocardium is generally regarded as a sequel of valvular deformities as distinct from other defects, it has been shown by Horder, who in 1909 described illustrative cases, that infective endocarditis may arise in conjunction with either a defective interventricular septum or a patent ductus arteriosus. The same writer, in his Lumleian Lectures<sup>2</sup> two years ago, directed attention to the minute structure of the cardiac valves, particularly of the aortic cusps, stressing the likelihood that slight congenital abnormalities might be important predisposing factors in infective endocarditis. Numerous observers over many years have remarked upon the increased incidence of this disease upon congenitally abnormal valves, but that this doctrine represented at best only a part of the truth became apparent in the years immediately following the war, when it was found that infective endocarditis in a subacute form was taking 80 per cent. of its victims from among the most robust

men who had served an average of three years in the most strenuous military occupations. Conversely, although this disease in civilian life was known to be preceded in perhaps half the cases by chronic simple endocarditis, few of the many soldiers at home or overseas presenting minor valvular lesions developed the so-called endocarditis lenta. With the aim of elucidating the part played by congenital abnormalities in the production of endocardial infection, Gladys Wanchop<sup>3</sup> has collected from the London Hospital records fifty-two cases of bicuspid aortic valves and nine of pulmonary valve defects. The latter were found to be commonly combined with more severe congenital lesions, and did not in themselves conduce to endocarditis. Among the infections of the aortic group rheumatic endocarditis occurred five times, in each case affecting the abnormal valve, while the mitral was affected four times; in rheumatic endocarditis generally the incidence is greater on the mitral valve. Infective endocarditis was the cause of death in seven cases; except in one case, where the tricuspid valve only was involved, the abnormal aortic valve was the one attacked. These records brought to light, therefore, an incidence of 11.5 per cent., as contrasted with the estimate of 23 per cent. by Lewis and Grant. The latter figure is comparable, since additional predisposing factors were present in some of the cases. While interest centres principally upon the liability of bicuspid aortic valves to infective endocarditis, it is noteworthy that in the series under review rheumatic infection, fibrosis, atheroma, and calcification were found rather more often than in anatomically normal valves. Less than half of the patients lived more than forty years, but, on the other hand, the fifth decade showed a higher mortality than any other. The important deduction from these observations is that a bicuspid aortic valve does predispose to infective endocarditis, and the findings of earlier investigators go to show that other minor cardiac defects, congenital or acquired, are likewise etiological factors. Since physical strain is clearly at times an activating agent, its prevention would seem to be an important prophylactic measure in those whose hearts show signs of endocardial abnormality. Because it is obvious that some individuals with valvular defects are attacked while others remain immune, it would be a valuable advance in clinical medicine if a means of distinguishing the two groups could be found. Identical organisms may in some cases of infective endocarditis be isolated both from the blood and some source of sepsis in the body. The careful eradication of any possible focus is therefore an imperative prophylactic measure in those who possess congenital or acquired endocardial defects.

#### THE GENERAL MEDICAL COUNCIL'S SESSION.

THE General Medical Council completed its session by sacrificing the whole of Bank Holiday to the hearing of disciplinary inquiries. Our report of the proceedings is continued in this week's *Supplement*. Had the Council adjourned over Whitsuntide, as on a previous occasion, and assembled again at a later date, it would have incurred an expenditure of some hundreds of pounds for railway fares, and with a decrease of revenue from registration fees, and income tax to pay, the Council finds itself obliged to cultivate strict economy. The disciplinary inquiries were unusually numerous, but in the result only three practitioners had their names erased from the *Medical Register*—one for conviction for a felony, another for committing adultery with a married woman with whom he stood in professional relationship, and a third for maintaining, also during professional relationship, a friendship of an improper character with a married woman. In two other cases—two arising out of convictions for drunkenness and the

<sup>1</sup> *Ann. et. Mém. Soc. Méd. des Hôp. de Paris*, March, 1928, p. 490.

<sup>2</sup> *British Medical Journal*, April 3rd, 10th, and 24th, 1926.

<sup>3</sup> *Quart. Journ. Med.*, April, 1928, p. 383.

other out of advertising to attract patients—the facts were proved, but judgement was suspended until a later session. In two cases the charges were found not proved, and in one other, although the facts were proved, mitigating circumstances were allowed, assurances accepted, and the case dismissed. Whatever may be said about the disciplinary work of the Council, the severest critic cannot deny its expeditiousness. Few courts of law could have disposed of so much difficult and delicate business in six days. Another thing to be said is that no practitioner appearing before the Council is prejudiced because he is not legally represented. It conveys no reflection on the legal profession that while all three practitioners whose names were erased were represented by counsel, two of the three who were successful in their defence had neither counsel nor solicitor. Certainly no one will dispute the advantage of legal representation; if it does not affect the result, at least it shortens the hearing. But the point is that the Council is indulgent to the practitioner who appears on his own behalf. A feature of recent sessions has been the increase in the number of cases in which the charge is that of committing adultery during professional relationship. The Council applies no rigid rules to these cases, judging each one, properly, on its merits. The session was remarkable for the appearance of a dentist against whom it was alleged that he had taken advantage of his professional position to commit adultery with a married woman. The professional relationship was denied by the practitioner, but the Council upheld the findings of the Dental Board and directed that the name should be erased. A sad circumstance marked the end of the Council's session. On his way back to Edinburgh a very respected member of the Council, Sir James Hodsdon, died in the train. He had spoken more than once in the Council on the day preceding his death. We hope to publish an obituary notice in an early issue.

#### HISTORICAL EXHIBITION AT CARDIFF.

It is a debatable point whether men are most interested in the very new or the very old; the attitude of the lay press and the public towards such things as the discoveries at Luxor and the excavations at Pompeii seems to suggest that there is an archaeological streak in most people. Tut-ankh-Amen had his day "in the news" equally with Lindbergh and Adolpho Menjou. It may be anticipated, therefore—since medical practitioners are constituted much as other men—that a widespread interest will be taken in the historical exhibition which it is proposed to arrange in connexion with the Annual Meeting of the British Medical Association at Cardiff in July next. It is intended that the exhibition should be specially illustrative of Welsh folk-medicine, which, as in other Celtic countries, has a long lineage, rich in tradition and in history, from the days when the Druids, among the various orders of learned men, practised medicine and magic. An account of some of the outstanding manuscripts and relics relating to Welsh folk-medicine was published in the *Journal of March 24th* (p. 509), and in the same issue there appeared a letter, signed by the President-Elect and others, asking for assistance, notably from practitioners resident in Wales, in the collection of articles suitable for this exhibition. The enterprise is being promoted by the officers of the History of Medicine Section, with the co-operation of the authorities of the National Museum of Wales and the National Library of Wales. Information regarding the theory and practice of folk-medicine, human or animal, and regarding the existence and ownership of illustrative objects, will be welcomed by the organizers. Communications should be addressed in the first instance to the Honorary General Secretary of the Annual Meeting, Dr. G. I. Strachan, 20, Windsor Place, Cardiff.

#### A SURGICAL OUTPOST IN THE HEBRIDES.

##### EXTENSIONS AT THE LEWIS HOSPITAL, STORNOWAY.

IN the extreme north-west of the British Isles, forming a curved breakwater which shelters the mainland from the North Atlantic, lie the Outer Hebrides—a region desolate yet picturesque where, in the phrase of the country, "The sea is all islands and the islands are all lochs." The most northerly part of the chain—Lewis, and its appendage Harris—contains most of the population. On the east coast of Lewis, some six hours' steaming from the mainland across the tempestuous Mince, is Stornoway, the leading town in the islands and the centre of the herring industry. The formal opening there on May 10th, by Dr. Walter Elliot, Under Secretary of Health for Scotland, of an extension to the Lewis Hospital, mentioned in the *Journal* on May 12th (p. 821), marked the inauguration in its complete form of a surgical service for the Outer Hebrides, which was begun in 1924 by the appointment of a consulting surgeon by the Scottish Board of Health. The development of this service is of more than local interest, for it is a departure in State medicine which may well have important effects in the organization of the profession throughout the country.

To explain the origin of the scheme it is necessary to go back to the commencement of national health insurance. When this came into operation it was realized that in the remoter parts of the Highlands most of the adult population would not come under the system; crofter-fishermen could have no status as insured persons as they received no wages. In addition, the supply of doctors was limited. The Highlands and Islands (Medical Service) Commission, 1912, issued a masterly report which analysed the entire medical requirements of this unique area. As a result of its recommendations an increased number of medical practitioners were appointed, district nurses were provided, and it was contemplated that, when funds should suffice, improved hospital and dental services would be instituted. The war delayed the fulfilment of these conceptions, but in 1924, with the appointment of consulting surgeons for Lewis and for Shetland, the first stage of a complete surgical service for the Highlands was begun.

The Board of Health's nominee for the surgical post in Lewis, Mr. J. Ewart Purves, F.R.C.S., by arrangement with its managers, was made superintendent of the Lewis Hospital, Stornoway. This institution was founded by public subscription in 1896, and after an extension in 1912 contained some twenty beds. Both in staffing and in the character of the work done it was, however, essentially a cottage hospital. The people of the island (who number nearly 35,000) had a great repugnance to the idea of going to hospital; institutions were regarded as the last refuge of medical treatment, and the removal of a patient as a severe aspersion upon the humanity of his relatives. The doctor who recommended it was taken as giving a hopeless prognosis, and his advice was followed by lamentations from the patient's friends. In fact, the situation was much the same as that in the cities fifty years ago. Under the old régime the Lewis Hospital was not used to anything like capacity, and frequently it had no patients at all. A prevailing belief in those days was that there was no need for a modern hospital system. It was argued that the simpler habits of this pastoral people of crofter-fishermen exempted them from the morbid conditions of the large centres, and that apart from the services of the practitioner (who still has in one parish some five thousand people to look after) no specialized aid was necessary.

##### The New Hospital Arrangements.

Within a few years the whole situation has changed. The presence of a surgeon consultant and the existence of a modern hospital has produced a supply of surgical conditions for treatment, and even with the institution working at full pressure there are as a rule two patients on the waiting list for each bed. Compared with the swollen queues which line the waiting rooms in the city infirmaries

this may seem insignificant, but many of the island patients have waited long periods even before consulting their doctors. With modern appliances available the number desiring admission is increasing greatly.

When the surgeon was appointed it was realized that for the larger needs of a surgical clinic x rays and other diagnostic aids were essential, and at the same time the increased staff and more efficient management called for greatly improved quarters. With Treasury assistance, the Board of Health authorized the managers to proceed with a scheme for enlarging the hospital and adding certain necessary items of equipment. This extension is now complete and the building has been transformed from a small cottage hospital into a modern clinic—scientific, workable, and compact. It has not been found possible at present to increase very greatly the number of beds; there are now twenty-four, and four cots.

The new wing contains a larger kitchen and greatly improved quarters for the nursing and domestic staff. Owing to the exposed situation of the building a steam heating system has been found necessary. An oil engine with dynamo and batteries gives current for lighting and x rays. The x-ray equipment consists of a "universal" couch which can be moved into any position for screening and photographing, and Philip's "metalix" tubes of fine focus. There is a Potter-Bucky diaphragm, and the whole outfit consumes 5 kilowatts. The apparatus is housed in a commodious room at the end of the building, with ventilating fan, annexes for developing, dressing rooms with shower-baths and lavatories. The National Physical Laboratory has certified the entire system. There are two mercury vapour lamps for general irradiation, and appliances for both local and general diathermy are installed. An enlarged and modern theatre replaces the former cramped operating room, and a laboratory of adequate compass will make clinical research more convenient than before. Under the present arrangements the medical officer of health acts as anaesthetist when necessary, and the whole forms a complete surgical unit. The general experience of cases is said to be similar to that in one of the large infirmaries twenty years ago, and some conditions are seen in a very advanced form reminiscent of the older textbooks.

Figures of the hospital work for two periods—before and after the appointment of the surgeon—illustrate the great change which the institution has caused in the medical practice of the island. For the ten years prior to 1924 an average of seventy patients were admitted each year. In the first whole year of the new surgical service, before the extensions to the building and the installing of the x rays, 376 patients were treated and 375 operations performed. In this period, too, there were over 1,000 out-patient consultations—an entirely novel branch of the hospital's activities. Patients are seen upon the recommendation of their doctors; surgical cases form most of the admissions, although others are not refused. About one-third of the admissions are cases of emergency.

Eye cases which require operation are sent to the mainland. Abdominal work forms a major part of the clinical material, and it is noteworthy that pneumococcal peritonitis is unusually common here in children. Malignant disease, unfortunately, is seen in the later stages, and gynaecology is a large field of practice which is at present unexplored. Cases of difficult labour are beginning to appear upon the hospital list, and the small private ward in the extended institution will thus prove useful. In former days the treatment of tonsils and adenoids in children as recommended by the school medical officer was rarely undertaken, but this is now an important part of the work among children.

#### Communication Difficulties.

The idea of medical practice which prevails in Lewis is one which is largely coloured by the times, here not very far distant, when there were only two medical men to undertake the whole work of the island, and they travelled on horseback many miles over their professional domains at infrequent intervals. In those days each doctor was literally a consultant, in that he was only summoned when the illness had resisted the efforts of the local wise men. Seventh sons enjoyed peculiar prestige in the healing art. In each district even to-day there is some person who is regarded as having special skill in treating fractures and deformities. At the present time, although each

parish has its competent doctor under the Highland medical service, the old traditions linger and it is not unusual for a doctor to be asked to visit a serious case only once in its currency. There are no telephone call boxes or regular means of communication, and the doctor is sent for by telegram, except at night, when some neighbour may set out to track many miles over the moors. In such circumstances the work of a surgical specialist is not easy; there is a tendency for cases to be sent in for operation only as a last resort.

It is difficult for a doctor whose practice lies in, say, some pleasant suburb of Surrey, to contemplate how he would feel if cut off from his friends by a thirty hours' journey from the mainland (including six hours' steaming over a villainous stretch of water), with no opportunities for medical discussion, no colleagues on the telephone, no opportunities for seeing other men's operative work. The city surgeon stops into his theatre and finds all prepared. His mind is freed from extraneous considerations; his sole concern is with the details of his operative technique, and his responsibility may be lightened by collaboration with specialists. But the work of his colleague in the Hebrides is more varied and strenuous. First the patient must be seen and any necessary diagnostic test performed. The surgeon may then have to spend half an hour in persuading the relatives that operation in, say, a perforated gastric ulcer, is a matter of urgency. Having once decided to operate he must arrange for the theatre—perhaps the water supply will be off—to be made ready and go out to find an anaesthetist. (None of the medical men in the island have the telephone.) This has proved so difficult in some cases that local and spinal anaesthesia have been developed and are now utilized whenever possible. Details which in most mainland hospitals are hardly noticed assume here great significance. Success in such a field is achieved only at the cost of much effort in ways which do not fall strictly within the realms of surgery. On one occasion an operation was performed under novel circumstances. At night-time and on Sundays all the telephone lines are connected to the lighthouses at various points around the coast. A message was received from one of these that the surgeon was required for an urgent obstetrical case. Within half an hour his car was on the road with anaesthetist, trained sister, and operating equipment. After a journey of more than fifty miles over some of the roughest country in Britain, including a gradient which is notorious, half an hour's sea-crossing, and a few miles' walk over the moors, the patient was reached, and a craniotomy performed successfully within three hours of the original telephone message. It is a sad comment upon a conflict of bureaucratic interests that on this occasion the telephone was used irregularly. The correct procedure would have been to wait until Monday morning and send a telegram!

#### A Threefold Success.

In a great measure, the conspicuous success of the service must be ascribed to the confidence with which the surgeon has come to be regarded. The idea of anaesthesia is now taken with more composure, and patients appear demanding operations for the most unusual conditions. To an observer this undoubted triumph is the more interesting, as from the very first it was the determination of the present surgeon never to be content with less than the highest pitch of efficiency in nursing, equipment, and his own efforts. His policy has been justified by results. It must be rare that such a campaign of practical education has achieved its aim in so brief a period. The successful establishment of the service here outlined is a threefold triumph. Politically, it reflects departmental continuity in the best sense—the surgical needs of the Highlands were first realized by a Liberal administration before the war; the first surgeon was appointed under the Labour Government; the grant for the further extensions to the Lewis Hospital was made under the present Conservative regime. It is also a demonstration of our professional adaptability, and shows that the influence of the State need not have a sterilizing effect. Lastly, it is a personal victory for the surgeon who has carried an idealist conception successfully into the region of fact.

## Ireland.

### Royal College of Surgeons: Charter Day Dinner.

A LARGE and distinguished gathering was present at the Charter Day dinner of the Royal College of Surgeons in Ireland, which was held in the College, St. Stephen's Green, Dublin, on May 19th, with the President, Mr. Andrew Fullerton, C.B., C.M.G., in the chair. The toast of "The King" having been honoured, the President proposed the health of the Governor-General, and expressed the regret of all present at the reason for his Excellency's absence that night, and their hearty wishes for his speedy and complete recovery. Proposing the toast of "Prosperity to Ireland," the President said he might be forgiven for avoiding any reference to the misery and strife and bloodshed which characterized the years which all lovers of the country hoped had passed away for ever. A brighter era appeared to be dawning for the country, North and South, and there were evidences that a sane attitude was being taken by the large bulk of the Irish people, who, weary of turmoil and unrest, were prepared to settle down to peaceful pursuits. Ireland was a magnetic country, as anyone who visited other places and conversed with travellers and sportsmen knew. Lord Glenavy, chairman of the Senate in the Irish Free State, responding, said that the prosperity of their country was bound up with the prosperity of its professions, and on that account, and in the best interests of Ireland, he delighted in hearing that their great College was so prosperous and flourishing. This was a thing, he thought, in which the country should take more pride. He meant not so much the honoured position that, in conjunction with other professions, the medical profession had always held and maintained at home and abroad, but what he thought was too often overlooked was the great reputation which their profession had consistently maintained in its personal integrity and character. Professor R. J. Johnstone, who also responded, said how much he and his colleagues in Belfast felt the gesture of kindness which that most distinguished College had paid to them in electing their old friend the Professor of Surgery in Belfast as its President for last year and for this year. He was glad to hear that their President was upholding during the tenure of his office the best traditions of surgery. The profession in Northern Ireland, he said, although separated from the Irish Free State by a boundary, guarded by stern guardians on both sides, still hoped and prayed and worked for the prosperity of Ireland, and delighted when their colleagues in the South were prosperous. Sir Conway Dwyer, who proposed the toast of "The Guests," said he thought that one of the most useful purposes that the annual dinner served was that it brought to their minds the assurance that that old College held an important place in the esteem and affection of their citizens. The barrier between North and South did not appear to apply to the medical profession, and it was to be hoped that in the future the disappearance of that barrier would be complete. Might he express the pious hope that, although North was North and South was South, yet in the future a happy meeting would take place? He was sure that they all earnestly hoped that a time would come when memories evoked by the name of a certain river might be forgotten, and that that same river would be esteemed only, and mentioned only, as one of the best salmon rivers in the country. The Rt. Hon. James McMahon expressed on behalf of the guests their feelings of regard and esteem for the President. As a fellow Belfastman he felt pride in the manner in which Professor Fullerton had upheld the dignity and lofty traditions of that great College. Dr. R. W. Leslie (Belfast) said that they rejoiced in the fact that the College had chosen a Belfastman as President; the profession in Belfast knew his gifts, his worth, and his work. The Council of the College was to be congratulated on its wisdom in entending facilities to Belfast graduates for obtaining their preliminary examination for Fellowship of the College, and he was certain that as a result a greater number of Northern students would endeavour to enjoy and share in the glorious traditions of that great

College. Sir John Moore, who also responded, said that they were all glad that the vexed question of medical registration had been settled, and he was most anxious that men at present abroad might have facilities, should they so desire, of practising in the Free State, when they retired from service in the British army and navy. He hoped that the present attempt to separate the nursing profession into North and South would not mature; the Queen Victoria's Jubilee Nurses had done splendid work in Ireland among the people, and especially the poor, and he would regard it as a disaster to separate these nurses into two institutions. Lord Glenavy, on behalf of the vice-president and members of the Council of the College, presented to the President a massive silver salver, accompanying the gift by a very high tribute to Mr. Fullerton.

### Provision for Mentally Defective Children in Northern Ireland.

This subject has come before several public boards lately. In the Northern Senate, on May 22nd, it was raised, and the Minister for Education said that the Education Act contained powers for dealing with the education of mentally defective children. It was proposed to hold a conference with the Association of Education Authorities. The question was bound up with that of the provisions required for the care and maintenance of mentally defective persons up to the age of 16. This could not be dealt with apart from the recommendations on the subject contained in the report of the Departmental Commission on the Local Government Administration, which was at present under consideration.

## England and Wales.

### Sheffield School of Medicine Centenary.

THE centenary of the Medical School in Sheffield is being celebrated this year, and it is interesting to record, in the manner of the times, the way in which the inauguration of this institution was announced. In the *Sheffield Mercury* of July 12th, 1828, appeared the following reference to the proceedings a hundred years ago: "On Wednesday afternoon last the first stone of the Medical Institution which is being erected in Arundel Street, corner of Surrey Street, was laid by Dr. Knight, after which the subscribers and their friends partook of a most sumptuous dinner at the Tontine Inn, Dr. Knight in the chair. Several very appropriate toasts and excellent speeches were given during the evening, by which the conviviality of the meeting was kept up till a late hour." Although instruction had been given by individual medical practitioners in Sheffield to their "pupils" for some years before that date the faculty of medicine of the University has selected this year for the celebration of the centenary, since it was in 1828 that a medical school with a corporate governing body first came into being. There, in honour of the occasion, the University will, on Wednesday, July 11th, hold a congregation, at which the Chancellor of the University, the Marquis of Crewe, will preside. Delegates from the medical faculties of other universities and representatives of the city and the University will be entertained at an official luncheon to be given by the faculty of medicine. It is hoped that as many past and present students of the medical school as possible will attend, as well as members of the profession in Sheffield and the district, and others interested in the welfare of the school. In the evening a conversazione will be held in the University, when many interesting scientific and other exhibits will be shown. The faculty is about to publish a history of the Medical School in Sheffield, written at its request by the late Dr. W. S. Porter.

### Post-Graduate Courses in Tuberculosis.

Two post-graduate courses, organized by the Joint Tuberculosis Council, will be given in the summer months, the first at the Lord Mayor Treloar Cripples' Hospital, Alton, Hampshire, from June 25th to June 30th, and the second at Cambridge, from July 2nd to July 7th. The arrangements for the Alton course have been made by the medical

superintendent, Sir Henry Gauvain, who will himself give the greater part of the lectures and demonstrations, and will deal with hospital organization for surgical tuberculosis, heliotherapy in surgical tuberculosis, tuberculosis of the spine, tuberculous adenitis and peritonitis, etc. Dr. Jones will lecture on tuberculosis of the hip, and Mr. Duke-Elder on tuberculous disease of the eye and treatment by ultra-violet light. "Bacteriology in tuberculosis" will be the subject of an address by Dr. Bannerman, and Mr. Fairbank will speak on differential diagnosis of bone and joint lesions. In the course of the week there will be a demonstration by Dr. Wood at King George's Sanatorium, Bramshott, including light treatment in adults, and the closing day will be given up to a demonstration at Sandy Point, Hayling Island, illustrating sea-bathing as a therapeutic measure.

The programme for the Cambridge post-graduate course has been arranged by Dr. P. C. Varrier-Jones, and an inaugural address will be given by Sir Humphry Rolleston, Bt. Professor J. B. Buxton is to provide a demonstration on tuberculosis, Professor G. H. F. Nuttall a demonstration of parasites, and Dr. G. S. Graham-Smith a lantern demonstration on flies. "Chemotherapy and the tubercle bacillus" and "The mental factor in tuberculosis" will be the subjects of lectures by Professor W. E. Dixon and Dr. J. T. MacCurdy respectively. Dr. W. Paton Philip is to speak on the diagnosis of pulmonary tuberculosis, and Dr. Louis Cobbett will discuss the influence of diet on the decline of the disease. An all-day visit will be made to the Papworth Village Settlement, under the guidance of Dr. Varrier-Jones, medical director, and at the closing session on the morning of Saturday, July 7th, Professor H. R. Dean will demonstrate the anatomical and microscopical changes present in tuberculosis. Information regarding the courses may be obtained from the Honorary Secretary, Joint Tuberculosis Council, Post-Graduate Courses, The Larches, Farnham Royal, Bucks.

#### Proposed Child Guidance Clinic for London.

An offer has been made to the London County Council by the Child Guidance Council for the establishment of a child guidance clinic in London to which maladjusted or delinquent children could be referred with a view to the establishment of harmony between the child and his environment. Clinics of this type are already established in Canada and the United States. The London Education Committee, in considering the proposal, points out that the idea is not altogether new, and has been carried out in London and elsewhere increasingly of recent years. Special schools, were first of all instituted for children suffering from physical disabilities, then for the mentally defective, with special classes for the dull and backward. In the matter of delinquent children, it has been the custom to obtain reports from special officers, care committees, and others, to arrange for special examinations by the school medical officer, and perhaps by the psychologist employed by the London County Council, and in this way the juvenile court receives assistance, as also does the superintendent of any residential school to which such children may be sent. Altogether, as much child guidance work is carried out in London as in any city in the world, though it has not been organized as formally as in some parts of America. Under the American plan the full history of the case is obtained to enable those working with the child to have a clear picture of the conditions under which he has lived. A report describing the work of a typical school guidance clinic (at Cleveland, Ohio) was laid before the Education Committee by Dr. Letitia Fairfield, who states that the great feature of the American work is the staff conferences on each case. At these the various clinic officers who have examined the case, representatives of the referring agencies, and perhaps the school teachers, may be present; comments are made, and a plan is drawn up for treatment, sometimes an elaborate one if family complications are to be relieved and harmony restored among an excitable group. Dr. Fairfield reported that "in view of the very lively dread of psycho-analysis in certain quarters, it may be said here that I did not find anything approaching analysis being carried out in

any clinic. Most of the staffs were not Freudians, but behaviourists, and even in the few cases where the psychiatrists belonged to the analytic school they did not think the procedure suitable for clinic conditions." The Education Committee is recommending to the Council that the offer of the Child Guidance Council for the establishment of a clinic be accepted, subject to certain conditions, that as an experiment for three years it be recognized as a school clinic, that children be referred to the clinic by the school medical officer, subject to the consent of their parents or guardians, and that visits to the clinic by the medical staff of the London County Council be allowed at any time.

## Scotland.

#### Gifts to Scottish Hospitals.

Two substantial money gifts to Scottish hospitals, both for the endowment of maternity institutions, have been announced recently. At the opening by Lady Chamberlain, on May 17th, of a new nurses' home at the Glasgow Royal Maternity Hospital it was intimated that Mr. Archibald Walker of Newart Castle, Ayr, had given a sum of £40,000 for endowment purposes to the hospital. The directors of the Dundee Royal Infirmary were informed at a recent meeting that for the further endowment of the new maternity hospital Mr. F. B. Sharp, a Dundee manufacturer, who resides at Cupar, in Fifeshire, and his sister, Miss Christina Sharp, had given annuity bonds of £14,000 and £6,020 respectively. Last year the two made an endowment gift of £28,000, and two years ago Mr. Sharp, with his brother, the late Mr. R. B. Sharp, gave £30,000 to build and equip the hospital.

#### Edinburgh Hospital for Sick Children.

The annual meeting of the Royal Edinburgh Hospital for Sick Children was held on May 8th. Mr. Colin M. Black, W.S., chairman of directors, who presided and moved the adoption of the report, referred to the fact that the hospital was unable to meet out of ordinary income the ordinary expenditure incurred in the hospital and convalescent home, and that legacies and special donations had to be used in the past year to make up a balance of £5,750. The report records the receipt of legacies in the past year amounting to £8,840. With regard to the patients treated, the average daily number during 1927 was 114 and the average duration of residence 17 days. The total number of patients treated in the wards and in the out-patient department was 38,803, compared with 33,354 in the previous year. In the hospital 1,106 operations had been performed, and in the out-patient department 1,395 minor operations. A special feature had been the artificial sunlight department, where the total number of treatments had been 8,919, as compared with 2,688 in 1926. In the ear and throat department attendances had numbered 2,439, as compared with 2,106 in the preceding year. Attention is drawn in the report to a special study which is at present being conducted by the hospital into the problem of rheumatism in childhood and adolescence, especially in regard to the production of cardiac disease.

#### Central Midwives Board for Scotland.

At the recent examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, there were 129 candidates, of whom 121 passed. Of the successful candidates, 20 were trained at the Royal Maternity Hospital, Edinburgh, 55 at the Royal Maternity Hospital, Glasgow, 10 at the Royal Infirmary, Dundee, 4 at the Maternity Hospital, Aberdeen, 5 at the Queen Victoria Jubilee Institute, 7 at the Elsie Inglis Memorial Hospital, 2 at Stobhill General Hospital, 3 at Belshill County Hospital, 2 at the Cottage Nurses' Training Home, Govan, and the remainder at various other institutions.

## Correspondence.

## MYCOSES.

SIR,—With reference to Dr. Rupert Hallam's interesting paper on mycotic infections of the hands and feet in your issue of May 19th, I should like to be allowed to emphasize the extreme frequency of these infections in the tropics, and in general in all countries with a warm moist climate, such as Louisiana and Mississippi in the United States, certain parts of Southern Italy, Spain, and the Balkans. In New Orleans more than 30 per cent. of the medical students suffer in the late spring and summer from epidermophytosis of the toes. The condition has, of course, been known for years in Ceylon, Southern India, Singapore, and Hong-Kong, where it is known by a variety of names—"mango toe," "Hong-Kong toe," "Cantlie's foot-tetter," etc.—and a description of it was given by Chalmers and myself in our *Manual of Tropical Medicine*. It is caused, as proved by Sabouraud and Whitfield, by the same fungi that cause ordinary dhobi itch (*tinca cruris*, *tinca inguinalis*), the principal species of these fungi being *Epidermophyton cruris* Castellani, 1905 (synonym, *Ep. inguinalis* Sabouraud, 1907), and *Epidermophyton rubrum* Castellani, 1909. Both these organisms were first found and described by me in Ceylon in cases of dhobi itch. They are also the causative agents of certain cases of mycotic pruritus ani.<sup>1</sup>

I should like to call attention to another as yet little known mycosis which is far from rare in the tropics and in temperate zones, including this country, but is often overlooked—namely, furunculosis cryptococcica vel moniliacea (pyosis cryptococcica vel moniliacea). I described this condition several years ago,<sup>2</sup> and recently I again gave a description of it in the Gehrman Lectures on mycoses, delivered by me before the University of Illinois, and published in the *American Journal of Dermatology and Syphilology*, February, 1928 (p. 205).

The condition clinically is often indistinguishable from ordinary furunculosis, the patient presenting on various regions of the body lesions identical with ordinary boils. It runs an exceedingly chronic course. In some cases the scalp is principally or solely affected (folliculitis decalvans cryptococcica). In these latter cases the eruption usually begins as a follicular pyosis of the scalp, each pustule being pierced by a hair. The pustules may be somewhat flattened or conical; in addition to the pustules there are often fairly large infiltrated patches which later on open and discharge through several openings like carbuncles. The hair in the affected areas falls off, and patches of baldness, at times permanent, may be seen.

Pyosis cryptococcica responds very satisfactorily to potassium iodide given in full doses, but not to staphylococcus vaccines. I shall be glad to supply workers interested in the subject with cultures of the fungi I have isolated from various cases.—I am, etc.,

ALDO CASTELLANI.

Ross Institute and Hospital for Tropical Diseases, London, May 22nd.

## THE TREATMENT OF MALIGNANT DISEASE BY COLLOIDAL LEAD.

SIR,—The report of Dr. Stanley Wyard on this subject, published in the *British Medical Journal* (May 19th, p. 838), is a highly significant, indeed a surprising, document, and as such calls for some comment from me. Certain past events into which I need not now enter make it a matter of strange taste for Dr. Wyard to have entered the field of criticism in regard to our work, and it may be doubted, in view of his own statements, whether Dr. Wyard ever seriously attempted to give the treatment a fair trial. Alternatively, or as well, we must question his clinical and scientific acumen, for a more unscientifically conducted investigation on which to base conclusions to the discredit of our work could hardly be conceived.

<sup>1</sup> *British Medical Journal*, December 1st, 1925, p. 1037.

<sup>2</sup> See *Journ. of Trop. Med. and Hygiene*, December 1st, 1924.

1. Why did Dr. Wyard use lead hydroxide after all our warnings to the contrary? True he does not include the cases so treated in his table of results; but the impression produced on the mind of an impartial observer, let alone that of Dr. Wyard, would have been deplorable. No doubt his views concerning the danger of the method were largely inspired by the effects following the use of a very toxic material.

2. The method of preparation of the so-called "colloidal lead" administered by Dr. Wyard, which he would have his readers believe was similar to our own, is grotesque. As I do not consider it necessary at the present juncture to discuss the full extent of his errors in this respect, I will merely remark that "shot" are not composed of pure lead, but contain what is believed to be an activator (arsenic) of malignant growth. This may surprise Dr. Wyard; nevertheless, it is a fact. What a poor return for the efforts of Professor Lewis and his associates in 1926 to teach Dr. Wyard how a lead colloid should be prepared!

3. The statements are made that "Examination of the blood really helps very little," and "We found that the number of red cells showing punctate basophilia was no evidence whatever for or against continuation of treatment"—statements which leave us bewildered. We can only conclude that Dr. Wyard's methods of observation are less refined than those of ourselves and others.

4. On examination of the table of results we note that of 56 patients treated with "colloidal lead" as many as one-half were under treatment for less than seven weeks, and of these, 17 died within that short period. A number—it is impossible to say from the data given exactly how many, but not less than 14 per cent.—died after a single dose. Forty-six of 56 patients did not receive the minimum complete course (0.5 gm. Pb), and 40 of these 46 received less than 0.4 gm. Pb. It is characteristic of Dr. Wyard's methods that, in regard to the only case which appears to have been suitable for treatment, and which has improved to so great an extent as to merit special comment, he should throw doubt on the diagnosis.

As Dr. Wyard draws from this assembly of clinical and scientific errors the conclusion that "there is no support for the statement that colloidal lead exerts a beneficial influence upon the progress of a malignant growth," perhaps I may be allowed to state my own conclusion from the same data—namely, that Dr. Wyard is neither competent to treat cases of cancer with lead nor to express an opinion on this subject.—I am, etc.,

Liverpool, May 21st.

W. BLAIR BELL.

## TREATMENT OF PROSTATIC ENLARGEMENT.

SIR,—I was much interested in the letter from Dr. C. E. Dennis of Melbourne, commenting on mine, published in your issue of April 21st (p. 691) and to note that his experience in the treatment of prostatic enlargement by radiotherapy agrees with mine.

It seems to me a most regrettable fact that British surgeons and practitioners do not recognize the great benefits that x-ray treatments can give in suitable cases. It is the same thing in the field of gynaecology where menorrhagias, metrorrhagias, menopausal haemorrhages, etc., are subjected to curettage, or a major abdominal operation, before radiotherapy has been given the trial that, in suitable cases, is always suggested on the Continent and in America prior to surgical intervention. No x-ray specialist of experience claims that radiotherapy is a panacea for all these conditions, but it is so often successful in effecting a cure that I plead that patients should be given the chance of relief by the simple and painless use of x rays more frequently than is at present the case. Regular consultations between the surgeon and the radiologist, and the mutual recognition by both of the expert knowledge in their own specialty possessed by each, is the only way in which the best interest of the patient can be attained.—I am, etc.,

J. CURTIS WEBB,

Consulting Radiologist, Gloucester  
Royal Infirmary.

Cheltenham, May 21st.

## DEAD AND INFECTED TEETH.

SIR,—In answering some points in Dr. Cowan's letter of May 19th (p. 876) I feel it would be best to confine myself to practical and scientific issues. With regard to instructions sent via the patient, the desirability of entrusting dental cleansing entirely to the dental surgeon's judgement, or, in doubtful cases, of arriving at decisions in consultation with him, must surely be obvious; it is certainly one's own practice to regard a dental practitioner, not as someone to whom "instructions" are sent, but as a colleague to whom one makes courteous requests. The extraction of teeth on x-ray "evidence" alone, and, conversely, their retention simply because of its absence, should be condemned; the widespread and growing subservience to radiography throughout the whole range of medicine and surgery as the supreme and infallible diagnostic instrument is a grave menace to the clinical skill of the rising medical generation.

It is not a surgical heresy to render aseptic a living organ; it is a surgical heresy to retain in the body a mass of dead tissue, difficult primarily of sterilization (vide Dr. Cowan's own admission), and, even if that be temporarily achieved, extremely liable thereafter for ever to infection as a *locus resistencie minoris*. There can be no exception to the principles of the practical application of pathology in however small a branch of the surgical art. I can only urge that the article leading to this correspondence should be re-read.—I am, etc.,

London, W.1, May 22nd.

C. JENNINGS MARSHALL.

## SEA-SICKNESS.

SIR,—Like Dr. Bennett (May 5th, p. 752) Dr. G. H. Orlic<sup>1</sup> has discounted the labyrinthine theory of sea-sickness. He found that a metabolic change was predominant, and that a "condition of acidosis is present before vomiting commences," which gets worse as vomiting sets in and continues. According to him the administration of glucose "causes diuresis, abolition of acetonaemia, and a fall in the ammonia excretion, resulting clinically in the relief of symptoms."

The change in the blood, it seems to me, can only be explained by an impairment of the hepatic function, primary in time. Either the pneumogastric nerve sends down impressions to the hepatic cells, inhibiting them, the reason and mechanism of which are rather difficult to see, or else the impairment is due to a change in the blood flow through the hepatic capillaries, occasioned by fall of pressure in the epigastrium, the result of the sudden descents with the ship pitching. The feeling one has when on board a pitching ship is the queer sensation, experienced especially in the abdomen, of removal of the pressure supporting the body when, after the rise, the ship falls: it is like the beginning of a descent in a lift. Even though changes in the brain occur, tending to cause nausea and vomiting, changes in the abdomen, produced locally, it seems to me, are much more likely to be causal of these visceral symptoms.

In this respect I note with interest the postural treatments advocated by Dr. Bennett, and by Dr. Wright (May 19th, p. 877). In severe cases the former places his patient in a warm salt-water bath for half an hour or an hour or more. "The relief is great and remarkably prompt. . . . The specific gravity of the water is 1020, and the body is supported very lightly." Moreover, the water, in virtue of its inertia, does not respond to the rolling and pitching as does the bath itself. Dr. Wright also advocates warmth and postural treatment. The patient is "to go immediately to a warm and airy cabin and lie on the flat of the back—not the side, remember!" I wonder why the patient must lie on the back and not on the side. Does it affect labyrinthine changes, or does it affect the pressure in the abdomen? It certainly influences the latter, as observations of the pressure in the rectum and in the stomach show that the pressure within the abdomen is greater when lying at ease on the back than when lying at ease on the side. (In the case of the stomach, this holds when the pressure on the back is

compared with the pressure when on the right side; if the patient lies on the left side the weight of the liver comes into play and higher pressures than when on the back are found.)

The efficacy of this postural treatment seems to support the idea that a visceral circulatory disturbance is in play: the effect of administering glucose further supports that conjecture. Glucose, presumably, can have no effect on labyrinthine disturbances; that it greatly helps the liver in its work, especially in states of impaired hepatic activity, we know. Thus we come to the opinion that the hepatic disturbance is due to a diminution of blood flow through the liver, occasioned by the successive sudden falls of intra-abdominal pressure. At first sight, however, it would seem that a fall in epigastric pressure, by decompressing the hepatic capillaries, would result in a greater capillary flow of blood through the liver. But there is evidence which indicates that with decompression of capillary beds a corresponding constriction of the supplying arterioles occurs—limiting the blood supply to the insufficiently supported capillaries, and, conversely, that with increased compression of capillary beds, a reflex dilatation of the arterioles concerned is produced—allowing a greater blood pressure to play upon the capillaries. These, being now more compressed, can withstand a greater blood pressure, and thus, unless the capillary compression is too great, a greater blood flow through the organ or part occurs. The portal vein and its branches are remarkable for their musculature: of what use is this unless to control the blood flow through the liver? That the degree of constriction of these vessels, as that of the hepatic arterioles, is particularly related with the blood pressure within the hepatic capillaries seems to me a reasonable supposition.

—I am, etc.,

Rugby, May 19th.

R. H. PARAMORE, F.R.C.S.Eng.

## PHARYNGO-OESOPHAGEAL SPHINCTER.

SIR,—In your issue of May 19th (p. 879) Mr. V. E. Negus writes to repudiate any connexion with what Dr. Hurst has called "the pharyngo-oesophageal sphincter of Negus." Mr. Negus offers an apology to Professor Chevalier Jackson, implying that that distinguished endoscopist's name ought to be associated with that misnamed sphincter rather than his own. I doubt if Professor Jackson will be flattered, as there is no such structure as a pharyngo-oesophageal sphincter; and it is certainly not synonymous with the crico-pharyngeus muscle, the Continental name for the lower division of the inferior constrictor, the role of which in health and disease was originally elucidated by the late Professor Killian in 1908. Even seven years later, when Professor Jackson published his large work on *Peroral Endoscopy*, he had only partially grasped Professor Killian's views on the action of the lower (that is, the crico-pharyngeal) portion of the inferior constrictor muscle, as he nowhere in that work alludes to the sphincteric function of the crico-pharyngeus, which Killian first so clearly expounded and illustrated.

Neither does Mr. Negus, as far as I am aware, in so many words allude definitely to the crico-pharyngeus as a sphincter. This muscle is, of course, purely a pharyngeal structure—the lowest muscular band—and is the sphincter of the lower end of the pharynx; it is altogether distinct from the gullet, and is not incorporated with the circular fibres of the latter; and, moreover, the pharynx and gullet belong to two distinct types of musculature both morphologically and histologically, as the circular fibres of the gullet are partially of the unstriped variety. What is really, however, to the credit of Mr. Negus is that he has made the suggestive pronouncement that a hitherto unrecognized function of the crico-pharyngeal portion of the inferior constrictor (which Killian called the sphincteric portion) is to keep closed the lower end of the pharynx during inspiration and thus preventing aerophagia—that is, the entry of air into the gullet at each respiratory intake.

Mr. Walter Howarth (May 26th, p. 922) thinks that credit should be given to Sir Everard Home for having discovered the crico-pharyngeus, but I may remind him that the anatomy of the pharynx, including its inferior constrictor muscle, with its two origins from the thyroid

<sup>1</sup> *Lancet*, 1927, ii, 811.

and cricoid cartilages respectively, was taught to students of medicine in Italy and elsewhere centuries before Home. It was Killian solely who taught us the sphincteric function of the muscle and the part it plays in pouches and in functional and other conditions.—I am, etc.,

London, W., May 24th.

WILLIAM HILL.

#### THROMBO-PHLEBITIS MIGRANS.

SIR,—Perhaps a lack of lucidity in my previous letter accounts for Dr. Jeudwine's presentation (May 12th, p. 824) of my statement as an argument against—whereas I had intended it as an argument for—the possible infective nature of thrombo-phlebitis migrans. When I said that most of my cases of pulmonary thrombosis (infarction) occurred in close chronological proximity with cases of such conditions as pulmonary embolism after operation and confinement, I meant that pulmonary embolism, whether it appears during an attack of influenza or after injury, operation, or confinement, has a habit of occurring during the epidemics of what we call "influenza." The inference, therefore, is that influenza or infection is connected with the thrombosis.

Leaving out of account such questions as whether the thrombosis is due to gelation of protein particles, and whether the thrombosis is always *in situ* and is never transferred (embolism), we still have to find out what *initially* causes the blood changes which lead up to the thrombosis; what, in other words, is the "primary condition" of which Dr. Jeudwine speaks. There is only one such definite condition that I know, and this is the presence of heart disease. Thrombosis, however, in the absence of the latter, may occur in any type of patient—last June I saw pulmonary thrombosis in a girl aged 8.

Dr. Jeudwine says that thrombo-phlebitis migrans cannot be regarded as primarily a bacterial infection, and that the true explanation is arrived at by the work of Mr. J. E. R. McDonagh. But surely Mr. McDonagh stated in his article that it is "in all the intoxications and infections" that "some of the protein particles in the plasma . . . undergo hydration." This, then, is no argument against the infective theory.

While I admit that in some cases of thrombo-phlebitis it is difficult to trace the original infection, in other cases the latter is very plainly observed. A few such cases are as follows.

(1) A man, aged 45, had acute tonsillitis; the temperature came down, but three days later there was extensive pulmonary thrombosis with expectoration of a large amount of dark haemorrhagic sputum resembling plum jam. Later jaundice and intense haemolytic anaemia supervened.

(2) A man, aged 37, had acute tonsillitis; he appeared to improve, but five days afterwards dyspnoea and cyanosis came on suddenly; he later spat up dark blood sputa, and subsequently became jaundiced. On the very same day when this man had his pulmonary thrombosis a woman had a pulmonary infarction after ovariectomy. She spat up dark haemorrhagic sputum, and died twenty days later of a second embolism.

(3) A man, aged 28, had acute tonsillitis on February 15th, 1926. Sixteen days afterwards there was otitis media, and on March 10th there was transient "nephritis" (renal thrombosis). On March 30th there was pulmonary thrombosis with characteristic blood sputa. Later there was thrombosis in one arm and intense anaemia.

(4) A woman pregnant for seven months had a pulmonary infarction with characteristic sputa; the initial label was "pneumonia." Thirteen days later I saw a man who, during an attack of influenza associated with a very localized pleural rub, expectorated very light blood sputa, which much alarmed his wife. These two cases occurred during the maximum prevalence of influenza in 1926.

(5) A woman who had influenza during the puerperium (her husband had influenza at the same time) developed a pulmonary thrombosis and expectorated some blood sputa on the nineteenth day.

(6) A woman, aged 39, had a slight attack of influenza before being confined. She died suddenly and unexpectedly on the eighth day of an aseptic puerperium. A partial necropsy disclosed an *ante-mortem* clot in the iliac veins. The chest was not opened, but there can be no doubt as to the cause of death. Eight days later a man aged 23, who had had a cold before operation, had a typical pulmonary infarction four days after operation for hernia. Influenza was again prevalent.

These are just a few cases culled at random. I have notes of many more which, when less experienced, I diagnosed as "pneumonia." I was in those days sur-

prised to find the patients walking out on the tenth day after no more than symptomatic treatment, in which the supply of electrons did not figure.

I have made no reference to the renal, cerebral, and mesenteric thromboses which I always see at the same seasons as I see the pulmonary thromboses. I refuse to believe that their occurrence together in point of time is always a coincidence, and I believe it is to be explained by the effect of some air-borne infection upon the blood.—I am, etc.,

Aberdare, May 14th.

AMBROSE W. OWEN, M.D. Lond.

#### THE "CURE" OF TUBERCULOSIS.

SIR,—Dr. Carswell hints that 0.000000001 mg. H.T.S. is so absurdly small a dose that it could not be effective. Will he give it and the subsequent doses a trial?

The dose of an antigen, as in the case of any other drug, depends on its potency, 0.000000001 mg. H.T.S. corresponds to 0.0001 c.m.m. A.T.; the equivalent dose of a potent streptococcal antigen is one million, approximately 0.0003 mg.

If Dr. Gunter adds to his good work by using autogenous catarrh antigens he will find that he will have to modify his third and fifth conclusions.

I was most interested in Professor Greenwood's paper. About twenty years ago Karl Pearson investigated the statistics of tuberculosis and pointed out that the fall was not as significant as it appeared to be, since the fall in the tuberculosis death rate was not so great as that in the general death rate—in fact, the tuberculosis death rate was tending to rise in its relation to the general death rate. Is this the case now? Some time or other an administrative area will be handed over for the practice of immunization methods of tuberculosis treatment. There will be an inevitable fall in the case incidence and mortality. I should very much like to know from Dr. Greenwood what the proper method of correction of the absolute figures should be so as not to give a false appearance of success.—I am, etc.,

W. M. CROFTON.

University College, Dublin, May 21st.

#### INJECTION TREATMENT OF VARICOSE VEINS.

SIR,—From this distance it is impossible to reply at once to all the correspondence regarding the injection treatment of varicose veins, but the three letters from Dr. Douthwaite, Dr. Ronald Thornhill, and Mr. E. W. Dewey (March 24th, p. 522) can be answered as one.

In the first place I would say that the expense of the oily compounds of arsenic is here not excessive, and even if it were the patients would have no objection to the cost if they cured varices. In my experience there is no danger in their use if the ordinary precautions are taken.

The chief theme of all the letters is to rebut my statement that varices of veins are of syphilitic origin. In my book on pathology it is stated that the diseases of veins are the same as those of arteries. Now only Dr. Thornhill makes out any case as to some other cause for varicose veins. He tabulates the causes as pressure—namely, pregnancy, standing, constriction of the limb (due to a tourniquet, I presume), or similar conditions. Surely Dr. Thornhill is not serious in suggesting that the pressure of pregnancy or constriction or standing is the cause of varicose veins. They may be the determining factor, but never the cause in a healthy subject. Should the varices persist after the "cause" has been removed, then certainly there must have been a predisposing cause, otherwise the incidence of varicose veins during pregnancy would be appalling. The copying by authors of causes of diseases from one book to another without sufficient analysis is well known, and it is only by personal observation with an open mind that one can narrow down the true causes of a disease. Would anyone venture to state that the cause of pneumonia is catching cold if the pneumococcus is not present?

Mr. Dewey's case is quite comprehensible, but an argument drawn from one case cannot be set against a general experience of a large number of cases dealt with and

cured without a single failure. Would it be asserted that I have been unfortunate in meeting only syphilites?

My method is to inject at the very lowest point of the vein below the last varix, and where it is of the vine-branched type to put some of the injection into each branch at the same sitting at the lowest point always. I then bandage the limb, as far as the varix extends, for a few days, when it is found to have vanished. With this I give Hutchinson's prescription for mercury by the mouth for three months. In varicose ulcers I inject below the ulcer with a very fine needle and apply some simple dressing, keeping the leg elevated for fourteen days, when it will have healed up with the formation of a strong scar, which does not again break down.

Treatment by operation or "embolic injections," if I might use the term, throws the burden on to the deeper veins. It has always been acknowledged that the result of operation causes the varix condition of the deeper veins to be exaggerated. By the embolic treatment there is always the fear that a portion of clot may break away, sometimes with fatal results, and there is also the pain which follows the injection.—I am, etc.,

Uppington, South Africa, April 24th.

W. M. BORCHERS.

#### TYNDALL v. ALCOCK.

SIR,—I read Professor E. W. Hey Groves's article on this case in the *British Medical Journal* of May 12th (p. 807), and I certainly fully agreed with it, and have much sympathy with Dr. Arnold Alcock, who seems to me to have done all that any of us have been taught to do in the sort of elbow injury described so graphically by Professor Hey Groves. Mr. P. B. Roth now enters the field (May 26th, p. 921), and, as so often happens in our profession, goes exactly counter to Professor Hey Groves, and I think without reason, because Dr. Alcock never stated that he treated his case with acute flexion of the elbow-joint and tight bandages, etc.

Ischaemic contraction is certainly a very rare accident and requires to be carefully guarded against, of course; but the actual point at issue in Dr. Alcock's case is, Did he, or did he not, exercise every reasonable care in the treatment of the case for which he was brought into court and mulcted in such heavy damages? I maintain, as a hospital surgeon of very extensive experience, that he did all that any of us were ever taught to do in a case of the sort, that the verdict against him has been most unjust, and that as a profession we should do all that can be done to see that he receives fair play.—I am, etc.,

Meath, May 26th.

EDWARD THOMPSON, F.R.C.S.I.,  
Surgeon, Tyrone County Hospital.

#### MEDICAL FREEDOM.

SIR,—Remarks made at a recent inquest by a coroner about a doctor who was supposed to have refused to attend a dying man seem to call for some comment. According to the *Observer* of May 6th:

"Dr. Edwin Smith, the coroner, in returning a verdict of 'death from natural causes,' said: 'I am not at all sure that the General Medical Council should not take up a case of this kind. A doctor is not, it is true, under a legal obligation to go to a person not already in his charge, no matter how urgent, but there is the strongest possible moral obligation when a case is one of urgency.'" (The italics are mine.)

Coroners, under the shelter of their court, frequently give voice to sweeping recommendations on matters fundamentally affecting the State or some of its members, and to some extent get the support of the uneducated part of public opinion. Dr. Smith in this case admits that the doctor's action, if it was as he was told, was neither criminal nor tortious, yet by laying stress on moral obligation he suggests that possibly the General Medical Council might interest itself in this matter, and thus put the doctor under the peril of losing his status as a registered medical practitioner. Although generally no other citizen is forced to practise his profession or occupation, and although at common law the doctor need not, yet Dr. Smith seeks to limit the freedom of the latter by calling into operation the body which governs the conduct of the profession, and thus undermine the principle and wisdom of the common law.

Now doctors are notoriously charitable, and there are very few who would not fulfil, without fear of punishment,

the moral obligation suggested by Dr. Smith—so few, indeed, that limitation of their freedom to sell their labour like anyone else would, to that extent, place the remainder in a position of quasi-slavery, contrary to the spirit of freedom natural to, and so wisely used by, the average Englishman.—I am, etc.,

Warrington, Surrey, May 16th.

W. S. RUSSELL THOMAS.

#### Obituary.

##### HIDEYO NOGUCHI, M.D.

IN the death of Hideyo Noguchi at the early age of 52 medical science has lost one of its most famous research workers. His was a name known to medical men throughout the world, and justly so; for his elaboration of the methods of culture of spirochaetes, particularly those of syphilis and relapsing fever, opened up to investigation fields which had not hitherto been explored.

Born in Japan in 1876 Noguchi was educated at Tokyo University, and at the early age of 25 proceeded to America to take up the post of assistant lecturer in pathology at Philadelphia. Two years later he was appointed research assistant to the Carnegie Institute, and later joined the staff of the Rockefeller Institute. There he acquired for himself an international reputation and brought lustre on this great centre of medical research.

Noguchi's early work on the blood, agglutinins, opsonins, haemolysins, snake venoms, and kindred subjects led him to a study of the serological diagnosis of syphilis, a line of research which culminated over sixteen years ago in his successful culture of *Treponema pallidum*, which spirochaete he shortly afterwards demonstrated to be present in the brain in general paralysis and in the spinal cord in tabes. These observations proved conclusively the syphilitic origin of these diseases. The methods of culture were extended to all known pathogenic forms, in addition to others which are merely saprophytic, like those in the mouth. He paid particular attention to the spirochaete of Weil's disease, many human and rat strains of which he investigated. For this type of spirochaete he introduced the name *Leptospira*, now in general use. In the midst of this work time was found for a study of the virus of vaccinia, it being shown that a bacterium-free virus could be cultivated in the testis of the rabbit.

Noguchi's acquaintance with the experimental side of leptospiral infections led him to Guayaquil in 1918 to study yellow fever, which had long been suspected to be a spirochaetal disease allied to infectious jaundice. There, at the end of 1918, and later in Mexico, Peru, and Brazil, he cultivated from the blood of supposed yellow fever cases a leptospira morphologically identical with that of Weil's disease. A long series of careful serological and animal inoculation experiments convinced him that the organism differed from *Leptospira icterohaemorrhagiae* of infectious jaundice, and regarding it as the long-sought-for etiological factor in yellow fever he gave it the name *Leptospira icteroides*. He even believed that he had transmitted it from guinea-pig to guinea-pig by means of the mosquito vector of yellow fever. A vaccine was prepared from cultures and an antiserum in horses, and reports submitted appeared to indicate that these were protective and curative in outbreaks of the disease. Doubts, however, began to creep in. Other workers could not confirm the serological findings, and in West Africa particularly British workers failed to discover the leptospira. Finally, the West African Yellow Fever Commission of the Rockefeller Foundation, on which Adrian Stokes sacrificed his life, announced the susceptibility of the Asiatic monkey and the absence of leptospira from human cases and that experimentally produced in monkeys. Though fully occupied with investigations on Oroya fever and verruga peruviana, and his recently isolated bacillus from cases of Mexican trachoma, which was giving experimental promise in monkeys, and though a relatively sick man, Noguchi proceeded to Accra in November, 1927, to study the African yellow fever on the spot. It was in the midst of this investigation, which he was carrying out with his accustomed thoroughness and care, that he was stricken:

with the disease and died. Had he lived he would have been the first to announce the results of his labours and to acknowledge any errors of judgement he may have made. With his unrivalled technical ability he could not have failed to add to our knowledge of yellow fever, even if he had had to withdraw from the position taken up by him after his researches in South and Central America.

Though at the present time the yellow fever researches appear most prominent, and undue importance is liable to be attached to the presence or absence of a leptospira in the disease—a disease which has been practically wiped out from the New World as a result of data obtained before Noguchi even commenced its study—it must not be forgotten that in many other directions this indefatigable investigator made valuable additions to scientific knowledge. He studied the serological and cultural relationships of the various leishmania and allied insect flagellates, and was the first to differentiate these clearly by serological reactions. Working with Ohira, he even found time to attempt with success the culture of the oral *Trichomonas* of man. In 1923 he was investigating the serological and immunological reactions in Rocky Mountain spotted fever, and from the transmitting tick of this disease cultivated a rickettsia-like organism. In a series of more recent papers he described the cultivation of the virus of Oroya fever, and proved by monkey experiment that the causative organism, *Bartonella bacilliformis*, was common to this disease and verruga peruana, thus establishing, if the observations are confirmed, the identity of the two diseases—a fact which has been the subject of considerable controversy. He was also successful in transmitting the infection by means of the tick *Dermacentor andersoni*—an observation which may throw light on the etiology of the disease in South America. Noguchi's latest researches had to do with trachoma, and only a brief reference to them has yet appeared. In the midst of his work at the Rockefeller Institute—work in which his time was more than fully occupied—came the results of the Yellow Fever Commission in West Africa. All other work was put aside, and he set out upon what has proved to be his last journey of investigation.

Noguchi was a pioneer, and his output on original lines was enormous; and though, like his conclusions regarding the organism of yellow fever and those on rabies and poliomyelitis, some of his deductions may require qualification, his influence on scientific thought during the past quarter of a century has been all to the good, and has been the direct means of stimulating research in many directions. Had he lived there is no knowing what important additions he might have made to scientific knowledge. His death appears to be peculiarly tragic, for in what must have been a futile attempt to discover leptospira in West African yellow fever medical science has been deprived of a mind which was particularly adapted and equipped for dealing with many of the problems confronting it to-day.

A. C. E. HARRIS, M.B., F.R.C.S.,  
Birkenhead.

We regret to record the death, on May 18th, of Dr. Alfred Charles Edward Harris, at the age of 77. Dr. Harris received his medical education in Edinburgh, where he graduated M.B. in 1872 and obtained the L.R.C.S.; six years later he became F.R.C.S.

He went to Birkenhead some fifty years ago and soon built up one of the largest practices in the town. He held various appointments, including those of honorary consulting medical officer of the Wirral Children's Hospital, and honorary consulting physician to the Borough Hospital. He was for some time a member of the town council, and had been a magistrate since 1894. At one time he was president of the Royal Medical Society of Edinburgh and a staff surgeon of the old Royal Naval Volunteer Reserve. At the outbreak of war he rejoined his unit and assisted in the examination of recruits. He always took a very active interest in the work of the British Medical Association, and was a member of the Lancashire and Cheshire Branch Council from 1883 to 1900 and from 1911 to 1920; he was vice-president in 1893, and president in 1903. Dr. Harris

was also chairman of the Birkenhead Division in 1904, a representative in the Representative Body in 1913, and deputy representative from 1918 to 1920.

We are indebted to Sir JAMES BAUN for the following appreciation:

By the death of Dr. A. C. E. Harris of Birkenhead the medical profession has lost a worthy member and I have had covered a warm and unbroken friendship of over half a century. He was a man of sterling merits, incapable of any mean act, and was always highly respected and esteemed by his professional brethren. Dr. Harris retired from practice just before the war on account of failing health. When, in October, 1925, I had the pleasure of moving the congratulatory address to him on the attainment of his jubilee of membership of the Liverpool Medical Institution, his state of health did not permit him to be present, but the warmth of the reception of my motion was most enthusiastic, and he much appreciated the congratulations of his fellow members. He was always a keen controversialist, an able debater, and as an after-dinner speaker he had few rivals. He took considerable interest in local politics, and for some time was a member of the Birkenhead Corporation; at one time he was an ardent Liberal, but with him the welfare of the State was of more importance than that of party. As a Justice of the Peace he devoted much time to the work of the bench, especially after he retired from practice, and this work he continued almost to the end. He had very few hobbies outside his professional work, and unfortunately hard and persistent work was the main cause of his breakdown in health. He rarely committed his thoughts to writing, but he was an omnivorous reader of all classes of literature, had a well-stocked library, and kept himself well abreast of all advances in medicine. Of all the practitioners I have met in consultation he was the one I liked best. You could always feel that he had the confidence of his patients, and that the consultation was not forced on him, but that he was the primo mover, and in the selection of the consultant he had only the welfare of the patient at heart. Dr. Harris was very happily married, and during his long period of impaired health he owed much to the assiduous care of a devoted and beloved wife. He leaves a widow, a son, and three grandchildren to mourn their loss.

Dr. WILLIAM SNODGRASS, who died in Glasgow on April 23rd in his seventy-second year, was born of Scottish parents in the United States of America, but soon afterwards was brought to the Renfrewshire town of Paisley, where he received his early education at the John Neilson Institution; proceeding thence to the University of Glasgow. He graduated M.A. in 1878, and became a schoolmaster for a brief period. Subsequently he resumed his studies at the University and entered upon his medical career, graduating M.B., C.M., with honours, in 1886. In 1900 he was admitted to the Fellowship of the Royal Faculty of Physicians and Surgeons of Glasgow. After spending some time in physiological study at Berlin he was, in 1887, appointed Muirhead demonstrator in physiology at Glasgow University, and in this department he worked for ten years in close association with Professor McKendrick in a partnership which resulted in several important publications; and he was for some years an examiner in physiology for the Royal Faculty of Physicians and Surgeons. Histological preparations made a special appeal to his orderly mind, and his thoroughness as a teacher was widely appreciated. Dr. Snodgrass ultimately gave up this work to devote himself to his growing practice, which had developed rapidly. During his later years he took a prominent part in professional affairs. He was a member of the Royal Medico-Chirurgical Society of Glasgow and of the British Medical Association, in which he served as a member of Council for four years, from 1919 to 1922; he was also at one time an active member of the Scottish Committee of the Association, and had been chairman of the Glasgow North-Western Division. Among his colleagues he enjoyed an affectionate popularity, and his death has caused general regret. He is survived by his widow and two sons, one being a practitioner in Glasgow.

MR. WILLIAM JAMES FOSTER, F.R.C.S., who died suddenly at Boscombe, Hampshire, on May 11th, spent the greater part of his professional life at Reading, where he was in practice for over thirty years. He received his medical education at St. Mary's Hospital, London, and obtained the diplomas L.R.C.P. and M.R.C.S. in 1890, being admitted to the Fellowship of the latter body two years later. After service at St. Mary's Hospital as obstetrical officer, house-surgeon, and clinical ophthalmic assistant, he commenced practice in Reading in 1893. His association with the Royal Berkshire Hospital began six years later, when he was appointed assistant surgeon; he became full surgeon in 1914, and on his retirement in 1924 was appointed consulting surgeon. In the development of x-ray work in Reading Mr. Foster was a pioneer, and was mainly responsible for building up that department at the hospital. During the war he held a commission as captain in the R.A.M.C., and had charge of one of the main surgical blocks of Reading War Hospital. He was president of the Oxford and Reading Branch of the British Medical Association in 1922. He is survived by his widow and a married daughter; a younger daughter who entered her father's profession died while in resident charge of a hospital at Quetta. A colleague, "G. H. R. H.," writes: The friends of Mr. Foster in Reading were shocked at learning that he had passed away. He was an able surgeon, and up to the time of his retirement kept himself well abreast of the remarkable advances surgery had made during his professional life. He took a keen interest in the Royal Berkshire Hospital, both from the professional point of view and as a member of the board of management. His opinion as a radiologist was greatly appreciated by his colleagues, as, in addition to his report as an x-ray specialist, he was able to give an expert surgical opinion on the case under discussion. Foster was one of the straightest of men, and his death leaves among his friends a void which will never be filled.

## The Services.

### DEATHS IN THE SERVICES.

Major William Hunt, O.B.E., M.C., R.A.M.C., died in Queen Alexandra's Military Hospital, Millbank, on April 24th, aged 37. He was born on October 24th, 1890, and educated at Trinity College, Dublin, where he graduated as M.B. and Ch.B. in 1915. Immediately after qualifying he took a commission as lieutenant in the Special Reserve of the R.A.M.C., on October 6th, 1915. He took a permanent commission as lieutenant and temporary captain on June 1st, 1919, became captain on April 6th, 1919, and received a brevet majority on July 13th, 1922. Since February, 1919, he had been seconded for service with the Egyptian army, and, till he recently came to England, had been senior medical officer at Khartoum. He served throughout the last three years of the great war, was mentioned in dispatches in the *London Gazette* of December 21st, 1916, and December 24th, 1917, and received the Military Cross and the O.B.E.

Lieut.-Colonel Robert Drury, R.A.M.C.(ret.), died on January 23rd, aged 80. He was born on October 1st, 1847, and educated at Galway and in the Dublin School of the Royal College of Surgeons in Ireland, graduating as M.D. in the Royal University in 1870, and also taking the L.R.C.S.I. in 1871. Entering the army as assistant surgeon on September 30th, 1871, he became surgeon lieutenant-colonel after twenty years' service, and retired on May 3rd, 1902. He served in the South African campaigns of 1879-81, in the Zulu war, and in the operations against Sekukuni, receiving the medal with a clasp; also in the Transvaal campaign, or first Boer war.

Lieut.-Colonel Richard John Baker, Bombay Medical Service (ret.), died on January 13th, aged 69. He was born on December 29th, 1858, the son of John Baker, J.P., of Balrothery, county Dublin, and educated at Trinity College, Dublin, where he graduated as M.B. in 1880, having taken the L.R.C.S.I. in the previous year. Entering the I.M.S. as surgeon on April 2nd, 1881, he attained the rank of lieutenant-colonel after twenty years' service, and retired, with an "extra compensation pension," on August 12th, 1909. He served on the North-West Frontier of India in the Zhoib campaign of 1884—a small frontier "show" for which no medal was given. When the great war began in 1914 he rejoined for service, and was employed in the York Place Hospital at Brighton.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

### National Health Insurance Bill.

ON May 23rd the House of Commons considered the National Health Insurance Bill on report, and thereafter read it a third time without a division. Opening the report stage, Mr. CHAMBERLAIN moved an amendment authorizing the Minister to make provisional special orders excluding from the operations of the National Health Insurance Act particular persons. Sir KINGSLEY WOOD explained that clauses had been added to the bill to enable share fishermen to come under the National Health Insurance Act, and the proposed new clause would enable the Minister to exclude persons who were owners of fishing boats on their own account. Dr. VERNON DAVIES said the Minister was asking for a blank cheque. The new clause was added to the bill.

Mr. RHYNS DAVIES moved a new clause to permit an approved society with separate branches partially to pool its surpluses for mutual aid. Sir KINGSLEY WOOD said the clause should be rejected. National health insurance had never been so national as to-day, nor had so much money ever been distributed under it. Mr. KELLY said the proposal would allow the poorer branches to provide additional benefits. The proposed clause was rejected by 230 to 117.

After a further amendment dealing with share fishermen had been discussed and withdrawn, Dr. FREMANTLE moved an amendment to Clause 4, which deals with subscriptions by approved societies to charitable institutions. He proposed to add the words "or for the support of district nurses." These words had appeared in the 1924 Act, but had been omitted. If they were not inserted some approved societies might think they were no longer allowed to contribute to that purpose. Dr. DRUMMOND STIRLIS seconded, and the House agreed to the amendment.

Mr. RHYNS DAVIES moved to leave out Clause 13, which amends the sections of the principal National Health Insurance Act regarding the mercantile marine. Sir KINGSLEY WOOD explained that the clause provided for the schedule system in place of a stamped card system. There would be a voyage card giving short particulars of each seaman, but no stamps. Under the bill all seamen would be eligible for pension out of the Seamen's Pension Fund, as well as under the Contributory Pensions Act, at 65. The amendment was withdrawn.

On Clause 19 Sir KINGSLEY WOOD said Mr. Chamberlain and he would desire, if they could find a practical plan which would not unduly burden the national exchequer, to make the benefits of the national insurance scheme and of the contributory pensions scheme available to the small shopkeeper and people of that type. Under the clause people who for the first time would be covered for national health insurance purposes included hay-cutters working at picco rates; people working for timber merchants and forage merchants; stonebreakers and quarrymen; subcontractors in building and other trades; hedgers, ditchers, drainers, and thatchers; porters in wholesale fish, meat, and vegetable markets; slaughtermen and men of that kind.

Other administrative amendments were made, and Mr. CHAMBERLAIN then moved that the bill be read a third time. He said it endeavoured not to extend the scope of the national health insurance scheme, but, within its present financial limits, to improve the machinery and to give some relief where required. The bill offered generous treatment to persons who, by reason of genuine unemployment, had fallen into arrears with contributions. Discussion on the administration of additional benefits had resulted in agreement that there were some kinds of benefits, in the nature of medical benefits, which were not suitable for administration by insurance committees or even by approved societies. They had to contemplate in future, particularly in the administration of clinics, an arrangement under which there would be a joint representation of the professional men concerned in carrying out the service and of the approved societies. In the regulations to be made under the bill a more satisfactory administration of these benefits should be set up than in the past. A definite statement had been embodied in the bill of the right of the insured person to a free choice of dentist or doctor. A proviso specifically stated that regulations were not to restrict the right of any insured person to obtain treatment from any practitioner, clinic, or other institution with whom arrangements in respect of that form of treatment had been made in accordance with the regulations. He shared the regret that it had not been possible to include an arrangement whereby a specialist service could be provided for insured persons. That would be the greatest improvement which could be made at this stage to the general scheme of national health insurance. He hoped that in course of time this provision could be arranged, but approved societies generally had not accepted the recommendation of the Royal Commission that the specialist service should be obtained by pooling of surpluses. Therefore it was impossible to put that forward in the bill, but a little advance had been made towards it in the schedule of additional benefits. That dealt with payments to approved charitable institutions where insured persons might get the benefit of specialist treatment.

Mr. RHYNS DAVIES said every official of an approved society would be glad to see the bill become law.

Dr. VERNON DAVIES said the medical profession viewed the bill with some suspicion, and were not quite certain as to what might be its result. Owing to friction between the approved societies and the medical profession it was found necessary in the first National Health Insurance Bill to include statutory provisions concerning medical benefit. The medical profession retained that statutory right up to the present bill, but the Minister of Health had now withdrawn it and had given the profession the promise

of departmental regulations instead. The profession felt that a statutory provision was of much more value to it. The bill would enable a future Minister of Health to make regulations enabling the co-operative societies to start a clinic for eyes, ears, nose, or throat, and then to appoint their own doctors. The medical profession was anxious that the national health insurance scheme should be a success, and recognized that that could only be secured by co-operation between the approved societies, the profession, and the State.

Dr. DRUMMOND SHIELDS said the bill did not go far enough. If the Royal Commission suggested a method by which specialist services could be carried out, why did not the Minister of Health seek to carry it out? The Minister had been guilty of lack of courage in not tackling this question. So long as these services were not provided the national health insurance service gave the mass of the population an incomplete and inadequate medical service. In committee the medical members had tried to assure that the wives of approved persons should have, in confinement, adequate midwifery service. At present maternity money payment was, quite naturally, often used for other purposes, and confinements took place without medical or midwifery attendance. The Ministry of Health had in hand schemes dealing with this matter, which the medical members had not pressed on the report stage of the bill because they understood some effort was being made by the standing joint committee to achieve progress in this direction. The problem of maternal mortality was complicated and difficult, but everyone agreed that one thing to be done was to provide adequate midwifery attendance at the time of confinement. Dr. Shields commented on the fact that dental benefit was not provided until an insured person had been a member of an approved society for five years. By the school dental service a child could get dental treatment up to the age of 14, but then from 14 to 16 and up to 21 there were seven years without an effective dental service. Dental service should be given early. He had made representations to the Minister, and they were being favourably considered. Could the Minister say whether anything had been decided on which would make it possible for young people to obtain attention for their teeth immediately after they became insured persons? The bill showed a tendency to concentrate too much on the financial side of the scheme and on money benefits rather than on providing an efficient and comprehensive medical scheme for the insured person.

Dr. FREMANTLE said that medical members of Parliament looked at insurance bills not in relation to the pockets of the medical profession, but to the health of the community. In preventing disease and reducing sickness the bill of 1911 had not been so successful as was hoped. They had to remember that the insurance bill was watertight, so far as finance was concerned. What the House had to do was to rearrange the distribution of the fund. Members would find that the first seven of the new additional benefits were cash benefits. All through the cash benefit loomed larger than the benefits in kind. (Labour members: Why not?) The original insurance scheme was a balance between financial relief in time of distress and technical treatment for the cure, and still more for prevention, of the causes of that distress. They were glad the Minister had appointed a committee on maternal mortality, but statutory benefit for maternity, which was originally 30s. and no professional attendance, had been increased to an average of 46s. and still no treatment. It was not true that the people who received this money got the best treatment which could be provided. The Government in committee had opposed the proposal that additional medical benefit should be given in professional attendance by midwife or doctor. Those who looked after the health of the community hoped that they would get more of a professional and proper use of the funds of the insurance scheme. In that hope they welcomed the bill.

Mr. JOHN said the Association of which Dr. Fremantle was a member succeeded in removing from the original Act a clause which would have made possible a better system of maternity, specialist, and general medical treatment than was given in the bill. That clause enabled the workers of the country to form medical schemes and to co-ordinate different forms of medical treatment. Schemes in existence which would be wiped out under this bill—co-ordinated maternity, dental, surgical, and medical treatment. The Medical Aid Society had brought pressure to bear upon the Ministry of Health, and the possibility of co-ordinating these medical services was now being removed. The bill was then read a third time.

In a reply to Mr. Rhys Davies, on May 23rd, it was stated that in 1927 the amounts of the State grant on the non-cash benefits paid by approved societies in England and Wales were: dental, £438,300; ophthalmic, £53,510; hospitals, £56,760; convalescent home treatment, £15,950; surgical appliances, £9,520; convalescent or distress, £1,610; nursing, £730; providing convalescent homes, £720; repayment of contributions, £220. The total was £559,300, against £226,620 in 1926 and £169,020 in 1925. The State grant for dental benefit in 1925 was £97,150, and in 1926 £185,590; for ophthalmic benefit, £12,860 in 1925 and £25,250 in 1926, and for hospitals £48,760 in 1925 and £37,090 in 1926.

#### *Tuberculous Patients in Small-pox Hospitals.*

Mr. CHAMBERLAIN told Dr. Vernon Davies, on May 24th, that twenty-one small-pox hospitals had been used during the past three years for the treatment of tuberculosis, in one case for the summer months only. Tuberculous patients had been removed from these to provide accommodation for small-pox cases. At least three would not again be used for tuberculous patients, alternative accommodation having been provided or being in course of provision.

Dr. DAVIES asked whether Mr. Chamberlain knew that some of the tuberculous patients had to return to their own homes as no

savatorium accommodation could be provided for them. Mr. CHAMBERLAIN said some disadvantage attached to the use of small-pox hospitals for tuberculous patients, but when it was necessary for these hospitals to revert to their original use every effort was made to find other accommodation for the displaced patients. It was primarily for the local authorities to consider what steps should be taken to avoid some of these patients having to return to their own homes.

Dr. DAVIES asked whether Mr. Chamberlain thought that if the Vaccination Acts were more rigidly enforced he would be able to use some of this accommodation for cases of tuberculosis which were of a more serious nature than cases of small-pox at present.

Mr. CHAMBERLAIN said they could not entirely neglect the possibility of the occurrence of small-pox as to be able to dispense with small-pox hospitals.

*Education of Mentally Deficient and Delicate Children.*—On May 24th, answering Mr. Hollins, Mr. CHAMBERLAIN said that of the 125 local authorities under the Mental Deficiency Acts 21 had made direct provision of institutional accommodation for mentally deficient children. Others had provided for the accommodation of such children by contracting with the managers of privately owned institutions or with Poor Law authorities. All tuberculosis authorities included in their schemes provision for the institutional treatment of tuberculous children. Education was provided for tuberculous children who made more than a brief stay in a sanatorium, and education and training suited to their capacity was provided for all mentally deficient children while in an institution. Arrangements existed between the Ministry of Education, the Ministry of Health, and the Board of Control for co-ordinating the services in respect of mentally defective, delicate, and tuberculous children. Of local education authorities 2.5 per cent. provided nursery schools, 3.1 per cent. residential open-air schools, 12.9 per cent. day open-air schools, 2.2 per cent. residential schools for mentally defective children, and 23.6 per cent. day schools for mentally defective children. In addition, in areas such as London and Manchester classes attached to public elementary schools had been started more or less on open-air lines for young or delicate children.

*Stabilization of War Pensions Rates.*—Major TRYON (Minister of Pensions) announced in the House of Commons, on May 23rd, that, although existing rates of war pensions were safeguarded till 1931, the Government was considering the conditions under which stabilization of present rates of all pensions and allowances under Great War Warrants could be effected. Major Tryon hoped to be able to make a full statement before the end of the parliamentary session.

*Sheep Dip.*—Mr. GUINNESS, replying to a question on May 23rd, said that so far as he was aware there were no Home Office regulations regarding workers engaged in the manufacture of sheep dip or in dipping sheep. No Home Office regulations or instructions were given to persons purchasing sheep dip, the sale of which was governed by regulations made by the Privy Council under the Poisons and Pharmacy Acts. Mr. Guinness summarized these regulations, and added that the Ministry of Agriculture, under the Sheep Scab Order of 1928, required that all packages containing dips must be labelled with a label approved by the Ministry, stating the proportion in which the dip should be mixed and mentioning if it contained arsenic. The Ministry had widely distributed a leaflet advising persons how to use sheep dips.

#### *Notes in Brief.*

The Bethlehem Hospital Bill, which has passed the House of Lords, was formally read a second time on May 21st and sent to the Committee on Unopposed Bills.

The largest number of ex-service men, excluding those in mental hospitals, in receipt of hospital treatment at any one time during the first quarter of 1928 was 11,400.

On December 31st, 1927, in England and Wales, 14,260,000 persons were entitled to benefit under the National Insurance Acts. Of these, 9,210,000 men and 4,620,000 women were on the registers of approved societies.

Asked about the danger to the civilian population of an escape of phosgene or of other poisonous gases, Sir WILLIAM JOYNSON-HICKS announced that investigations were being made into the storage of gases under pressure.

Nine outbreaks of foot-and-mouth disease occurred during March; four during April, and eleven during the first three weeks of May. Of these, twenty were attributable to local infection from other outbreaks, and the source of the rest remains obscure.

## Universities and Colleges.

### UNIVERSITY OF OXFORD.

SIR E. FARQUHAR BUZZARD, K.C.V.O., M.D., Regius Professor of Medicine and Student of Christ Church, has been elected to an honorary Fellowship at Magdalen College, of which he was formerly a commoner.

### UNIVERSITY OF CAMBRIDGE.

Dr. ALFRED ERNEST BARCLAY, of Christ's College, has been appointed University Lecturer in Medical Radiology and Electrolology until October 31st, 1930.

At a congregation held on May 25th the following medical degrees were conferred:

M.D.—E. P. Hicks.  
M.B., B.Chir.—W. J. Moody, H. A. Clegg.

### UNIVERSITY OF LONDON. UNIVERSITY COLLEGE.

THE examination for the Bucknill Scholarship (160 guineas) and for two exhibitions (value 55 guineas each) will begin on June 26th. The subjects of the examination are chemistry, physics, botany, and zoology. The scholarship and the two exhibitions are tenable at University College, London. Entry forms may be obtained from the Secretary of University College, and must be in his hands not later than June 9th.

### UNIVERSITY OF LIVERPOOL.

THE Council of the University has received with regret the resignation by Professor J. W. W. Stevens of the Sir Alfred Jones Chair of Tropical Medicine, which he has held since 1913.

## Medical News.

SIR WILLIAM BEVERIDGE, K.C.B., Vice-Chancellor of the University of London, will distribute the prizes at St. Thomas's Hospital Medical School, in the Governors' Hall, on Wednesday, June 20th, at 2.30 o'clock. Academic dress will be worn, and there will be tea and music on the terrace.

SIR MAURICE CRAIG will take the chair at an "At home" in connexion with the Nurses' Missionary League on Thursday, June 7th, at 3.15 p.m., in the Church House, Great Smith Street, Westminster, when the Bishop of Blackburn will give an address. Invitation cards can be obtained from Miss Richardson, 135, Ebury Street, S.W.1.

THE Section of Urology of the Royal Society of Medicine will hold a special meeting on June 28th and 29th. On the afternoon of the first day there will be operations at St. Peter's Hospital, and at 8.30 p.m. Professor Juracz of Poznan will read a paper on movable kidney, to be followed by a discussion. On the second morning special instruments will be demonstrated, and at 2 o'clock there will be operations at St. Thomas's Hospital.

THE National Institute for the Deaf has arranged for a conference of delegates from universities, education authorities, special schools, and welfare societies for the deaf to be held at University College, London, on June 6th, at 2 p.m., with a view to placing the higher education and further technical training of the deaf and dumb on a more effective basis. We referred on September 18th, 1926 (p. 36), to the organization of the National Institute for the Deaf and the facilities then in existence for treatment. Further information may be obtained from the secretary of the Institute, 2, Bloomsbury Street, W.C.1.

THE annual pond life and general microscopical exhibition of the Royal Microscopical Society will be held in the lecture hall at 20, Hanover Square, W., on Wednesday, June 6th, from 7.30 to 10 p.m.

THE Committee of Inquiry on Lead Ethyl Petrol conferred, on May 25th, with Surgeon General Cumming, head of the Public Health Service of the United States of America. Dr. Leake, one of the senior officers of that service, was also present. The extensive researches which have been conducted in America by the Public Health Service and others for the purpose of ascertaining whether there was any risk of lead poisoning by the use of ethyl petrol were fully discussed. A further meeting will be held at the Office of Works, St. James's Park, S.W., on Wednesday next, June 6th, at 11 a.m., to take evidence from Sir William Pope, F.R.S., Professor H. B. Baker, D.Sc., F.R.S., and Professor G. I. Finch. The proceedings will be open to the public.

THE purpose of the eighth World's Dairy Congress, which is to be held in Great Britain this year, is "to effect an international exchange of the latest knowledge of the science and practice of dairying, and of the value of the use of milk and its products in the human dietary." The headquarters of the congress, which has been organized by a special committee in London acting in association with the International Dairy Federation, will be at the Central Hall, Westminster, from Tuesday, June 26th, to Saturday, June 30th, when the main work of the conference sections will be completed. On the following Monday and Tuesday sessions of the congress will be held at Reading, where the University is the seat of the National Institute for Research in Dairying, and the remainder of the week will be devoted to a tour in Scotland. On returning south special arrangements have been made for delegates to visit, on July 10th, 11th, and 12th, the Royal Agricultural Society's Show at Nottingham. Sir George Newman is president of the section concerned with milk consumption, administration, and control, which will meet on June 29th at the Central Hall, Westminster; among the papers are several of interest to those concerned with

dietetics or public health. A special section, meeting at Reading University on Monday, July 2nd, will deal with dairy bacteriological technique, the subject for discussion being the relative values of different methods of testing the cleanliness of milk. Membership of the congress is open to Government official delegates, representatives of local authorities and associations, and others interested. Particulars may be obtained from the organizing secretary, 28, Russell Square, W.C.1.

DR. D. S. DAVIES, who retired recently after forty-two years' service as medical officer of health for Bristol, was on May 24th presented with an oak bureau and bookcase from the members of the staff of the health department. The presentation was made by Dr. B. A. I. Peters, who expressed the hope that their former chief, now that he had retired, would be able to give the medical profession the benefit of his very extensive knowledge of epidemiology. In returning thanks Dr. Davies referred to the development in public health organization which had taken place in his service. At first the only hospitals belonging to the health authority were two wooden sheds close together in a stone yard, one labelled "fevers" and the other "small-pox." When they first built their isolation hospitals there was considerable difficulty in inducing parents to allow their children to go; they thought experiments were going to be made on the children. Tributes to Dr. Davies's work and to his personal qualities were paid by representatives of his former colleagues, lay and medical.

THE Chartered Society of Massage and Medical Gymnastics has published a register of members, covering the period from its incorporation by Royal Charter in 1920 to March this year, and containing the names and addresses of all massencers and massencers recognized as such by the society. Additional qualifications—for example, in medical gymnastics, in medical electricity, or as teachers—are noted, and the possession of other qualifications as nurses, midwives, dispensers, etc., is indicated. As a supplement to the alphabetical list there is a geographical list, giving the names of members under the postal district or place in which they reside. The register is published by the society at 157, Great Portland Street, W.1, price 4s.

THE report of the school of medicine of Shantung Christian University for the year ending June 30th, 1927, contains a short account of the progress of medical education until the end of March in that year, when it became necessary for all British and American subjects to leave. The school of medicine was closed by the authorities, but the hospital was carried on under Chinese management. Plans were well advanced for building a new hospital, but it is thought unlikely at present that the necessary money will be obtained. Emphasis is laid in the report on the importance of including more Chinese medical practitioners on the staff. The medical school was reopened in September, 1927, with twenty new admissions, as well as the majority of the old students, so that the work of training the Chinese in Western medical science is being continued.

A POST-GRADUATE course in malariaology will be held in Rome from July to September, which will include excursions to malarial districts. Further information may be obtained from the secretary of the Scuola, R. Clinica Medica, Policlinico Umberto I, Rome.

THE International Congress of Oto-rhino-laryngology will be held at Copenhagen, under the presidency of Professor Schnitzelgrew, from July 20th to August 1st, when the following questions will be discussed: radical, partial, or palliative operations in suppurative otitis media, introduced by Neumann of Vienna and Tapia of Madrid; septicaemias of pharyngeal origin, introduced by Forrer of Rome and Offenord of Marburg; diathermo-chirurgical treatment of malignant growth, introduced by G. Holmgren of Stockholm and Dan Mackenzie of London; anatomy of the ear and its influence on aural suppuration, introduced by J. Mouret of Montpellier, Portmann of Bordeaux, and Wittmack of Hamburg. Further information can be obtained from the general secretary, Dr. Mijeville, Place Vintimille 11, Paris, 9<sup>e</sup>.

DURING the first twelve weeks of 1928 more cases of meningococcus meningitis were reported in the United States than were recorded during the corresponding periods of 1926 and 1927, the figures being 1,179, 562, and 698 respectively. The highest prevalence is reported for the Mountain States and the lowest for the South Atlantic States.

As we go to press we learn with deep regret of the death from yellow fever of Dr. William Alexander Young, director of the Medical Research Institute of the Gold Coast, where Professor Noguchi was working at the time of his death. It is believed that Dr. Young contracted the disease in the course of a necropsy upon Professor Noguchi. We hope to publish an obituary notice in an early issue.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9561, 9562, 9563, and 9564** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:  
**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*  
**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*  
**MEDICAL SECRETARY**, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Racillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

### QUERIES AND ANSWERS.

#### MIGRAINE.

"M.R.C.S." who suffers severely from migraine, would be glad to hear from any fellow-sufferor whether luminal is of use as a prophylactic, and, if so, whether sodium bromide should be taken at the same time.

#### CIGARETTES AND SUCKLING.

"A. F. S." asks if excessive cigarette smoking on the part of a nursing mother would be injurious to a six-weeks-old infant and be likely to cause vomiting and general ill health.

#### ULTRA-VIOLET RAYS FOR ACNE.

Dr. T. M. GUTHRIE (Rock Ferry, Cheshire) asks what form of ultra-violet ray treatment is the best for chronic indurated acne of back and shoulders. Is a course of exposures at 36 in. for one and a half to two minutes to the rays of a mercury vapour lamp sufficient, or is something more stimulating needed, such as the Kromayer lamp actually pressed on the skin or held quite close?

#### ANGOSTURA BITTERS.

"T. D." asks: (1) What is the chemical nature of angostura bitters, and what, if any, are its active or toxic constituents? (2) What are its physiological or pathological effects? (3) Are there any known authentic cases of poisoning, chronic or acute, occurring as a direct result of the consumption of angostura bark?

\* \* \* The chief ingredient of angostura bitters is the angostura bark, also called cusparin bark. A good deal of work has been done on cusparin in times past, and numerous alkaloids have been found in it, but we are not aware of any evidence suggesting that the bark can be regarded as in any way toxic. It was formerly thought to have febrifuge and antiperiodic properties, but its virtues are, in all probability, merely those of an aromatic bitter tonic. We have been unable to find any record of a case of poisoning, acute or chronic, as the result of consuming the bark in any form. Two recipes for angostura bitters are given in *Pharmaceutical Formulas*, issued from the office of the *Chemist and Druggist*. Each contains angostura bark and alcohol as the principal ingredients, with cardamom seeds, cinnamon, and orange peel as flavourings. The second formula includes also cinchona bark and gentian root.

#### INCOME TAX.

##### Renewal of Car.

"A. C. R." sold his car in July, 1927, and is being allowed £640 as obsolescence, that amount wipes out his Schedule D income, if not his entire taxable income, and therefore he receives no benefit from the children's and life assurance allowances. Can he spread the deduction over, say, the next two years?

\* \* \* No; the amount must be treated as an expense of the year in which the replacement was effected. "A. C. R." can, however, carry forward the loss resulting from so treating the expense and deduct that amount from the income of 1928, and

can also claim to have the personal and similar allowances for 1928-29 granted from his other income—by repayment, if necessary.

#### Claim to Three Years' Average.

"J. M." commenced practice on September 30th, 1924, having terminated his assistantship two months earlier. He was assessed for 1925-26 on the amount of his earnings for that year—presumably as having commenced a new practice. Can he claim to be assessed on the basis of the three years' average for 1927-28?

\* \* \* The average can be claimed under certain conditions by "any person who for the year 1926-27 was assessed and charged under Schedule D . . . upon an average of a period of three years or more. . . ." (Finance Act, 1926, Section 29 (3).) If, as we understand, "J. M." was regarded for income tax purposes as having started a new practice, he will have been charged to tax for 1926-27 on the basis of his first year's earnings and not on "an average . . . of three years." In such circumstances he is not within the relieving section quoted above.

### LETTERS, NOTES, ETC.

#### BRONCHO-PNEUMONIA IN CHILDREN TREATED BY INJECTIONS OF EMETINE.

Dr. T. DOUGLAS ROSS (Glasgow) writes: In your issue of May 19th (p. 844) Dr. C. Robertson Wilson recorded the results of treatment of fifty cases of broncho-pneumonia with injections of emetine hydrochloride. He notes that, while in some cases the febrile period seemed to be shortened by emetine, in others the drug had no apparent effect. I suggest that his successful cases (apart from some that might have done well with no medicine) were examples of the homeopathic action of emetine, and that the cases which did not respond needed some other drug, according to their particular symptoms. Fifty children with broncho-pneumonia differ widely one from the other. One may show anxiety, restlessness, an after-midnight aggravation of symptoms, and excessive prostration—indicating arsenic. In another, intense thirst for big cold drinks would suggest phosphorus; if with this thirst there is profuse head sweat, verruca viridis is indicated. In my experience ipecacuanha is needed fairly frequently, especially at the commencement of pneumonia in children, when nausea and vomiting are prominent, the respirations are rattling from excess of mucus, and the cough is spasmodic, almost suffocative. When this rattling is present in cases nearly moribund, and the child seems almost suffocated with its bronchial secretions, tartar emetic is preferable, and often saves a life.

#### WHOLESALE EXTRACTION OF TEETH.

Dr. R. N. BURTON (Invercargill, North Queensland) writes: Is it not time that a halt was called in regard to the indiscriminate extraction of teeth on insufficient grounds? On a number of occasions I have seen patients urged to have all their teeth removed, the only local indications being a slight retraction of the gums or a slight gingivitis. A brief discussion with any patient who has had all his or her teeth extracted would, I am sure, convince any medical man that there are grave mechanical and other disadvantages attached to the wearing of dentures. I am convinced that in many cases where the trouble is attributed to a patient's teeth this is a refuge and not a diagnosis. I would suggest that before advising the serious step of wholesale extraction a doctor should satisfy himself that the teeth in question are definitely loose, or that apical sepsis is clearly demonstrated by x rays. If there is any doubt as to the cause of the malady (and I submit that in many cases where the patient's teeth are blamed there is grave doubt), instead of ordering a wholesale extraction of teeth the patient should be given the benefit of that doubt and treated on general lines, and instructed to return in, say, six months' time for another examination.

#### INTRAVENOUS TREATMENT OF VARICOSE ULCERS.

At the combined meeting of the Sections of Dermatology and Surgery of the Royal Society of Medicine on May 16th, reported in our last issue at p. 897, the chair was taken not by Mr. Davies-Colley, but by Dr. J. M. H. MacLeod, President of the Section of Dermatology.

#### HARVEY TERCENTENARY BANQUET.

PHOTOGRAPHIA, LTD. (17, Cheshamside, E.C.2), ask us to say that their flashlight photograph of the Harvey tercentenary banquet in the Guildhall may be obtained in three sections, No. 1 being the centre section, No. 2 that on the president's left, and No. 3 that on his right.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 48, 49, 50, and 51 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 235.

## An Address ON MATERNAL MORTALITY FROM PUERPERAL SEPSIS.\*

AN ANALYSIS OF THE FACTORS OF CONTAGION, TRAUMA,  
AND AUTO-INFECTION.

BY

JAMES YOUNG, D.S.O., M.D., F.R.C.S.,

PHYSICIAN, EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL  
HOSPITAL; ASSISTANT GYNAECOLOGIST, ROYAL INFIRMARY,  
EDINBURGH.

It is unnecessary in these days to emphasize the tragic importance to the community of the large mortality amongst young women which is incurred yearly through child-bearing and childbirth. In these islands the maternal death rate is about 4,000 each year; between 1911 and 1926 inclusive there were 66,421 deaths from these causes in England and Wales. Septic infection is by far the most important single cause. According to the official figures for 1926 the total maternal mortality for England and Wales was 5.14, and the sepsis mortality 1.60, per 1,000 live births.

This loss by death, however, is in some ways not the gravest consequence of child-bearing, for we have come to realize that, for each mother so lost, there are many more whose health is in varying degrees chronically undermined by the damage they have sustained in childbirth. Infection and mechanical damage thus acquired are amongst the main causes of the frequent chronic ill health which dates from childbirth. We can assess within accurate limits the loss by death, but of the incidence of persisting invalidism of child-bearing origin we have no exact knowledge. We know with certainty, however, that many of the common gynaecological disorders, the uterine haemorrhages, the leucorrhoeas, the pelvic pains, the displacements, etc., and many general disturbances, debility, indigestion, neurasthenia, rheumatism, etc., are to be traced to the lesions of childbirth. It is probably not an over-statement to say that about 60 per cent. of hospital gynaecology is a legacy from vitiated child-bearing, and of this a very large part falls into the category of infection.

Septic inflammation of the genital canal during labour or in the puerperium may, as a useful basis for analysis, be considered as falling into one or other of three clinical types according as it is caused by (1) contagion, (2) trauma, or (3) auto-infection.

In the case of *contagion* we are dealing with an invasion of the passages by a virulent septic micro-organism, which is introduced from without. Here, as in other infective diseases—for example, scarlet fever, erysipelas, typhoid, or tetanus—our etiological quest is dominated by the consideration of the nature, virulence, and source of the infecting microbe. This type of puerperal infection is seen in its simplest form when it occurs after a normal, easy labour, with an absence of trauma of the maternal passages, and in this category are to be classed the epidemic scourges of the maternity hospitals of a former day.

Puerperal sepsis due to *trauma* is, in its essential etiological features, entirely different from that caused by contagion. Here the factor which dominates the issue is a lacerating or contusing damage of the walls of the birth passages, and the source and nature of the infective organisms become a matter of comparatively secondary importance. By this is meant that it is the trauma of the soft parts that determines the risk of sepsis. The infecting microbes which can determine the infection in such a case are notoriously widespread in nature. They may be considered as being derived exogenously or endogenously; in either case they may conceivably consist of micro-organisms which only cause disease when settling in devitalized tissue. The point of clinical importance, however, is that these somewhat theoretical matters concerning the origin of the microbe are overshadowed by the vital issue of trauma.

The third clinical type of puerperal fever is that caused by *auto-infection*. Here the micro-organisms which set up

the pelvic inflammation are, in some cases, present in the genital canal before labour begins—for example, in an infected cervix. In other cases they reach the genital passages from some distant source by direct spread or by implantation—for example, from the bowel—or they may travel by the blood stream from areas of focal infection in teeth, tonsils, etc. Auto-infection, like contagion, operates in its simplest form when it supervenes in a normal spontaneous birth in which there has been a minimum of interference and trauma.

The essential distinction between these three clinical types of puerperal infection is in no way undermined by the consideration that, in some cases, two of the factors concerned may be operating together. Where, for example, trauma has occurred the fact of contagion or of auto-infection may constitute an important contributory agency. Before we can hope to grapple with the menace of puerperal fever a knowledge of the manner and degree in which these three factors operate is necessary. Until we have this knowledge much of our effort must be largely haphazard. My purpose in this paper is to draw attention to some considerations which, although they claim no finality, point to possible avenues of approach to this intricate problem.

### AUTO-INFECTION.

The importance attaching to this mode of infection becomes apparent when we note that within recent years many observers have attempted by its means to explain infection occurring in those spontaneous cases which have not been examined at any stage of labour. Further, it is clear that, if operating in an appreciable ratio, it would go far to explain the persisting high death rate from sepsis despite the application of the aseptic principle; Victor Bonney and others have urged its importance with considerable force and plausibility, and its possible significance is referred to in the recently published report of the Committee appointed by the British Medical Association (*Supplement to the British Medical Journal*, April 28th, 1928, Appendix iv, p. 165). Undoubted examples of auto-genous infection can be cited—for instance, puerperal fever arising during scarlet fever, erysipelas, etc.

A consideration of the available data, however, suggests that as a factor in the death rate autogenous invasion probably plays a minor part. In a subsequent part of this paper I shall refer to some facts which emerge from a study of the practice of the maternity hospitals during the pre-Listerian days, and shall adduce evidence that in these old lying-in institutions puerperal fever was a negligible cause of death during those periods when contagion was obviously in abeyance. Equally suggestive evidence may be found in an analysis of the records of many extensive maternity practices at the present day. The extern practice of the Edinburgh Maternity Hospital shows a consecutive series of about 5,000 spontaneous births with 2 deaths from sepsis; the extern department of the Birmingham General Hospital records 888 cases with an absence of sepsis mortality; whilst there is the record of 47,503 deliveries, both normal and abnormal, in the unselected practice of the East End Maternity Hospital in London with 5 deaths from sepsis, or 1 in 9,500. The practice of the Queen Victoria's Jubilee Institute midwives is likewise instructive. During 1927 there were 53,502 deliveries with 6 deaths from sepsis in normal spontaneous births, or 1 in 8,900 of the total. If we include all the deaths in this record of 53,502 cases which can directly or indirectly be attributed to sepsis, and including normal and abnormal cases, we get a maximum figure less than 0.5 per 1,000. To the production of this figure all causes have contributed.

The fact which seems to emerge clearly from these data is that the very small sepsis rate in these large and unselected bodies of women is an argument against self-infection operating alone being an appreciable component of the sepsis death rate in the rest of the community. It is especially important that our ideas on this question be clarified, because much of the uncertainty and confusion in the minds of those who are anxiously seeking a remedy for the present state of affairs springs from the difficulty in assessing the true significance of this factor.

Much recent bacteriological research has been directed to the elucidation of these questions, more especially in an

\* Communicated to the Edinburgh Obstetrical Society, May 9th, 1928.

attempt to relate the vaginal and cervical flora with the incidence of puerperal sepsis. As a result of this work we must now concede a comparatively frequent occurrence of streptococci in the genital passages of pregnant women, but, although it is established that puerperal infection is commonly caused by strains of streptococci, there is no evidence that the streptococci frequently present in the genital canal can play any part in initiating this infection. The fact of their frequent presence, combined with the rarity of puerperal sepsis in the absence of other factors which have a determining role, such as trauma, implies that this streptococcal flora possesses practically negligible primary virulent properties. Another finding which bears directly on this question is that, although severe puerperal infection is usually caused by a haemolytic streptococcus, the type present so frequently in the genital canal is of the non-haemolytic variety (Bigger and FitzGibbon,<sup>1</sup> Lockhart,<sup>2</sup> Colebrook<sup>3</sup>). Recently Burt-White and Armstrong<sup>4</sup> record the finding of streptococci of various kinds in the cervix of 40 per cent. of 55 pregnant women examined. In one only did the strain present the characters of *Streptococcus pyogenes*, the common cause of puerperal fever. In 15 of these cases, including the one harbouring *S. pyogenes*, the women were followed through their puerperium, and in none did symptoms arise.

We thus see that the consensus of bacteriological study is against the view that the bacteria of the genital canal play any primary part in puerperal sepsis. These observations are entirely in keeping with, and at the same time corroborate, the clinical observation of large series of deliveries to which I have directed attention. Whilst along such lines the inference would seem to be well established, we must, however, not entirely shut our minds to the possibility that the normally innocuous denizens of the genital canal may, under certain conditions, assume pathogenic properties—for example, after trauma and devitalization of tissue.

The data, when so marshalled, would seem to warrant as a reasonably safe conclusion the view that auto-infection as a primary factor plays a quite unimportant part in the death rate from sepsis, and that in our search for essential causes we must address ourselves to the remaining factors of contagion and trauma.

#### CONTAGION.

Contagion is known to play a part in puerperal sepsis at the present day, as witness pelvic infection following contact with the virus of scarlet fever, or the epidemic deaths which occasionally occur in maternity homes and hospitals. To study the features of this type of infection satisfactorily, however, we have to turn to the records of the pre-Listerian lying-in hospitals. Epidemic waves of the disease were, as is well known, the scourge of these institutions. For example, "in the large hospital at Vienna, out of 21,120 women delivered from 1840 to 1846, 2,260 died; or about 1 in every 10 mothers delivered perished, chiefly from puerperal fever."<sup>5</sup> In 1774 at the Hôtel-Dieu, Paris, every patient attacked died—altogether about half the patients confined in the hospital.<sup>6</sup>

The striking lesson for us is that, in these old hospitals, puerperal fever would seem to have been so predominantly a matter of contagion that other factors were largely negligible. I have been strongly impressed with this somewhat remarkable fact during a recent study of the records of the old Edinburgh Maternity Hospital. From 1823 to 1844, out of 3,906 women delivered in this hospital, 75 died from all causes. The records are not complete enough for an accurate differential analysis of the causes of death for this whole period, but in one of his striking papers on puerperal fever Sir James Young Simpson<sup>7</sup> gives accurate data for the period from 1823 to 1837, when there were 47 deaths among 2,890 women delivered; 36 out of these 47 deaths were, according to Simpson, due to puerperal fever. When we turn to the records we find that the distribution of these deaths is instructive. We discover that 50 occurred in three years, when obviously contagion was rife. On the other hand, during the four years 1826 to 1829 inclusive there were 821 successive births without a death. We may deduce from this that during this period

of fifteen years, when contagion was eliminated, there was little or no mortality from puerperal fever.

The records of other hospitals exhibit the same facts. Thus Collins, the master of the Dublin Lying-in Hospital, reported a series of 16,654 births during the seven years dating from November, 1826, with 88 deaths from puerperal fever, all occurring during the first three years. He says that "for the four remaining years of my mastership we did not lose a single patient from this disease,"<sup>8</sup> which implies 8,000 or more successive cases without a death from puerperal fever.

In retrospect it cannot but impress us as remarkable that, despite the dangers lurking within the walls of these older hospitals, and the consequent wholesale sacrifice of women during the eighteenth and nineteenth centuries, no widespread attempt to disestablish the system is apparent. Every now and then, it is true, a warning voice is raised in reputable medical circles.\* Furthermore, we know that the women midwives engaged in a bitter contest with the men midwives on this and other questions.

The fact that contagion was the dominating cause of puerperal fever in those days is brought out also by a study of the records of the outdoor practice of the hospitals. In this connexion the records of the Edinburgh Maternity Hospital from 1826 onwards, which I have recently had an opportunity of studying, are instructive. At that period the indoor department was limited to destitute cases, and the arrangement by which abnormal cases were removed to hospital did not come into operation till well beyond the time which these records cover. The outdoor practice may, therefore, be taken as representing the average type of midwifery of the class of women concerned. This was carried out by the students attached for service to the hospital and by the midwives, who, as we know, at this period had little or no scientific training.

Between 1826 and 1857 there were 15,144 successive deliveries with 61 deaths—that is, a rate of 4 in 1,000. The cause of death is given in 44, and in 19 it is stated as puerperal fever—that is, about 43 per cent. If we assume that this figure applies throughout the series the sepsis deaths would represent under 2 per 1,000 deliveries. I have shown that, in the indoor department, there were considerable periods without any mortality from sepsis, clearly due to the chance absence of contagion. The same is true of the outdoor practice. Thus there is a record of 3,288 successive births during the nine years from 1839 to 1847 with no sepsis deaths. The elimination of this element brings the total death rate during this period down to 5 in 3,288, or about 1.5 per 1,000.

The figures I have just quoted, embracing as they do a fairly extensive record of what may be taken as the average midwifery in Scotland about a hundred years ago, naturally challenge comparison with the practice of the art at the present time. Before any legitimate comparison is possible, however, it must be recognized that the above figures refer to deliveries and abortions, and do not include deaths from such complications of pregnancy as hyperemesis and ectopic gestation, which appear in the ordinary maternal mortality returns of the present day, and which constitute about 10 per cent. of the deaths in the Registrar-General's Report for Scotland. The births in Edinburgh during the years 1924 to 1926 numbered 24,173, and the maternal death rate was 5.6 per 1,000. By deducting 10 per cent. we get an amended rate of 5.1 per 1,000, as against the comparable rate of 4 per 1,000 in the case of 15,144 deliveries in the outdoor practice of the Edinburgh Maternity Hospital about a century ago.

The limited figures just quoted support the belief that during the past hundred years there has been no depreciation in maternal mortality, and this is in accord with the national statistics. For Scotland the decennial mean figures from 1855 to 1914 are 4.9, 5.1, 5.2, 5.3, 4.6, and 5.6 per

\* Thus, in discussing the second annual report of the Edinburgh Maternity Hospital, December 18th, 1845, a contributor to the *Monthly Journal of Medical Science* (vol. vi, 1846, p. 269) points out that the death rate in the hospital was 1 in 25 women delivered, whereas the death rate in the outdoor practice of the hospital was 1 in 331. He then remarks that "the question, therefore, naturally arises whether it would not be better to improve the comforts of the poor women at home during their confinement, rather than advise them to enter the hospital. . . . At best, they are of questionable propriety, as they are so apt to become foci of deadly disease."

1,000 births, and the mean for the period 1915 to 1922 is 6.2. Likewise the proportion of deaths from sepsis during this period has shown little change—namely, 1.7, 1.8, 2.0, 2.5, 1.9, 1.7, 1.7.

To realize the significance of these findings we must visualize the manner in which childbirth was managed in the pre-Listerian days and how this differed from our modern methods. The first fact of which we must remind ourselves is that our predecessors had no knowledge of aseptic or antiseptic procedure. It is abundantly clear that it is to this we must attribute in the main the ravages of puerperal contagion, for they examined freely during labour, and, in cases of retained placenta, they had no hesitation in introducing the hand into the uterus. Abdominal expression of the placenta by the Credé method did not, in point of fact, come into use till about 1867. The other important fact regarding the practice of those days is that it was based firmly upon the teaching of Harvey, Smellie, Hunter, Denman, and others, who insisted that child-bearing was a physiological process, which must be left to Nature, and which was apt to be vitiated by interference on the part of the accoucheur. This was to be stringently withheld until Nature's effort had unmistakably failed. Instruments of any sort were the last refuge. Simpson, for example, in the Edinburgh Maternity Hospital, used the forceps in 1 in 472 labours, and other hospitals had a similar record. In studying these old records and noting what to us seems almost the extremity of patience with which the tedious cases were managed, one is tempted to wonder how far the factor of exhaustion and delay may have contributed to the frequency of infection. This, however, does not seem to have been a factor of any moment, for Collins, in discussing this very point, reports that in 71 out of his 88 deaths from puerperal fever the labour was completed within twelve hours.

These old records have a further bearing on the subject-matter of our discussion, for, as we know, there was little regard paid to the danger of repeated vaginal examination. Despite this, and the obvious and common contamination of the genital passages which must have then occurred, there was a negligible mortality from sepsis except where virulent contagion was present. This suggests that the microbes introduced by such contamination had little infectiveness in the case of labour conducted with a maximum regard to physiological needs.

The records of these pre-Listerian times would seem to suggest that, although contagion was a common cause of death, trauma was a factor which operated comparatively rarely, and this we must attribute to the principles which then underlay the practice of the art. I have shown that so strongly was this the case that at times the results obtained by our forefathers were such as compare favourably with the best practice of the present day.

It would clearly be to our advantage could we analyse the factors that stand behind the present high rate of sepsis as satisfactorily as is possible in these older records. Unfortunately in modern times the subject is hedged around with difficulties and uncertainties that make the study baffling in its complexity.

#### *Contagion as a Factor in the Present Sepsis Death Rate.*

How far contagion or trauma, or both combined, are responsible for the death rate from sepsis at the present time we have no accurate means of discovering. If we address ourselves first to contagion we have, however, certain data which are worthy of analysis. In this connexion we have to remember that virulent contagion notoriously may act where there is a minimum of interference, and the invasion of the genital canal may even occur when there has been no vaginal examination at all, the microbes being then conveyed to the vaginal opening on the fingers or dressings of the medical attendant or nurse, or in some other way. In pre-Listerian practice the high death rate was dependent upon such infection of the normal case, and the extent and severity of the danger were reflected accurately in the ratio of such cases involved. In any large practice the criterion of the normal case provides a sufficient index of the degree in which this factor is operating. It is clear that the omission of the abnormal and instrumental case from such an analysis does not vitiate the

result *qua* simple contagion. If the sepsis rate in such cases be increased because of the major interference employed it is legitimate to attribute such increased risk to the interference and the possible trauma incurred.

We have, at the outset, to remark that the massive sepsis of the pre-Listerian days, when surgical contagion repeatedly overwhelmed the surgical and maternity wards and often spread into extra-hospital practice, is no longer with us, and it would seem certain that the elimination of this virulent and spreading contagion must necessarily have led to a lessening of this contact factor in modern practice. Despite this, however, we know that contagion does still operate—as, for example, where the scarlatinal virus is transmitted to a parturient woman, or where two or more women are clearly infected from one common source. The exact extent to which infection so conveyed is responsible for modern sepsis is, however, more difficult to define than in the case of the older records. Whilst this is so, we are not altogether without evidence. The figures I have already quoted in connexion with auto-infection are again of service here. In the outdoor practice of the Edinburgh Maternity Hospital, for example, during four years there have been about 5,000 normal deliveries with 2 deaths. During the year 1927 there were 53,502 deliveries in the practice of the midwives of the Queen Victoria's Jubilee Institute in England and Wales with 6 deaths from sepsis in normal births—that is, 1 in 8,900 total deliveries, or about 0.1 in 1,000. This total figure refers, of course, to all cases, normal and abnormal. If we exclude the forceps cases we get a figure approximately equal to 1 in 8,000 or 0.12 in 1,000. This indicates the rarity of contagion in the practice of midwives, and when we remember that in England and Wales over 50 per cent., and in Scotland over 30 per cent. of the maternity service of the community is in their hands, we have ample reason for the belief that, in this proportion of the country's service at least, contagion is of comparatively minor importance. Then we have a record of 47,503 successive cases in the outdoor and indoor practice of the East End Maternity Hospital, with a total of 5 deaths from sepsis, or 1 in 9,500 cases. It is, of course, not necessary to conclude that all the sepsis deaths in these records are due to contagion. The figures are quoted with the object of indicating the maximum possible mortality from this cause when this is operating alone.

I have given these data not because they demonstrate necessarily any superiority in the practice of the institutions concerned over that obtaining throughout the rest of the community in respect of this matter of contagion, but for the reason that they constitute the only large series of figures available. It is not easy to conceive any reason why this small ratio of contagion should be appreciably different in the rest of the community not covered by these precise records. In other words, such an analysis as I have given leaves in one's mind the impression that contact infection, while it does admittedly still occasionally operate to maintain the incidence of fatal puerperal sepsis, is probably a factor of comparatively minor value, and that to explain the persistently high rate in modern practice we have to direct our attention to other factors.

#### *Contagion in Present-day Hospitals.*

To the enduring benefit of labouring women we have to acknowledge with ungrudging gratitude that the era inaugurated by Lister has brought assurance into obstetric practice, and in no way is this more strikingly manifest than in the enhanced safety of the modern maternity hospital and in the surgical procedures on behalf of the mother and child on which we now embark with confidence. At the same time the magnificence of this great new instrument is apt to blind us to the fact that even in the hospital system of our own times there are still perpetuated in some degree the risks with which our forefathers battled in vain. There is still intrinsic in it the danger incidental to the assembling of numbers of parturient women within four walls. The reality of this risk is at once apparent when we recall that, whilst the main practice of such hospitals is concerned with normal childbirth, it is also largely engaged in serving, and in attracting to itself, often from a wide district, the abnormal, which is often synonymous with the

frankly or potentially infected case. This is especially true of the large central hospitals, where the fact of numbers naturally multiplies the risks. A study of this problem has long convinced me that these risks are by no means negligible, for, even when the technique of the hospital is good, the risk of the leakage from infected to clean case can never be completely blocked, more especially at times when the hospital practice is working at high pressure.

In support of these contentions I may quote the figures of one well-known hospital, for which I am indebted to the registrar. During four years, in 4,278 normal spontaneous deliveries there were 72 cases of puerperal fever with 5 deaths. In yet another well-known hospital during one year there were reported 11 instances of puerperal infection in spontaneous births with 3 deaths in cases in which the birth is described as quite normal. The report of another large hospital shows that, out of 27 deaths from puerperal infection in one year, there were 4 deaths in women in whom the birth was spontaneous and uncomplicated. These hospitals are all actively engaged in abnormal midwifery in addition to catering predominantly for the normal birth, and there can, I think, be no doubt that in the majority of the instances cited the infection is transmitted by contagion from abnormal to normal case. But the added risk to the normal by no means exhausts the dangers of a hospital, for it is obvious that the difficult and abnormal case which has suffered trauma is itself especially liable to succumb to contagion. Similar instances of hospital contagion are related in the Royal Society of Medicine Report on Puerperal Sepsis<sup>6</sup> and in Dame Janet Campbell's *Protection of Motherhood* (1927, p. 18).

The problem is thus seen to be a complicated one, and, although I do not on this occasion intend to enter into a full discussion of the means required to block this risk of leakage, I would remark that an imperative need of every hospital and home is a complete separation at every stage of the normal and the suspect case. The admission, the examining, the labour rooms, and the wards of the two sets of cases must be rigidly isolated from one another, and the same rigid separation must apply to the nursing. The risk of patient-to-patient transmission is further lessened by the adoption of the small ward principle, especially for the abnormal delivery. In many instances we know that maternity hospital buildings are inadequate, and, in their present state, are unable to meet the demands which a rigid application of the modern ritual of prevention implies.

I feel that, although the consideration of such questions introduces matters of some delicacy, it is urgent that they be reviewed in the frankest possible manner at this time, because, as we all know, there is a strong advocacy in some quarters of an increase in maternity hospital accommodation as one means towards remedying puerperal mortality and morbidity (Janet Campbell, Munro Kerr, Johnstone, and others). Whilst finding myself in sympathy with this attitude, I must admit that I consider any such widespread experiment as having elements of danger, except it be carried out with the most stringent regard to the safeguards I have mentioned. The exact proportion of the total sepsis death rate which this hospital contagion implies we have no means of determining. That, however, we may safely consider it as comparatively small is indicated by the meagre share of the total births which occur in hospital. The maternity hospital beds officially known by the Ministry of Health to exist in England and Wales number only 2,280 in 149 institutions (Janet Campbell, *Protection of Motherhood*, 1927, p. 64).

#### TRAUMA.

I have already stated that the factors behind the persisting sepsis rate are complex. One example of this suggests itself to the mind. It is often urged that we have lost to parturient women the advantages of a century's progress because we have vitiated child-bearing by a too great recourse to instrumental delivery. It is true that interference with the natural process, by instrumental or other means, was in the old days employed at the most in only one out of several hundred cases, and that, even under the best conditions nowadays, such physiological child-bearing is only rarely found. Even in the case of the practice of the Queen Victoria's Jubilee midwives, who, it may be argued, deal with the most normal class of case, the forceps

deliveries number about 6 per cent. of the total, and in the East End Maternity Hospital, where physiological child-birth is rigidly aimed at, the instrumental rate is over 2 per cent. Over the rest of the community we may safely conclude this rate is still higher.

Faced by this indisputable evidence it is not surprising that many have urged that trauma is at the back of modern sepsis. It cannot be denied that there are cases—and every member of the staff of a maternity hospital can quote instances—in which unjustified interference has led to disaster. On the other hand, to argue on the basis of such individual cases—which usually spring from lack of experience and well-intentioned though over-anxious zeal—that trauma inflicted by malpraxis is the essential cause of the persisting death rate is to lose sight of other factors which may have a wide-reaching significance.

One of these factors concerns the possible change in the fitness of women for child-bearing and childbirth as compared with their sisters a century ago. During this period there have been gross changes in the mode of life and feeding of the community. Moreover, we have to consider the possible and special bearing of rickets. It is not improbable that the increased protection of child life, which constitutes one of the most remarkable features of modern social hygiene, may have increased the proportion of those with skeletal defect who survive into adult life. As an obstetrician practising amongst the same class of women as those with whom Sir James Young Simpson had to deal nearly a century ago, I am convinced that the need for intervention on mechanical grounds is now greater than it was then, when forceps were employed only in 1 in every 472 cases.

Whilst it is thus undoubtedly arguable that traumatization has played in recent times an increasingly important part in puerperal sepsis—and the data analysed earlier in this paper would seem by a process of exclusion to lead the evidence incriminatingly in this direction—it is at the same time not improbable that at the back of it there are some structural factors not wholly within our control, and therefore not wholly preventable by us as obstetricians. Whilst making these somewhat sombre admissions we have at the same time good cause for hope, for, as I have exemplified by the instances I have quoted, there are many indications pointing towards a better and possible provision for the parturient woman if we are prepared to take advantage of them. The practical conclusion to which my studies have led me is that, whilst auto-infection can be largely displaced from the platform to which it has been raised by some, and whilst contagion likewise probably plays only a secondary part, to trauma from interference it would seem we have to ascribe the chief agency in the maintenance of sepsis, although we are not warranted in assuming that the main burden of responsibility is to be placed on the medical attendant.

The fact that, with a well-organized maternity service, a greatly diminished mortality rate is obtainable points clearly the way to progress, and suggests that the immediate problem for the community is the provision of better machinery for bringing to the help of labouring women the knowledge we possess, rather than the pursuit of a mark-time policy which awaits the outcome of further research.

In support of this contention I would instance the experience of the Queen Victoria's Jubilee Institute, which last year had the splendid record of 53,000 deliveries with a mortality of .72, or 1.3 per 1,000. It is to be noted that these figures refer to the combined practice of midwife and doctor, for medical practitioners were called in to the aid of the midwife in 25 per cent. of the cases. It is a very successful and encouraging example of team work. The midwife's task is only made possible when it is united to the knowledge that she has the doctor behind her in case of need, whilst, on the other hand, the fact that the routine management of the practice is in the hands of the midwife makes for the possibility of a more physiological attendance of the normal case than is to be expected from the practitioner, with whom midwifery is often a disturbing item in the course of a busy day interspersed with urgent calls, and from whom, moreover, regardless of every other consideration, there is too often demanded a speedy termination of labour. It may be argued that the small death rate

in this large practice is dependent upon the fact that the midwives' cases are to some extent selected. This is not denied, and that this selection is not inconsiderable is suggested by the very low death rate in the series from puerperal convulsions and albuminuria—from 0.1 to 0.2 per 1,000, as contrasted with a death rate over the rest of the community of from 0.6 to 0.8 per 1,000. Making every allowance, however, for these facts the record is full of encouragement, and points to the advantages to be obtained from a wider extension of the midwife-doctor system.

The signal advantages of such combination are even more convincingly demonstrated by such an institution as the East End Maternity Hospital in London, where the bulk of the cases are conducted by midwives, and abnormal cases are treated by medical practitioners on the honorary staff. This institution conducts over 2,000 cases yearly; about half being in the hospital. There is a well-organized ante-natal system, and the forceps rate is under 3 per cent. Despite the fact that the practice is amongst the very poor, and that it is practically unselected, it has a mortality rate standing at a little over 1 per 1,000 cases. For four years, in a total of about 9,000 cases, it sank to the extremely low level of 0.67 per 1,000. Sepsis is practically eliminated from this practice, and there can be little doubt that this is due mainly to the excellent administration, the careful supervision, and the low instrumental rate.

It is to be specially observed that the admirable results obtained in the case of these extensive practices flow entirely from the method and machinery employed. There is installed by comparatively simple means a system by which—and this is especially noteworthy in such an institution as the East End Maternity Hospital—the physiological management of labour is encouraged, the abnormal case is seen betimes, and difficulty and danger are thereby anticipated and prevented. The record of this institution and its almost complete freedom from sepsis is one of the most cogent arguments in support of the contention that the dominating factor behind sepsis in ordinary midwifery is trauma. So remarkably successful has this hospital been in its effort to expel from its doors not only sepsis, but also the other complications of labour and the puerperium—for example, eclampsia—that we might at first sight feel ourselves compelled to attribute the result to some unduly favourable circumstance in the material of their practice. Against this, however, it may be urged that the official records show that the death rates of the communities in which this hospital carries on its work are several times greater than that exhibited by the indoor and outdoor practice of this institution.

It cannot, I believe, be denied that the evidence furnished by an enlightened and critical analysis of all the various forms of maternity effort we have reviewed goes to support the contention of Fairbairn and others that "a country's maternity service is best built on the foundation of a service of midwives with medical help in difficult cases." Before this ideal can be universally realized much must be done in the way of education of the public and in the reorganization of the present machinery of practice. Doctors can do a great deal in both directions; and there is ample evidence to hand that in these objects they can count on the help of the central and local authorities. The problem in any area can only be satisfactorily dealt with by strenuous local effort.

The high death rate in some areas invites the suggestion that on occasion the subject may become eminently a matter for the active interest and participation of the local body.

#### CONCLUSIONS.

1. Autogenous infection is a minor primary cause of fatal puerperal sepsis.
2. Contagion is probably of comparatively secondary importance. The well-established risks of contact infection in hospitals call for care in the extension of the hospital system of maternity service.
3. There is evidence that trauma is the most important cause of the death rate from sepsis. This is not entirely a problem involving the medical attendant; it has implications of a wider nature.
4. The immediate need is an improved machinery for maternity practice based on a midwife-doctor combination.

From the standpoint of immediate policy the importance of this overshadow all other considerations—for example, "research"—and there is reason for the hope that by this means alone a lessening of the death rate is possible.

5. Improved education of the public, the midwife, and the student, and the assistance of the central and local authority, are all necessary for the creation and working of a satisfactory machine.

## A Lecture

ON

## PUERPERAL SEPSIS.

DELIVERED TO THE BLACKBURN DIVISION OF THE BRITISH MEDICAL ASSOCIATION

BY

A. REMINGTON HOBBS, M.D.,

MEDICAL SUPERINTENDENT, ST. MARY ABBOTS HOSPITAL; CONSULTING GYNAECOLOGIST TO THE ROYAL BOROUGH OF KENSINGTON.

In considering the present state of affairs relating to puerperal sepsis, it would seem that during the last twenty years no progress has been made, in spite of our knowledge of antiseptics and of bacteriological research. In support of this statement I may mention that—

1. No fewer than 3,000 British mothers die every year in childbirth.
2. Of a number of patients examined at a certain welfare centre, 50 were still bleeding at the end of several weeks, of whom 20 came from one hospital.
3. At a similar centre 42 cases returned septic, of whom 28 had been treated by general practitioners and 6 at maternity hospitals.
4. Dr. Harold Miller's investigations at Pittsburg show that of 1,000 women examined as soon as possible after the sixth week following labour no fewer than 70 per cent. showed some degree of erosion of the cervix.
5. Of the fatal cases, 80 per cent. afford a history of operative or manipulative intervention.
6. Inflammation dating from some previous confinement or miscarriage is present in 70 to 80 per cent. of gynaecological cases.

What do we understand by the expression "puerperal sepsis"? In this connexion we may consider the definition of puerperal sepsis enunciated by the Ministry of Health and based on the suggestions of the Royal Society of Medicine—namely, that puerperal sepsis is (a) a fever; (b) a bacterial infection of the raw surfaces left after labour.

Is it a fever? It is true that some cases of puerperal sepsis may be attended by pyrexia, but this is the exception rather than the rule. In support of this it may be submitted that (1) all practitioners meet with many instances of yellow vaginal discharge unassociated with pyrexia; (2) in a large percentage of cases of secondary haemorrhage a high temperature never develops; (3) a patient may die from secondary haemorrhage or gangrene of the uterus without any pyrexia; (4) of 340 patients delivered in a maternity ward in 1926, 83 suffered from uterine sepsis—one-half of these septic cases exhibited pyrexia and the other half secondary haemorrhage.

Is it a bacterial infection of raw surfaces? If so, the inflammatory changes occurring as the result of retention of placental tissues or blood-clot and lack of free drainage are lost sight of, and the significance of these changes in the etiology of uterine disease fails to be recognized.

Immediately after labour or miscarriage a cascade of blood and serum exudes from the raw surfaces for a period

of some days' duration. If there be any interference with the outflow of this fluid symptoms and signs entirely due to pent-up secretions will manifest themselves.

I may summarize the main sites of obstruction as follows:

1. *In the Uterus.*—The two main sites in the uterus are the wall and the cervical canal. As regards the uterine wall, the flow of lymph may be impeded by inflammatory products, by injury caused by the finger or curette, by the use of strong styptics, or by too hot douching. Similar obstruction in the cervical canal may be caused by retained blood-clot, pieces of membrane, placental fragments, or the swollen and congested cervical mucous membrane.

2. *Outside the Uterus.*—Interference with the outflow may be caused by a loaded rectum, an overdistended bladder, oedema of the vaginal walls subsequent to pelvic cellulitis, and by swelling and oedema of the perineum.

A loaded rectum plays an important part in damming back the uterine secretions, the symptoms being due, not to absorption from the bowel, but to pressure from the loaded bowel preventing the secretions from being discharged. The following reasons may be adduced. (1) An overloaded bowel must distend anteriorly and not posteriorly. (2) On examination, the finger passes over a distinct hillock and the cervix is above and behind the lump. (3) In 200 cases the height of the uterus was measured before and after an enema. It was observed that the uterus descended on each occasion after the bowel was evacuated. (4) In 1918 the records of 100 patients examined in the maternity wards showed pyrexia in 18 per cent. of cases between the second and fifth days. In 1926 this percentage was only 5 following regular washing out of the bowels for the first three days. (5) In the case of one patient in the maternity ward who had temperature and pain the loaded rectum was emptied and 5 c.cm. of pus was drawn off from the uterus; an uneventful recovery followed.

#### **PATHOLOGY OF PUERPERAL SEPSIS.**

We now turn to the question of the pathology of uterine sepsis. It is probable that if every student studied microscopical sections taken from cases of this disease he would arrive definitely at the decision that the uterus must be drained. The following is a summary of what is found.

1. *Normal Endometrium.*—In a normal case the surface is covered by a continuous line of columnar cells. The gland acini are similarly lined, are fairly uniform in size, and are more or less circular when seen in cross section. The gland lumina are empty and their mouths opening into the uterine cavity are patent. The stroma is composed of slightly elongated connective tissue cells with intercellular fibrils. The stroma cells are loosely packed together, not widely separated as in an oedematous uterine wall. The blood vessels are small and few. There is no evidence of haemorrhage or necrosis.

2. *Acute Endometritis.*—Here the surface is devoid of covering columnar epithelium. In its place are masses of fibrin and exudate together with large decidual cells, some still living, others necrotic. There are small collections of extravasated blood and numerous polymorph leucocytes. The glandular elements are absent. In other words, the mucosa has become necrotic and has largely disappeared. Hence we find, immediately under this layer of necrotic debris and decidual cells, the somewhat oedematous fibromuscular wall of the uterus. There is great dilatation of blood vessels, which appear much more numerous than usual, and some of these vessels contain polymorph leucocytes and are thrombosed. There are numerous collections of polymorph leucocytes studded about in the muscle; some of these foci are virtually small incipient abscesses. Finally, the muscle fibres are swollen and somewhat more separated than usual.

3. *Chronic Endometritis.*—In this condition the covering of columnar epithelium is practically normal. The gland acini are all more or less dilated and larger than normal, but they are irregular in their shape. The mouths of those which are visible open on the surface, are somewhat narrowed, and the lumen in many instances is no longer empty, but contains inspissated secretion, occasional frag-

ments of shed epithelium, occasional leucocytes, and occasional erythrocytes; these contents connote chronic inflammation. The stroma cells are much more widely separated than normal by oedema. There is a slight capillary enlargement and also small stromal haemorrhages. Lastly, there is a general sprinkling of leucocytes, chiefly mononuclear, but occasionally polymorphonuclear.

#### **TREATMENT.**

In the first place let us consider the nature of some of our present methods of treatment and the reasons for their failure.

1. *Expectant or Conservative Treatment.*—This method has frequently caused bitter disappointment. It leaves too great a task to Nature, because in more than half these cases there is evidence of pent-up uterine secretion. It fails to keep the cervical canal clear. In the canal may be seen pieces of blood-clot, placenta, or membrane, which give rise to the symptoms and signs of obstruction. No one can say that the best method of treating secondary haemorrhage is to leave the uterus alone. Even with the aid of drugs such as pituitrin and ergot, and of the well-known douche tin, the patient is frequently no better off. It is often followed by intermittent pyrexia, and it leaves the uterus with no standard of cure.

2. *Curetting.*—I cannot do better than quote the words of Sir Bernard Spilsbury: "In all bad cases of uterine infection there is presumptive evidence of the introduction of some material, surgical or other, into the uterus." There are too many instances of a flare up where this surgical method has been employed. Cases have been numerous in the past where this method failed to stop secondary haemorrhage.

3. *Dilatation and Swabbing with Strong Styptics.*—This method often fails because there is a likelihood of severe reaction following the application of strong corrosives.

4. *Douching.*—It has been demonstrated that douching does not relieve the uterus of its pent-up secretions. This was illustrated some years ago by the case of a woman whose uterus was drained and subsequently douched; the temperature rose, but she was later cured by treatment with glycerin.

5. *Hot Intrauterine Douche.*—This method is often followed by symptoms and signs of septic absorption. It injures the tissues and prevents drainage.

6. *Scrums and Vaccines.*—These seem to have no effect if the tissues of the uterus are not drained.

It therefore appears to be established that, judging from the number of curettings performed, our treatment in the past has left us without a proper standard of cure. What, then, is the ideal method of treatment? Is there a method that can be applied again and again without being followed by an exacerbation of the fever or disease; each application fulfilling the purpose of an aid to the drainage of tissues in a state of stasis—a method that alleviates pain, relieves congestion, and by so doing stops secondary haemorrhage, and finally restores the functions of the uterus? I am certain that there is, and that method is the mode of treatment by glycerin which I have described.

In considering the indications for treatment it is necessary to think of the ante-natal clinic, the labour room, and the lying-in ward.

1. *The Ante-natal Clinic.*—It is important to see that all methods of investigation and treatment are carried out. The necessity of accurately measuring the pelvis is generally recognized, but there is also the question whether any toxins are present, as evidenced by albuminuria. I wish particularly to emphasize the importance of the presence in certain cases of bacteria in the urinary and genital tracts; this also applies to septic conditions. If bacteria are present, treatment should be employed to eliminate them, or, at any rate, to diminish their number. If these conditions are not fulfilled, pathological organisms may show their presence during labour without any vaginal examination having been made.

2. *The Labour Room.*—With regard to infection during labour, there is a type of case in which labour starts with

a rise of temperature, often to a considerable height, and with perhaps a rigor, and in which an accompanying urinary infection may lead to failure to recognize a uterine infection. Here the false belief may arise that, because organisms and cells have been found in the urine, the diagnosis is complete. If there has been any internal manipulation we prevent sepsis by administering an intra-uterine injection of 120 c.cm. of glycerin as a prophylactic. In the case of retention of the placenta, if ordinary methods have failed we inject 60 to 100 c.cm. of glycerin into the uterus. In many cases this has aided expulsion of the placenta without recourse to manipulation. In the presence of excessive haemorrhage manual removal must, of course, be performed at once. As regards post-partum haemorrhage, we employ the same treatment, injecting 60 to 100 c.cm. of glycerin into the uterus, and have found this method most successful. If the haemorrhage shows no sign of ceasing under the treatment it is advisable to explore the uterus for retained products.

3. *The Lying-in Ward.*—In connexion with sepsis a much higher standard must be arrived at, and the fact must be realized that not every case of sepsis gives rise to pyrexia. If, however, the patient shows, for example, a temperature of 99° F. and a pulse rate of 80, the uterus should at once receive treatment. It is unwise to look for some septic focus other than the uterus, and, having established a diagnosis of influenza, pneumonia, bacilluria, mastitis, mumps, or femoral thrombosis, to treat the case as such, forgetting the uterus. It seems extraordinary that in just the few days of the early puerperium all these diseases should attack the woman, and that they should ignore her during the remaining three hundred and sixty. A few illustrations may be advisable.

(a) *Influenza and Pneumonia.*—I need not dwell on the fact that two of the gravest complications that we have to contend with during the puerperium are influenza and pneumonia. We know the severity of the symptoms and that patients often die within a few days. The reason for this seems to be that the patient has a double infection. It is difficult sometimes to decide which is the primary infection or whether a general infection is present, but we are convinced of the existence of the latter when the lochial discharge is prolonged and profuse; we know then that the patient has a poor chance of recovery. We have seen several cases in which the patient has died during the early puerperium, and on section the uterus has shown acute inflammatory changes.

(b) *Phthisis.*—Quite recently I was asked to see a case of phthisis. During pregnancy the patient had had no temperature, but on the second day of the puerperium it rose. The doctor who examined her thought that her symptoms were due to her chest. She had three attacks of shivering during the first week, and on examination the lochia were found to contain *B. coli* and streptococci. The urine was sterile.

(c) *Mumps.*—I have found that when the parotid gland becomes swollen and tender during the puerperium the uterus generally escapes attention. On January 2nd a patient was sent into hospital on the tenth day after delivery with swelling and tenderness of the right parotid gland. Three days later this was followed by enlargement and tenderness of the right breast. The uterus showed signs of sepsis.

(d) *Femoral Thrombosis.*—In this class of case we are convinced that the uterus is septic and should be treated accordingly.

(e) *B. coli Infection.*—A short time ago I was asked by a gynaecologist attending a case of bacilluria complicating the puerperium why the temperature failed to drop. I told him that Dr. Donaldson had examined the urine in 100 cases of pregnancy and had found *B. coli* in 25 instances, in all of which there was infection of the lower genital tract. I suggested that he should wash out the uterus with glycerin. This was done, with the result that the temperature shortly afterwards subsided. In all these cases our experience tends to show the existence of a double infection.

(f) *Mastitis.*—In cases of pronounced mastitis it is in our experience customary to find an underlying uterine infection, and it is advisable to treat the uterus.

#### SIGNIFICANCE OF PAIN AND TENDERNESS IN UTERINE SEPSIS.

In a normal puerperium, whether in a primipara or a multipara, there should not be irregular contractions of the uterus. Some years ago I was impressed by the case of a multipara who was stated to have had irregular pains during the second night following delivery. The vagina was thoroughly swabbed and the uterus syringed out with glycerin, thereby getting rid of a considerable amount of blood-clot. The pain disappeared immediately after treatment. The only conclusion to be derived from this case was that pain is the cardinal symptom and tenderness the cardinal sign of an obstructed viscus; in other words, the condition was uterine colic and obstruction. The cause of the obstruction was obviously the blood-clot; moreover, pathologists state that the contact of blood-clot with raw surfaces for some hours produces inflammatory changes in a brief period. This and other cases definitely prove that after-pains are pathological and not physiological.

Pain and tenderness are not by any means confined to the maternity wards, but they tax all the ingenuity of the surgeon in the gynaecological department; numerous cases reach hospital labelled "pelvic peritonitis," "abdominal influenza," and "appendicitis." Given a case of well-marked peritonitis of the lower abdomen it is, in the experience of every surgeon, difficult to diagnose whether the appendix or the tubes are at fault, and on occasion one is certainly justified in opening the abdomen. But the point I wish to emphasize is whether we have brought every method of investigation and diagnosis into play, because in many instances, after opening the abdomen, surgeons find not appendicitis, but an acute inflammatory condition of the uterus, tubes, and pelvic peritoneum. These cases should be approached in a careful and methodical manner. The history is of importance, since the origin of the trouble may date from some inflammation in the uterus left after labour, abortion, or gonorrhoeal infection. The points in the history are:

1. If at any previous labour or miscarriage the lochia has persisted beyond the seventh day suspect uterine sepsis. This sign may have been present years before, and it connotes infection from an infected surface.
2. Intermittent temperatures preceding or accompanying menstruation indicate an endometrium infected by organisms, and a condition of stasis.
3. Dysmenorrhoea, whether appearing for the first time or becoming progressively acute with each menstrual flow, indicates sepsis.
4. Backache, discharge, erosion, and metrorrhagia following labour or miscarriage indicate sepsis.
5. A visual examination of the cervix and a bimanual examination should be made.

#### Typical Cases.

1. A woman came into hospital some weeks after a miscarriage with prolonged red lochia. She had been in the ward three days with a temperature of 99° F. when one evening she was suddenly seized with acute abdominal pain and vomiting; the temperature was 103° F. and the pulse 120. The lower abdomen was acutely tender, and there was rigidity. On bimanual examination the uterus was found to be enlarged, boggy, and tender, with impaired mobility and fullness in the lateral fornices, especially on the right side. The mucous membrane of the cervical canal was swollen and oedematous, and contained thick mucus. There was obviously an acutely spreading peritonitis, and pain and tenderness of the uterus—the symptoms and signs of an acutely inflamed viscus. It might be said that there were two wells of water being slowly filled, one in the uterus and one in the pelvic peritoneum. It is usual in these cases to watch the abdomen for the overfilling of the second well, and then to operate; but it occurred to me that if I drew the water from the first well—in other words, pent-up secretion from the uterus—the second well (the peritoneum) might be able to deal with itself. I therefore gently washed out the cavity of the uterus slowly drop by drop, using only about 1 c.cm. of glycerin. I put the patient back to bed and sat her up in the semi-Fowler position. In two hours I found that the temperature had fallen to 99° F. and the pulse to 90. The acute abdominal pain had gone, but there was a feeling of soreness. The diagnosis could only be acute uterine colic and obstruction with adnexal inflammation. The patient slept for five hours and made an uninterrupted recovery without the abdomen having been opened.

2. Another patient was sent in some months after confinement as a case of appendicitis with a history of sudden pain in the right iliac fossa and vomiting. The temperature was 101° F. and the pulse 112. Abdominal examination revealed pain and tenderness low down in the right iliac fossa. Bimanual examination

showed an enlarged, tender, and boggy uterus with distinct tenderness in the right lateral fornix. A little glycerin was injected into the uterus, and four hours later the temperature and pulse rate fell and the patient was free from pain.

Another factor of importance is the abnormal prolongation or excessive degree of the red lochia, which is a significant sign, liable to menace health or even to cause death. If the uterine products are expelled after the third stage of labour, provided there is no sepsis, the red lochia should change from the fourth to the sixth day. Again, if the uterus is empty and is washed out with glycerin for the first few days, the lochia soon cease.

I was much impressed by a case of pneumonia complicating labour which was sent into hospital. The patient was delivered and died on the fifth day afterwards. As the lochia were excessive sections of the uterus were cut, and it was found to be full of small abscesses and most congested; in other words, the patient died not only of pneumonia, but also of secondary haemorrhage. It is evident, therefore, that if pneumonia and influenza complicate the puerperium there is usually a general infection. These events can explain at any rate one of the causes of the high mortality in epidemics such as influenza.

The importance of secondary haemorrhage is indicated by the following cases.

A patient had been ill for eight weeks after her confinement, the temperature ranging between 100° and 101° F. and the pulse between 110 and 120; she had a double femoral thrombosis. The doctor who had been called in said that the uterus was normal; but the second consultant informed me that the patient had had two haemorrhages since her confinement. The surgeon took this to be evidence of secondary haemorrhage, and the uterus was immediately treated with glycerin, with the result that the temperature quickly fell.

Another patient bled for six weeks after her confinement; this sign is evidence of sepsis. She was curetted, but the bleeding still persisted. A year afterwards she was curetted again, with the same result. She received x-ray treatment three times a week for three months, but the haemorrhage continued. She was then given a general anaesthetic and the uterus was washed out with sp. vini methyl. and glycerin. She received half-hourly treatments morning and evening, and the haemorrhage stopped in five days. Daily treatments were continued for another ten days, and then she had her first normal period for two years. She has now quite recovered.

As the result of these investigations I am convinced that there is a dividing line where the red blood from a healthy wound ceases and the haemorrhage from an inflamed surface begins. It is difficult to be sure when secondary haemorrhage commences, but usually it is in the neighbourhood of the fifth to the seventh day. If women are not to be allowed to fall into a state of chronic invalidism the inflammatory surface must be treated with a drug like glycerin, which relieves the inflammation producing the haemorrhage.

Septic miscarriage is comparable with puerperal sepsis, differing only in that the former is more liable to be due to retained products of conception. No attempt is made to remove any retained products, except when pieces present at the os, or there is severe haemorrhage. By far the worst cases admitted to St. Mary Abbots Hospital have been those where attempts have been made to remove retained products either by the finger or the curette. The cause of the rise of temperature is retained septic secretions and not necessarily the products themselves. This fact has often been demonstrated by draining the uterus, when the temperature falls before the expulsion of the contents.

The following statistics illustrate the work carried out at St. Mary Abbots Hospital.

Total number of patients delivered since 1921 ...	1,657
Cases exhibiting temperature 99° F. and over ...	134
Cases of secondary haemorrhage (past two years ... 644 cases) ...	102
Number of deaths from puerperal sepsis ...	Nil
Number of anaesthetics administered after third stage of labour ...	2
(a) Dry labour—general peritonitis—laparotomy within 40 hours of delivery—recovery.	
(b) Secondary haemorrhage following manual removal of placenta—curetted for retained piece—nil found—report of curettings: acute endometritis.	
Number of abortions and miscarriages (2 years) ...	192
Cases with retained products (2 years) ...	104
Cases with curettings (2 years) ...	10
Number of explorations (2 years) ...	10

## CONCLUSIONS.

We have arrived at the following conclusions as the result of the research work carried out at St. Mary Abbots Hospital during the past few years.

1. The definition of puerperal sepsis laid down by the Ministry of Health is inadequate and erroneous.

2. As regards the first part of the definition, puerperal sepsis is not by any means invariably accompanied by a rise of temperature. Pyrexia is merely a sign in the course of a septic process, and this is one of the main reasons why a large number of cases of puerperal sepsis are allowed to pass unrecognized through our best maternity hospitals.

3. The second part of the definition requires amending also. Inflammation can be caused by agents other than bacteria. Retained blood-clot and fragments of membrane or placenta will act as foreign bodies and will lead to inflammatory changes in the uterus.

4. Pain and tenderness must be recognized as the commencement of uterine colic and obstruction. Pain and tenderness are never physiological, but are invariably pathological after the third stage. Moreover, so long as the symptoms and signs of acute uterine colic and obstruction are not added to the list of abdominal inflammations, and are not treated as soon as these signs appear, so long will patients be subjected to abdominal explorations, whereas they might have been saved.

5. It will soon be no longer the fashion for women to bleed for weeks, months, or even years after their confinements, because students will be taught that glycerin will relieve the inflammation which produces the haemorrhage.

6. The uterus never was, and never will be, cleaned in one attempt.

7. After curetting and swabbing with strong styptics the uterus must be drained for the succeeding few days.

8. The best time for treatment is in the early days of the puerperium.

9. Every septic case following labour or miscarriage should be investigated by the health visitor and reported to the medical officer of health.

10. A special ward should be attached to every maternity hospital so that every septic case could be transferred and treated, and, if necessary, treated after leaving the hospital, since many women take their discharge on the fourteenth day and before they are cured.

11. A doctor who is skilled in the detection of the early symptoms and signs of puerperal sepsis and the modern treatment thereof must in future be attached to every large maternity hospital.

## PUERPERAL SEPSIS AND SENSITIVENESS TO STREPTOCOCCAL TOXINS.

BY

H. BURT-WHITE, M.D. LOND., F.R.C.S. ENG.,  
SURGEON TO OUT-PATIENTS, HOSPITAL FOR WOMEN, SOHO SQUARE;  
ASSISTANT OBSTETRIC SURGEON, CITY OF LONDON MATERNITY  
HOSPITAL.

THE anomalous distribution of puerperal sepsis has long puzzled epidemiologists. It is stated that women in good surroundings have suffered more frequently from this disease than the poor, and that rural districts show a higher incidence than towns. The number of cases in hospitals and nursing homes is likewise in excess of those occurring among women delivered in their own homes. True a greater number of abnormal cases, requiring manipulation, are to be found in institutions, and similarly the incidence of septic cases among primiparae has been considered due to the difficulties which necessarily attend a first labour.

It is especially significant that great advances in obstetric technique have done little to lessen the incidence of puerperal sepsis. That puerperal sepsis is caused by the *Streptococcus pyogenes* is now generally accepted, but a source of virulent *S. pyogenes* must be present before the disease may develop. Where is it to be sought?

As already shown in a recent paper by R. R. Armstrong and myself,<sup>1</sup> streptococci are not by any means invariably

inhabitants of the cervical canal during pregnancy. The true virulent disease-producing *S. pyogenes* occurs very rarely in the female passages, in all probability only when a woman has been recently associated with a source of infection. It seems that infection is not necessarily by actual contact, although the exact means of transference is at present obscure. Proof of this is furnished by the clinical histories of local and institutional epidemics of puerperal sepsis. Again, our experiments prove that a woman does not necessarily succumb to puerperal sepsis, even though she be actually harbouring the infection.

Neither first pregnancy, difficult labour, nor aggregation of cases in institutions in which the relative density of *S. pyogenes* infection is inevitably high, will account fully for the capricious incidence of puerperal sepsis. Our general knowledge of infection and response suggests that in this, as in other diseases, individual reaction and personal immunity against the infecting micro-organism are important safeguards. This view receives support from the work of Okell and Parish, who believe that all the disease-producing strains of *S. pyogenes* are identical, in the sense that their main aggressive weapon is a toxin, which is the same for all strains.<sup>2</sup> Hence an attack, during her girlhood, of streptococcal sore throat, of cellulitis, erysipelas, or even scarlet fever, may be expected to have conferred on a woman a greater or less degree of protection against the most virulent and fatal form of streptococcal infection, puerperal septicaemia. It is a recognized fact also that a woman who has once suffered from puerperal sepsis is seldom or never attacked in subsequent pregnancies.

Attempts in the laboratory, with experimental animals, to demonstrate and measure antistreptococcal immunity have proved quite unexpectedly unsuccessful. Yet the value of some foreknowledge of the reaction of a primipara to *S. pyogenes*, with the implied possibilities of prophylactic immunization before delivery, is beyond dispute.

The investigation to be described was initiated to test the reaction of pregnant women to the scarlatinal toxin, without any preconception as to results. An experiment at St. Bartholomew's Hospital by Sir Frederick Andrewes<sup>3</sup> on a number of hospital students showed that a proportion were sensitive to scarlatinal and other streptococcal toxins. This experiment did not altogether make clear the correlation of toxin-sensitiveness with a past history of scarlet fever or streptococcal infections. With the accumulation of data the test on women has come to assume positive significance, as each has been followed through her pregnancy, labour, and puerperium.

A supply of standardized scarlatinal toxin, prepared at the Wellcome Research Institute, was kindly furnished by Dr. C. C. Okell, whose pioneer work on the toxins of the *Streptococcus pyogenes* group is generally recognized and acclaimed. The preparation has been used in all tests. Four intradermal injections, respectively one-fifth of a cubic centimetre of a dilution of 1 in 1,000, 1 in 3,000, and 1 in 6,000 of toxin with control, were made into the skin of the palmar surface of the forearm. A positive reaction consists in the appearance within twenty-four hours of an erythematous patch, varying somewhat in size with the intensity of the reaction and the dilution employed, from one-quarter of an inch in diameter to an area one inch or more in length. In about half the cases gradation in response is apparent, corresponding with the strength of toxin employed. But in many cases there is little to choose between the high and low dilutions. In general practice it will probably be found sufficient to employ only a dilution of 1 in 1,000 to discriminate between reactors and non-reactors.

The tests were made on women at St. Bartholomew's Hospital and the City of London Maternity Hospital. One hundred cases have been tested, and their labours and puerperia observed. Of these 100 women, 27 were toxin-sensitive, while 73 did not react to any dilution. The cases may be grouped as follows.

#### (a) Women Giving Positive Reactions.

Of 27 women, 8 experienced morbid puerperia, according to the British Medical Association standard. In only 2 cases were the cervixes swabbed, but each yielded a pure

growth of *S. pyogenes*. The high percentage (30 per cent.) of morbidity is remarkable when it is considered that 6 of the 8 women passed through normal labours without any interference, while the other two sustained only slight post-partum haemorrhages. The details of each case may be summarized.

1. Normal labour; morbid puerperium.
2. Normal labour; post-partum haemorrhage; temperature 100° F.; second to eighth days, maximum temperature 102° F.
3. Normal labour; morbid puerperium; temperature 100.2° F., fourth and fifth days.
4. Normal labour; morbid puerperium; *S. pyogenes* isolated from cervix.
5. Normal labour; morbid puerperium; post-partum haemorrhage; *S. pyogenes* isolated from cervix.
6. Normal labour; morbid puerperium.
7. Normal labour; morbid puerperium.
8. Normal labour; morbid puerperium.

The remaining 19 women passed through normal puerperia; 18 of these experienced normal labours, one was delivered by forceps.

#### (b) Women who did not React.

In this group there were 73 women. Two of these experienced morbid puerperia, but in each case the constitutional disturbance was very slight, and in neither could *S. pyogenes* be found in the cervix or blood. The series was of special interest in that it contained many abnormal cases in which sepsis was to be expected, yet, as will be seen from the summary below, no such event occurred.

1. Severe post-partum haemorrhage; admitted pulseless. Manual removal of placenta performed after blood transfusion. Normal puerperium.
2. Patient delivered on district; severe post-partum haemorrhage, associated with a morbidly adherent placenta which required manual removal. Patient collapsed for some hours. Slight rise of temperature on third, fourth, and fifth days; lochia offensive. Cervical culture gave growth of *S. salivarius* and staphylococci.
3. Caesarean section; normal puerperium.
4. Caesarean section; normal puerperium.
5. Severe tear of perineum; normal puerperium.
6. Severe tear of perineum; normal puerperium.
7. Normal labour; temperature slightly raised in puerperium; haemolytic streptococci not found in cervix.
8. Severe pyelitis of pregnancy; secondary anaemia, red blood corpuscles 2,400,000 per c.mm. Placenta praevia. Transverse lie; artificial rupture of membranes; later, internal version. Temperature slightly raised in puerperium, maximum 100° F. on fifth and seventh days. No streptococci found in cervix.
9. Concealed and external ante-partum haemorrhage; artificial rupture of membranes, vagina plugged; puerperium normal.
10. A multipara with contracted pelvis. Interspinal diameter 9 in., intercrural 10 in., external conjugate 6½ in. Transverse lie; external version; difficult delivery with forceps after long second stage lasting six hours. Normal puerperium.
11. A case of severe post-partum haemorrhage; manual removal of morbidly adherent placenta. Normal puerperium. Cervical culture showed *Staph. albus*, *B. coli communis*, and *S. salivarius*.
12. Case of ante-partum eclampsia; persistent right occipito-posterior, delivered as such with forceps. Puerperium normal till twelfth day, when rigor occurred; patient developed pyelitis and *B. coli communis* septicaemia. No streptococci in cervix or blood on repeated examination.
13. A case of severe post-partum haemorrhage. Manual removal of placenta performed. Normal puerperium; cervical swab sterile.

No case has yet occurred, so far as is known, of a woman, sensitive to toxin, who has harboured the *S. pyogenes* in her genital tract without developing puerperal fever. Since the observations recorded above a morbid puerperium has occurred in a woman, who failed to react to toxin, from whose cervix the *S. pyogenes* was isolated. This woman, when tested three weeks before delivery and again at the time of delivery, was suffering from suppurating scabetic sores of the hands and feet. These sores may well have been infected with pyogenic streptococci. Unfortunately cultures were not taken.

The conclusion that toxin-sensitiveness indicates susceptibility to puerperal sepsis is not disturbed by this observation, however. There seems no reason to doubt the existence of a degree of resistance to *S. pyogenes* infection sufficient to neutralize the dose of toxin employed for

intradermal inoculation and to prevent a severe septicaemia, but insufficient to prevent a local infection of the uterus; just as every grade of susceptibility to scarlet fever or tonsillitis is well recognized.

No skin tests on women actually suffering from puerperal fever have been made, but it is hoped to undertake these as opportunities arise. A fatal case of *S. pyogenes* septicaemia in a man, recently tested, proved vigorously toxin-sensitive. In a few instances toxins prepared from strains of *S. pyogenes* from puerperal sources have been tested simultaneously with the standard scarlatinal toxin, and so far with the same results, thus supporting Okell's findings.

It is realized that one hundred cases are insufficient to afford conclusive proof of the significance of the toxin test. The investigation is being pursued, therefore, and it is hoped soon to have further evidence. Finally, it may be stated that the possibilities of the toxin-sensitive test as a guide to preventive treatment against *S. pyogenes* infections have not been overlooked. If the conclusions reached receive support, the time may come when prophylactic immunization of toxin-sensitive women will be practised as a routine. But the indications for such immunization, the optimum time in relation to labour, the means employed—by active dosage with toxin or by passive immunization with antitoxic serum—have yet to be studied.

#### Summary.

1. Of 100 pregnant women, 27 were sensitive to a dose of 1/5 c.cm. of a dilution of 1 in 1,000 scarlatinal toxin injected intradermally.

2. Eight, or 30 per cent., of the "toxin-sensitive" women experienced morbid puerperia. From the cervixes of those examined a pure growth of *S. pyogenes* was obtained. Labour was altogether normal in 6 of these cases and normal in the remaining 2, except for slight post-partum haemorrhage.

3. Of 100 pregnant women, 73 gave no reaction to scarlatinal toxin; two of these exhibited morbid puerperia (British Medical Association standard), but in neither case could streptococci be found in the cervix or blood.

4. Thirteen of the non-reacting women, or 19 per cent., sustained difficult labours but healthy puerperia; 6 of these were examined bacteriologically, but in no case was *S. pyogenes* found.

#### Conclusions.

1. The optimum dose of scarlatinal toxin for intradermal test is 1/5 c.cm. of a dilution of 1 in 1,000 strength.

2. Women who react positively to intradermal inoculation of scarlatinal toxin are more liable to develop puerperal sepsis than non-reactors.

3. Difficult labour, with or without laceration, predisposes to puerperal infection only in so far as the risk of introduction of *S. pyogenes* is thereby increased, provided an external source of infection be present.

The work was carried out during the second year of my tenure of the Lawrence Scholarship at St. Bartholomew's Hospital. My thanks are due to Dr. R. R. Armstrong for active collaboration and advice throughout the inquiry.

## A YELLOW FEVER VACCINE.

BY

EDWARD HINDLE,

BEIT MEMORIAL RESEARCH FELLOW IN TROPICAL MEDICINE.

(From the Wellcome Bureau of Scientific Research.)

THE urgent necessity of some method of protective vaccination against yellow fever has been strikingly demonstrated by the occurrence of epidemics of increasing severity in West Africa, and also by the recent tragic deaths of three distinguished investigators from this disease. Consequently it seemed of interest to see whether a protective vaccine could be prepared by using any of the methods employed in the case of other diseases caused by filterable viruses, and in particular those recommended by Todd (1928) for fowl plague, Laidlaw and Dunkin (1928) for dog distemper, and Bedson, Maitland, and Burbury (1927) for foot-and-mouth disease.

The strain of yellow fever employed was isolated from a case at Dakar, and has been maintained by passage in rhesus monkeys and mosquitos until the present time (see Sellards and Hindle, 1928). Although the minimal dose of virus has not been estimated the subcutaneous inoculation of 0.0001 gram of the liver of an infected monkey produces death in four to five days, and sixteen monkeys have been inoculated with the virus, with fatal results in every case. The results of Stokes, Bauer, and Hudson (1928) in West Africa have also shown that the infection is almost invariably fatal in rhesus monkeys, and therefore in the following experiments the possibility of natural recovery from the disease need hardly be considered.

#### Formalinized Vaccine.

Part of the liver and spleen of monkey H 10, which had died from the disease, was ground up in a mortar with broken glass, and the resulting paste mixed with five parts its weight of normal saline, to which was added sufficient formalin to make a strength of 1 in 1,000 formaldehyde. The emulsion was filtered through muslin and kept in the ice chest at 0° to -5° C. until used. This vaccine has been tried on only one monkey, with the following results.

Rhesus H 13 was inoculated subcutaneously with 1 c.cm. of formalinized vaccine on April 19th, 1928. It showed a rise of temperature of two to three degrees on the fourth and fifth days, but no other obvious reaction. On April 27th it was inoculated subcutaneously with 0.2 gram of infected liver from monkey H 11, which had died from the

disease, and after an incubation period of three days had a mild attack of yellow fever, with four days of fever followed by a subnormal temperature and then a return to the normal. Two untreated control monkeys, inoculated subcutaneously at the same time, one with 0.001 gram and the other with 0.0001 gram of the liver of monkey H 11, died of yellow fever after five and five and a half days respectively.

This vaccinated monkey was again inoculated on May 24th with approximately 1 gram of liver material from an infected monkey, and again showed nothing more than a slight febrile reaction, which was probably the result of the large dose administered. Further experiments with this vaccine are in progress.

#### Phenol Glycerin Vaccine.

Part of the liver and spleen of the same monkey (H 10) used in the preparation of the above-described vaccine was treated in a different manner. The organs were cut up into small pieces and washed well with normal saline in order to remove all traces of blood. The tissue was then ground up in a mortar with broken glass, and the resulting paste mixed with four times its weight of the following mixture:

Glycerin	...	...	...	...	600 c.cm.
5 per cent. phenol	...	...	...	...	100 c.cm.
Distilled water	...	...	...	...	300 c.cm.

The emulsion was then filtered through muslin and kept at room temperature for seven days, after which it was placed in the ice chest. This vaccine has been tested on seven monkeys, with the following results.

Rhesus H 12. This monkey was inoculated subcutaneously on April 19th, 1928, with 1 c.cm. of phenol glycerin vaccine which had been kept in the ice chest for twenty-four hours, and, except for one day, when it had a poor appetite, the animal showed no reaction as a result of the inoculation. Eight days later it received a subcutaneous injection of 0.2 gram of infected liver material from monkey H 11, but showed no reaction. Six days later it was again inoculated with 1 gram of infected liver, and on May 24th, five weeks after vaccination, received yet another inoculation of 1 to 2 grams of liver material from two monkeys which had died from the disease.

This monkey, therefore, has been inoculated on three separate occasions with enormous doses of the virus, but in no case was any rise in temperature observed, and the animal has remained in perfect health.

These results were so favourable that it was decided to

put this vaccine to as severe a test as possible in order to see whether its use could be recommended for protection against yellow fever.

On May 15th six rhesus monkeys were each inoculated subcutaneously with 1 c.cm. of vaccine which had been kept in the ice chest for four weeks. None of these animals showed any febrile reaction, although, as usual, their temperatures were taken every morning and evening.

On May 24th these six monkeys, and also four untreated controls, were each inoculated with approximately 1 gram of infected liver material from two monkeys that had died of the disease, one only four days after inoculation. In order to eliminate any personal equation, the inoculations were kindly performed by Dr. C. M. Wenyon, who was unaware which of the monkeys had been vaccinated and which were controls.

All the controls died of yellow fever with typical symptoms, one after four days, two after four and a half days, and one after five days.

One of the vaccinated monkeys which had received a double dose of the virus—about 2 grams—also died of yellow fever, but the other five monkeys have remained uninfected.

In view of the enormous doses these animals received it is evident, therefore, that phenol-glycerin vaccine, prepared from the liver and spleen of infected monkeys in the manner indicated above, is likely to afford a simple means of protection against yellow fever in human beings. Further work is in progress on the duration of the protection in monkeys, and also on the length of time the vaccine will maintain its efficiency.

In conclusion, I should like to express heartiest thanks to Dr. C. Todd for many helpful suggestions, and to Dr. C. M. Wenyon, F.R.S., for providing me with accommodation, and also for much valuable assistance.

## TWO CASES OF HAEMATURIA CAUSED BY INSULIN TREATMENT.

BY

R. D. LAWRENCE, M.D., M.R.C.P.\*

AND

A. S. HOLLINS, B.A., M.B.,

KING'S COLLEGE HOSPITAL.

So few cases have been recorded in which haematuria has been produced by insulin injections, or at least occurred during insulin treatment, that the following two cases seem worthy of mention.

## CASE 1.

A youth, aged 19, developed mild diabetes in August, 1927. This was easily controlled by diet without insulin until he developed severe tonsillitis and pharyngitis on November 7th. He was admitted to hospital at midnight on November 9th in a precomatose condition. He received 120 units that day, which completely abolished the glycosuria and reduced the ketonuria to the merest trace. On November 10th and 11th he received 50 units a day. In the urine passed at noon and in the evening of the 11th a considerable amount of blood was present—smoky appearance and red deposit. The blood was much less on the morning of the 12th, had almost disappeared at noon, and in the evening not a single red blood cell could be found. Again three days later (November 15th) blood appeared in the noon and evening samples of urine, but had disappeared by the next morning, and never returned. On November 17th the insulin was gradually reduced, and was discontinued altogether a fortnight later.

Throughout his period in hospital the urine contained no other abnormal constituent, albumin and white blood corpuscles appearing only when the blood was present and in commensurate amounts. The kidney function tests were normal, and casts absent. There was no history of previous haemorrhages in the patient, nor a family diathesis. He had a perfectly compensated mitral lesion due to previous rheumatism, but no other disease complicating the diabetes. The pharyngitis (pneumococcal) was almost better when the first attack of haematuria occurred and

quite better at the date of the second. The insulin used was Burroughs Wellcome's, and was being used on other patients without producing haematuria. No drug which might have produced haematuria was given.

## CASE II.

A boy of 18, a severe diabetic, was admitted to King's College Hospital on March 5th, 1928, very emaciated and in a condition of severe ketosis. Slight proteinuria was present, probably as a result of the ketosis, because it disappeared when the glycosuria and ketosis were cleared up by large doses of insulin. On the sixth day of insulin treatment (25 and 18 units morning and evening) an obvious haematuria occurred in the specimen of urine passed at noon, four hours after the morning dose. Slight proteinuria and a few white blood cells were present, strictly commensurate with the amount of blood, and no casts were seen. A few red cells were present in the urine passed at 6 p.m. After this no further haematuria or proteinuria occurred. The kidney function tests—blood urea and urea concentration tests—were entirely normal. At the time of the haematuria a slight ketonuria was present (negative ferric chloride test), but much less than on the few days following admission. No septic focus was discovered and no drugs other than insulin were given.

Only seven cases of haematuria occurring during insulin treatment seem to be recorded in the literature. The condition must therefore be very rare, as it is not likely to be overlooked in a diabetic. All except our own two cases have occurred during the earlier days of insulin treatment—in 1923 and 1924, when impurities in the insulin were more frequent, especially abroad, and might have accounted for the haematuria. Thomson<sup>1</sup> mentions two cases in 1923, but gives no details except that they were on large doses of insulin. Henderson<sup>2</sup> also records two cases in 1923, in diabetic men aged 32 and 59, with no evidence of kidney disease and no complications; and another in a boy admitted in coma, in which case a few hyaline casts were present. The haematuria lasted only one day. Gudemann<sup>3</sup> reports two cases; one of a man aged 50, who, after having been on insulin continuously for some months, suddenly commenced to have attacks of haematuria, which disappeared when the insulin was discontinued and reappeared whenever insulin was administered. This case was complicated by tuberculosis of the lungs, and arterio-sclerosis was found in the kidneys at necropsy. His second case of haematuria was also complicated by tuberculosis. Haemorrhages from other parts of the body have been recorded<sup>4</sup> as occurring from the use of insulin—intestinal haemorrhage, cerebral haemorrhage, and two cases of death in coma, in which meningeal and lung haemorrhages were found. In these latter cases, however, there is no real evidence that the haemorrhages were caused by the insulin and were not merely incidental to its administration.

An analysis of all the few cases of haematuria in which any details are published does not reveal any common factor which would explain the occurrence of the haematuria occasionally produced by insulin. These were all, however, on large doses of insulin, and no case seems to have arisen where only small doses of insulin were being used. Concurrent infections were present in some cases, but not in all. The records are not detailed enough to gather whether a heavy ketosis was present in all the cases—an important factor, because it is well known that the excretion of ketone bodies will irritate the kidney at least to the extent of causing some protein and casts to appear temporarily from an otherwise normal kidney. Under such conditions insulin might be more likely to produce haematuria. In our cases ketosis had been severe, but had almost disappeared by the time of the first attack of haematuria, and was completely absent at the time of the second. Curiously enough all the cases recorded so far have occurred in males. It seems to occur both in the old and the young, so that arterio-sclerotic changes in the kidney have probably little to do with the production of haematuria by insulin.

Most of these attacks of haematuria have been trivial and of short duration, and have caused no inconvenience, except some alarm, especially to the doctor. There seems no reason, therefore, from the practical point of view, for discontinuing insulin either temporarily or permanently where it has caused haematuria.

## AMBULATORY TREATMENT OF VARICOSE ULCER.\*

BY

ROBERT GIBSON, M.D.,

HONORARY DERMATOLOGIST, SALFORD ROYAL HOSPITAL;

AND

ALEX. R. SOMERFORD, M.B.,

ASSISTANT MEDICAL OFFICER, MANCHESTER ROYAL INFIRMARY.

VARICOSE veins are met with in men and women in all grades of society, but varicose ulcer is almost entirely confined to the wives of working-class men—women who, as a rule, have had large families, and who have to work all the waking hours all the days of their lives. So injured are some of these women to the pain that they hesitate to have the ulcer healed lest some other and greater misfortune should overtake them.

Our experience, gained during the past twelve months, shows that most ulcers of the leg can be healed, and over 90 per cent. can be cured; it favours a special clinic for ulcers of the leg, since it is difficult to give these patients the attention they require in the ordinary course of a mixed clinic.

In each case of chronic ulcer a complete history is taken and a description of the ulcer is recorded for future reference. The Wassermann reaction is always determined, and should this be positive appropriate treatment is given. Varicose veins are treated by injection, and their cure has rendered the prognosis for varicose ulcer much better than formerly.

## INJECTION OF VARICOSE VEINS.

This operation is performed in the out-patient clinic; and the following solutions are used.

1. Quinine hydrochlor.	...	...	...	4 grams
Urethane	...	...	...	2 grams
Aqua dest.	...	...	...	30 c.cm.
2. Sodium salicylate	...	...	...	111 grains
Novocain	...	...	...	5 grains
Aqua dest.	...	...	...	444 minims

The initial dose of either of these is 1 c.cm., and if no idiosyncrasy is observed 2 or 3 c.cm. can be injected at future sittings; it is advisable that 1 c.cm. should be given at each puncture, and at intervals of about two inches on the vein. The injections are given weekly.

**Technique.**—The patient is seated at a convenient height with the foot of the leg to be treated on a rest. The site for the injection is painted with iodine, and a tourniquet is applied above the selected site. When the needle of the syringe has been introduced into the vein the tourniquet is released and the forefinger of the left hand is placed on the distal side of the needle to compress the vein, the middle finger being used to compress the vein above the needle. The middle finger is then firmly separated from the forefinger so that the underlying vein will be emptied. The injection is made and, before the needle is withdrawn, a pad is so placed that compression will prevent the solution from passing along the needle tract. The fingers and pad are kept in position for three to four minutes, after which they are released and collodion is applied to the puncture.

It is not advisable to inject veins very near the ulcer, lest infection of the thrombus supervenes. Hard edges of ulcers are freely scarified, and if, as frequently happens, there are aneurysmal dilatations on the veins immediately above the ulcer, they should be opened and allowed to bleed empty. Following scarification a dry gauze and wool dressing is applied for twenty-four hours.

The "ulcer and leg" is now dressed with Unna's zinc-gelatin, which dressing is kept on for one week; at the end of this period the dressing is removed, the leg is cleansed, and a new dressing is applied. The formula for the zinc-gelatin is:

Zinc oxide	...	...	...	10 parts
Gelatin	...	...	...	6 "
Glycerin	...	...	...	14 "
Aqua	...	...	...	24 "

This forms a stiffer dressing than the usual formula for this preparation and is strongly recommended.

**Technique.**—The patient is seated at a convenient height and the foot is placed on a rest. The zinc-gelatin, warmed to make

\* Read before a meeting of the Lancashire and Cheshire Branch of the British Medical Association.

it liquid, is painted on the leg and ulcer with an ordinary paint-brush and a gauze bandage is applied—two or three layers of bandage are employed. It is important to note that the entire ulcer is covered with the dressing, no window being left.

Those who have not tried this dressing often object to a discharging ulcer being covered, but it can be done with confidence, and though the ulcer may, as frequently happens, be bathed with pus, when the dressing is removed the edges of the ulcer will show a tendency to heal, which will eventually go on to complete cure. Such a procedure will rapidly cure varicose ulcers.

A word of warning is necessary with regard to the injection of very small varices which are met with in many patients. If such cases are injected the patient should be put to bed for twenty-four hours following the injection, since swelling ensues, and gangrene with the formation of a slow-healing ulcer is liable to occur.

We have during the past twelve months treated nearly seventy ulcers, with marked success in every case. Ulcers of long standing—in one case of twenty-three years—have healed, and still remain so. Patients are asked to report at regular intervals after discharge, so that we may observe the result.

## THE TREATMENT OF PROGRESSIVE MUSCULAR ATROPHY BY PARATHYROID, CALCIUM, AND VITAMIN D.

BY

T. H. THOMAS, M.R.C.P.,

CAPTAIN I.M.S.

By the administration of parathyroid extract, calcium, and vitamin D recently in the Presidency General Hospital, Calcutta, results have been obtained in two cases of non-infective progressive muscular atrophy which, while they have not attained a degree exceeding mediocrity, perhaps, are nevertheless striking and gratifying.

The method of treatment employed at the outset was the hypodermic injection of parathyroid extract 1/10 grain daily, together with cod-liver oil 1 ounce twice daily by the mouth, and calcium chloride in solution 15 grains three times daily. Later this treatment was modified: ampoules were substituted for the tablet form of parathyroid extract, colloidal calcium took the place of calcium chloride, and osteolin, 4 minims twice daily, was given in addition to the cod-liver oil.

## CASE I.

The first patient, admitted on November 26th, 1927, was an Anglo-Indian, aged 34, who gave a history of sixteen years' duration of gradually progressing muscular weakness and wasting. This case was clinically of the pure lower motor neuron type, weakness and wasting being especially marked in the ulnar muscles of both hands and forearms, the biceps and triceps of both sides, the muscles uniting the scapulae to the spinal column, the muscles of the back, and the anterior tibial muscles with marked foot-drop. Weakness without appreciable wasting was present in the hamstring muscles of both sides. A somewhat remarkable feature of the case was excessive wasting of the sterno-mastoid muscles, amounting to almost complete absence. With the exception of the sterno-mastoids all the muscles reacted to faradism. The gait consisted of a peculiar goose-step, owing to the weakness of the hamstrings and the foot-drop. There was considerable lordosis; the patient had to be assisted to his feet, and could not walk unaided.

The treatment above outlined was begun on December 12th, 1927. About three weeks later he surprised all concerned with the statement that he was improving. It was found, however, that he could dorsiflex both feet just a fraction of an inch. Further slow progress occurred, and at the present time he can approximate his scapulae in the mid-line posteriorly with the hitherto completely paralysed rhomboid muscles, exert quite an appreciable grip with both hands, and can flex and extend both arms at the elbow against some slight resistance, which he could not do previously. He sits more erect in a chair, and there is unquestionably great improvement in general health and muscular tone. There is but little change in his gait, though he walks with greater steadiness, and has somewhat greater facility in lifting his toes from the ground.

## CASE II.

In the case of the second patient, a European aged 40, admitted on January 5th, 1928, the progress of the disease had been far more rapid, the first sign of weakness having occurred less than three years previously. This was a case of amyotrophic lateral sclerosis with profound wasting and *main-en-griffe* deformity of both hands, with ankylosis of the metacarpophalangeal joints. There was extreme general wasting and spastic paralysis of the

bulbar muscles; the palatal reflex was absent. Swallowing was very difficult, and the jaw hung pendulous; liquid food had to be placed inside the mouth and was slowly gulped down. This was succeeded by fits of coughing when the food proceeded towards the air passages. The wasting of the intercostal muscles was extreme, and respiration was a painful process. To add to the patient's discomfort there was a troublesome laryngitis and bronchitis, giving rise to an incessant gagging noise on respiration. The patient was entirely helpless, and beyond straightening out his legs when they were flexed he could scarcely perform any voluntary movement. He could shake his head for "no" and say "ah" for "yes," otherwise he was incapable of speech. He was naturally regarded as being very near his end.

Within ten days of his starting the treatment his wife stated that she noticed an indefinable improvement in his condition, and within a month definite changes for the better had appeared. The patient was with some difficulty able to approximate his lips and to raise his head from the pillow, and could swallow his food without inconvenience. A conversation could be carried on with him with a certain amount of difficulty. At the present time he cannot phonate well, but he can form even three-syllabled words with his mouth, and it is quite easy, if one has patience, to understand what he has to say. The most remarkable advance, however, has occurred in the use of his jaw muscles. He can now chew his food without any difficulty and swallow quite easily. Another unquestionable improvement is manifest in the use of the lower limbs, for he can now flex and extend both legs at the knee-joint, and can also dorsiflex both feet.

The general nutrition of this patient has improved remarkably. The weight has not been recorded owing to the discomfort weighing would have caused, but the improvement has been visible. On admission he gave the impression of being in imminent danger of death, and the change for the better is beyond all doubt.

These clinical observations appear to indicate that there is an element in the treatment which is concerned most closely with nerve-cell metabolism. It will be noted that in both the cases atrophy had proceeded to such an extent that complete recovery could not be expected, for in the first there was a sclerosis of neural tissue extending over a period of sixteen years, and in the second a progress to almost the terminal stages of the disease in a relatively short period. There is no doubt that in early cases in which wasting has only just commenced, and where fibrillation is still active in the weakened muscles, something approaching a complete cure might be expected. Even in severe cases it appears feasible to suppose that the onward progress of the disease may be arrested.

There is a group of cases of quite another nature in which a trial of this form of therapy would appear to be justified. I refer to the group of mental illnesses, and especially to dementia praecox, in which the whole symptomatology from the beginning to the most distressing end argues a cell atrophy which, invisible and molecular though it may be, is nevertheless sufficient to cause complete disintegration of the higher association tracts. Paranoia might almost be included in the same category.

I have to thank Major E. O'G. Kirwan, I.M.S., the surgeon-superintendent of the Presidency General Hospital, Calcutta, for permission to refer to the cases concerned.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### LIGATURE OF THE INNOMINATE ARTERY FOR INNOMINATE ANEURYSM.

In the *British Journal of Surgery* (vol. ix, No. 35) Sir Charles Ballance collected the recorded cases of ligature of the innominate artery; he writes: "All the cases recorded in the following paper, except my own, are of ligature of the innominate for subclavian or carotid aneurysm." His own cases comprised four, of which two patients died shortly after operation, one died two and a half years later, and the remaining one could not be traced. Aneurysm of the innominate artery cured by proximal ligature of the artery is therefore sufficiently uncommon to make the publication of the present case of interest; it is, moreover, the first successful case to be reported from Leeds.

A man, aged 37, received in 1918 a bullet wound at the root of the neck on the right side immediately above the centre of the clavicle. The bullet was removed at a casualty clearing station from just above the inner end of the clavicle, and the wound rapidly healed; but a small hard swelling remained at the

site of entry, and another as large as a small egg in the notch above the manubrium sterni. Since being wounded he has had a husky voice and frequent attacks of pain in the neck, and headache without vomiting. In 1925 he suddenly lost the vision of the right eye, which partially returned later.

A week before Christmas, 1926, the central swelling began to enlarge rapidly, and this was accompanied by much pain both at this place and in the back of the neck. He was admitted to the Ministry of Pensions Hospital in Leeds in January, 1927. There was a tender pulsating swelling as large as a big pear filling the notch above the sternum and extending in an ill-defined manner to both sides of the neck; the central part of this swelling was purple in colour and almost as thin as tissue paper. He complained of pain in the root of the neck, in the occipital region, and behind both ears. There was difficulty in swallowing, especially fluids. The right pupil was contracted, and the right radial and carotid arteries could only be felt pulsating feebly; the huskiness of the voice was found to be due to right recurrent laryngeal paralysis. There were no sensory changes in the hand or arm. He was short of breath, had a pulse of 92, and a temperature of 99.4° F. As the swelling was rapidly increasing in size I decided to operate without delay, and performed the following operation on January 24th, 1927.

The manubrium sterni was removed after carefully separating the thin aneurysmal sac, which was closely adhering to the upper border. The aneurysm was found to spring from the innominate at its bifurcation, leaving rather less than half an inch of the main trunk intact at its origin from the aorta. A ligature of No. 2 chromic gutgut was passed round this part of the innominate and tied with sufficient tension to approximate the walls closely. The recent acute symptoms were obviously due to a leak in the upper and right side of the sac. The clot was turned out, when vigorous bleeding occurred from the distal end of the subclavian. A finger was applied to the open mouth while sutures were being inserted on the inner side of the sac; after tying these all haemorrhage stopped. It was impossible to obliterate the greater part of the sac, and inadvisable to attempt removal, as it was firmly adherent; it was therefore packed.

The patient stood the operation remarkably well, but the wound took some weeks to heal completely, owing to the packing. The right arm was useless at first, but has since fully recovered, though there is, of course, no radial pulsation. When last seen, in June, 1927, he was very well, with no sign of recurrence. All that remained was a small hard mass where the aneurysm had been, and a depressed scar at the place from which the manubrium sterni was removed. He has, of course, still the huskiness of his voice, and vision is limited to the central part of the field, in which he can only distinguish objects rather mistily. He is quite free from pain.

E. R. FLINT, F.R.C.S.,  
Assistant Surgeon, Leeds General Infirmary.

#### ACUTE APPENDICITIS FOLLOWING TYPHOID FEVER.

THE relation between acute appendicitis and typhoid fever has always been an interesting point and the cause of some confusion in diagnosis. Acute appendicitis following typhoid fever must be a rare condition—I have no means here of verifying this—and the following case may prove of more than ordinary interest.

A young man was admitted to the Colony Hospital, Grenada, on April 21st, 1927, with a history of four days' continued fever. His doctor regarded him as a case of suspected typhoid fever, but was doubtful of the diagnosis, as there was an old history of (?) malignant malaria in Demerara several months previously. He was isolated and kept under observation, and eventually was notified as a positive typhoid case five days later. His illness ran a typical course up to the twenty-fourth day, a deferrescence by lysis having occurred. On the evening of this day (May 10th) his temperature suddenly rose to 100.6° F., with pulse rate quickened to 114, and he began to complain of acute abdominal pain. It is noteworthy that his pulse rate ranged from only 76 to 100 during the height of the typhoid fever.

I ordered a soap enema and the result was copious, but there was no relief from the pain; he was slightly distended. Palpation of the appendix region revealed a well-defined enlarged appendix with bulbous extremity, which was tender. The matron of the hospital palpated the appendix and could make out its outline distinctly. On the morning of May 11th I operated, and removed an acutely inflamed appendix with, as we had expected, an enlarged tip; it was adherent in its whole length to the caecum. The wound healed by first intention, and though the patient ran a temperature for some eight days afterwards his recovery was uneventful and he had no more pain.

The patient's prolonged convalescence was entirely due to his enteric condition. No blood counts were performed during his typhoid phase nor at the occurrence of the appendicitis; they might have been of interest, but the abrupt acceleration of the pulse rate was significant. I regard this as a genuine case of appendicitis occurring at the end of the third week of typhoid fever, and the wonder is that there are not more instances of the same condition to record.

V. L. FERGUSON, M.B., Ch.B.  
St. Lucia, British West Indies

## Reports of Societies.

### MATERNAL MORTALITY DUE TO PUERPERAL SEPSIS.

At the meeting of the Edinburgh Obstetrical Society on May 8th, with the president, Dr. HAIG FRANKSON, in the chair, Dr. JAMES YOUNG read a paper entitled "Maternal mortality from puerperal sepsis: an analysis of the factors of contagion, trauma, and auto-infection," which is published at page 967.

Dr. FORDYCE, in the discussion following this paper, regarded the question of segregation of confinement cases in hospitals as an important one, and doubted whether it was advisable for normal cases to be confined in hospitals where there was only a limited amount of space. He thought that forceps delivery in selected cases prevented the trauma which might otherwise be caused by a very delayed labour. He regarded the statistics of puerperal sepsis of one hundred years ago as not very reliable.

Professor HENDRY referred to three cases of pyrexia due to extraneous origins—namely, infective rhinitis, commencing whitlow, and a septic wound on the skin of the patient's husband; these showed the importance of contagion. He supported very strongly Dr. Young's principle of separate accommodation in maternity hospitals for cases sent in after intervention outside. With regard to trauma, primigravidae seemed to be more liable than multiparae.

Dr. MILLER showed by statistics of the Royal Maternity Hospital that the incidence of pyrexia in patients delivered instrumentally was much larger than in those whose delivery had been spontaneous. He had found a marked variation in the bactericidal power of the blood in pregnant women, which might explain the variation in individual susceptibility to infection.

Dr. J. M. BOWIE regarded trauma as of great importance in puerperal sepsis. He thought that the whole machinery of maternity service in this country needed overhauling. Reorganization might be effected in two ways: (1) by the present system of trained midwives working alone in normal cases and assisted by doctors in difficult cases; or (2) since midwifery work appealed to many doctors a new race of specialists might rise, who would confine themselves to it.

Dr. KEEPLE PATERSON attributed great merit to prolonged antiseptic douching after delivery even in normal cases, but thought it of greater value after manipulative intervention.

The PRESIDENT thought that haemolytic streptococci might be rendered temporarily inert by the normal vaginal secretion, but in certain circumstances they might regain their haemolytic action. He urged the segregation of complicated cases, but to do this a large hospital was required. He did not think that trauma was only due to instrumental intervention, since normal labours were often associated with very severe trauma. He considered the co-operation of midwives and medical practitioners an excellent practice.

#### Clinical Reports.

Dr. CHARLES GRAHAM described in detail ten cases of Caesarean section which he had performed for various indications, such as contracted pelvis, eclampsia, disseminated sclerosis, and an impacted transverse lie. Attention was drawn to the number of cases of Caesarean section coming under the notice of a busy country practitioner. His results had not been attended with any maternal mortality.

Dr. C. W. SOMERVILLE described three confinements which were complicated by measles, encephalitis lethargica, and diabetes respectively. In the case of measles the patient developed the disease at the onset of labour, which however, passed off normally with the aid of "twilight sleep." The child had no rash when born, and did not develop the disease, although the mother nursed her child for the first two months of its existence. The puerperium was uneventful. The case of encephalitis with labour was also normal with regard to the labour; the encephalitis was of the Parkinsonian type. The child was apparently quite

healthy. The case of diabetes was diagnosed three months before labour was due, and the patient was treated with 60 units of insulin daily until labour started. The labour itself was rather difficult, since the head had rotated into an occipito-posterior position, and the patient had to be kept under light chloroform anaesthesia for nearly two hours before delivery was effected. Chloroform was not feared as the case had been so thoroughly treated with insulin. The mother nursed her child for six months without any detriment either to herself or to the infant.

### NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.

At a meeting in Leeds of the North of England Obstetrical and Gynaecological Society on April 27th, with the president, Mr. H. LEITH MURRAY (Liverpool), in the chair, Mr. J. E. STACEY (Sheffield) described a specimen of bilateral tarry ovarian cysts. Mr. Stacey said that the histological characteristics of the tumours were identical; marked hyperaemia and production of numerous capillaries were a feature of the sections. The cavity was lined in patches with a poor type of columnar epithelium, which gave place in some areas to a more endothelial-like character, and was entirely absent in other parts. Deep to the epithelial layer was a stratum of golden pigmented polyhedral cells with many of the characteristics of lutein tissue cells. Areas of this had been stained by the Prussian blue reaction, and in no part showed the presence of iron. This layer of lutein cells was invaded irregularly by bands of hyaline tissue arranged radially to the cavity of the cyst. In places the cells were separated from one another, producing a mosaic effect; in others they were tightly bunched together. No convolution of the lutein tissue was present in any part of the wall. The characteristics of lutein tissue cells in the walls of these cysts demonstrated their difference from the endometrial cysts described by Sampson, and marked them out as follicular in origin. But for the lack of convolutions and of two distinctly defined types of cell—granulosa lutein and para lutein—Mr. Stacey would have placed this case in the third class of tarry lutein cysts described by Wilfred Shaw—namely, the tarry corpus luteum cyst—since the hyaline degeneration in the wall, a marked feature in this type, was present. But in the absence of these two primary characteristics (convolutions and two types of cells) he classed the case as one of unusually large tarry theca lutein cysts. Mr. Stacey thought that insufficient attention had been paid to Wilfred Shaw's communication to the sixth British Congress of Obstetrics and Gynaecology, held in Manchester in 1927. (Reference was made to this in our columns on May 21st, 1927, p. 924.) A large part of this paper had been devoted to a consideration of tarry cysts of the ovary, and Mr. Stacey suggested that endometrial implantation cysts had very often been mistakenly so called when really they were of follicular origin. Shaw's three types were the tarry theca lutein cysts, the tarry granulosa lutein cysts, and the tarry cysts derived from corpora lutea. Each of these types had been described as possessing characteristic features, but from superficial resemblances between each Mr. Stacey thought it must require a very large number of sections taken from many parts of an ovary, and even many areas of the wall of the same cyst, before it was possible to place accurately any tarry cyst in its right group. Moreover, tarry cysts of more than one type had been found in the same case, and in one specimen described by Shaw, complicating matters still further, an endometrial cyst of Sampson had been associated with a tarry theca lutein cyst. Naked-eyo appearances in no way helped in the diagnosis between endometriomata and tarry cysts of follicular origin. Sampson had described no endometrial cyst as large as the follicular tarry cyst here recounted, but this was no criterion, since Dougal in 1925 had reported one 10 inches in diameter. In the case related the anatomical and clinical features were identical with many another case described as endometrioma, and only a careful histological examination in the light of Shaw's and other recent papers had determined the correct origin of the

tumours. In Sampson's description of endometrial cysts he said that in the final condition there was very little left of the lining of the cyst beyond a few irregular cubical cells; deep to this was what remained of a differentiated layer of stroma, and, when this was present, large pigmented cells were found in it. The surrounding ovarian tissue was converted into a layer of hyaline tissue. This alone was sufficient to show how easy it could be to mistake the two conditions of endometrioma and follicular tarry cysts.

#### *Spontaneous Rupture of Uterine Sarcoma.*

The President and Mr. A. A. GEMMELL (Liverpool) described jointly a case of uterine sarcoma which had ruptured spontaneously, giving rise to acute abdominal symptoms.

A sterile married woman, aged 48, was admitted with the diagnosis of "acute abdomen" to a surgical unit in the David Lewis Northern Hospital, Liverpool, on March 7th, 1927. She complained of acute abdominal pain with nausea and vomiting, and great frequency of micturition. The pain was referred to the lower abdomen, and had been present for a few hours only; the bowels had moved on the morning of admission. She gave a history of vomiting with pain in the right iliac fossa three weeks previously; this soon passed off, and she had been fairly well since. Menstruation had been somewhat irregular, although in no way excessive, for a year previously; for the preceding three months, however, it had been regular. The patient lay in bed with the abdomen much swollen and the left leg flexed. The temperature was normal, and in spite of the pain her pulse was only 80. By catheter 34 ounces of urine were drawn off without relief to the pain. Vaginal examination showed a rounded tender and apparently fixed swelling filling the pelvis. She was accordingly transferred to the gynaecological unit. A diagnosis of ovarian cyst with twisted pedicle was made, but under an anaesthetic the mass was defined as uterine; it seemed probable, therefore, that there was acute, presumably red, degeneration of a uterine fibroid. The patient appeared healthy, with a moderate amount of subcutaneous fat.

At operation the posterior wall of the uterus presented an enlargement filling the pelvis; the mass was lightly adherent at one spot and had burst at its lower pole. There was a small quantity of free blood in the peritoneal cavity, and some absolutely loose fragments, totalling probably half an ounce, in the pouch of Douglas. The peritoneum of the lower abdomen and pelvis showed no secondary growths. A subtotal hysterectomy with removal of both appendages was rapidly performed. The specimen weighed 12½ ounces, and even after removal was judged to be a uterus containing a degenerating fibroid which had burst its capsule. The rupture had occurred over an area of about two square inches: the peritoneal edges were retracted and fully exposed the softish lobulated and apparently oedematous substance of the growth. The tumour was moderately firm—not in any way brain-like—and it was slightly yellowish. Microscopical examination proved it to be a mixed-celled sarcoma (small round cells, spindles, and giant cells) with areas of necrosis. The growth was definitely infiltrative in the muscle, and at no point was any suggestion given of malignant metaplasia of a fibroid. The endometrial cavity lay distinct from the mass and was separated from it by a varying amount of the muscularis. The loose fragments stained well and showed no necrosis. The patient left hospital on March 27th, and pelvic and abdominal examinations were then normal, but on April 15th she was readmitted with symptoms of threatened intestinal obstruction and considerable cystic swelling of the lower abdomen. An exploratory laparotomy released several pints of slightly blood-stained fluid and showed innumerable nodules of malignancy, more particularly in the pelvis, but also in the abdomen. Sections of several of these demonstrated malignancy similar to the original growth. The patient, who had obviously lost much weight since her discharge from hospital nineteen days previously, went downhill very fast, and without any further symptoms of obstruction died on May 12th.

#### *Parovarian and Ovarian Cysts in Pregnancy.*

Mr. W. Gough (Leeds) read notes of a case of parovarian and ovarian cysts removed during pregnancy.

A married woman, aged 32, had had one child four years previously. The last menstrual period finished January 4th, morning sickness began in February and was severe. About the middle of March she felt "a lump" in her left side; there was no pain. Inspection showed a rounded swelling above the pubes passing upwards and to the left more than half-way to the umbilicus. It was softish and fluctuant; behind and to the right a rounded mass was felt deep in the pelvis. On vaginal examination the cervix was found to be very high, placed anteriorly, and continuous with the abdominal swelling; behind it was a hard rounded mass the size of a fist, very slightly movable. It felt so hard that a diagnosis of sacral chondroma had been made. Slight elasticity could, however, be detected, and Mr. Gough had therefore diagnosed a cyst. The tumour was so obviously in the way of delivery that operation was decided on. The tumour proved to be a right parovarian cyst adherent in the pouch of Douglas; there was also a cyst of the ovary, the size of a duck's egg. The appendage and appendix were removed.

Mr. Gough said that the points of interest in the case were:

1. The diagnosis of the nature of the tumour and the reason of its extreme hardness. Rectal examination had proved of value.
2. The question of correct treatment. He had no doubt that in this case operation was the right thing.
3. The after-history. The vomiting continued after the operation as severely as before. He did not place any value on the theory that some cases of hyperemesis gravidarum were reflex in origin, but he was disappointed that there had been no improvement in the condition.

#### *Imperforate Anus.*

Mr. J. W. BUNNS (Liverpool) described a case of "imperforate anus."

A married woman, aged 31 years, had had three normal labours. She complained of the womb "coming down," and much discomfort on walking. On inspecting the anus it was seen that except for a small area of skin the anus was absent. The vulva, including the clitoris, was normal. About one inch inside the vagina on the posterior wall a transverse slit with crenated edges was seen, which opened directly into the rectum. Above this slit there was a well-marked septum, which separated the vagina from the rectum. On bimanual examination the uterus felt slightly enlarged, retroverted, and freely mobile; the tubes and ovaries were normal. The coccyx was missing and the sacrum felt deficient. The tissue between the vaginal orifice and the pigmented area felt very thin. On straining, the uterus and bladder passed outside the vulva. In spite of this condition the patient definitely stated that except on one occasion, when she was in the Maternity Hospital and had been given enperients, she had never experienced any discomfort arising from loss of control over the bowels.

The case presented a distinct problem as to the best line of treatment to adopt so as to cure the proctodia and, if possible, provide a degree of sphincteric control over the rectum. Anterior colporrhaphy was performed and the bladder pushed up. The cervix was amputated by removing a large cone of tissue, and the raw area thus made was covered in by vaginal flaps. Next the lower two inches of the rectum were dissected free and a new anus was provided in the middle of the pigmentation of the skin. The free end of the bowel was drawn backwards through this anus and was united to the skin margins by interrupted catgut sutures. The perineum was then constituted by bringing the lateral tissues together in the midline as in the ordinary perineorrhaphy. At the end of three weeks, when the vaginal wounds had healed, the abdomen was opened, the uterus ventro-fixed, and both tubes cut across, ligatured, and arranged so that the cut ends of each tube were separated by the corresponding round ligament. The patient made a very good recovery from both operations and left the hospital in excellent condition. She had very good control over the bowel and could retain a simple enema.

Mr. BUNNS said that it was somewhat difficult to understand how this control over the bowel had come about. The tissues of which the new perineum was constituted could not have contained much active muscle tissue, and he presumed that the original sphincter ani must have been either absent altogether or else atrophied. The pulling backwards of the bowel might have kinked it so much that abdominal pressure was required to overcome the obstruction, and so a certain amount of control was acquired indirectly.

#### *Placenta Accreta.*

Mr. A. Gough (Leeds) described a case of placenta accreta.

A primipara, aged 26, had delay in the second stage of labour; the child was easily delivered with forceps. It was then noticed that there was no loss of blood, and only after three hours did there appear a slightly blood-stained discharge. There was no descent of the umbilical cord. After-pains occurred, but the uterus did not contract as usual into a hard round ball. Pituitrin and ergotin were given, and attempts were repeatedly made to express the placenta, but without success. Having recently heard of two disasters following the removal of very adherent placentas—one patient dying immediately from shock and haemorrhage, the other a few days later of septicaemia—Mr. Gough decided to leave the placenta in the uterus and to await events. The cord hanging from the vulva was kept dusted with boric powder. Next day there was no change, and the temperature remained normal; Credé's method was again tried without success. On the third day the temperature was 100° F., but the patient's condition was otherwise satisfactory; attempts to express the placenta again failed. On the fourth day the temperature had risen to 102.8°, and there was general malaise. The lochia were of average amount and not offensive. It was then decided to empty the uterus. Under ether anaesthesia the placenta was found to be adherent in one or two places, but it was readily removed. The uterine cavity was washed out with copious irrigations of a 1 in 300 solution of

lysol. The temperature rose to 103.5° F., but on the next day had fallen to normal and the patient made a good recovery. Soon afterwards, however, signs of pulmonary tuberculosis appeared and she spent some months in a sanatorium; this might possibly have had some etiological significance.

Mr. Gough thought it might be questioned whether this was really a case of placenta accreta. It was clearly a morbidly adherent placenta, but perhaps not one of the most adherent. Generally the diagnosis of placenta accreta had been made after an unsuccessful attempt at its manual removal. What was the proper course when the placenta could not be delivered in the usual way? Most English textbooks stated that it must be removed manually after a certain time—one or two hours. Any important post-partum haemorrhage was, of course, an indication for the immediate emptying of the uterus. In this case, with no loss of blood for three hours and then only a minimal loss, the safer course was the one adopted. The forcible scraping away of the placenta in fragments entailed a grave risk of perforation of the uterus, shock, haemorrhage, and the later development of septic complications. A risk of leaving the placenta was, Mr. Gough supposed, that separation might follow and post-partum haemorrhage occur when no help was at hand; but it seemed unlikely that a closely adherent placenta would suddenly become detached. This fear might have some weight when dealing with a patient in a remote country district, but in an institution it could be entirely disregarded. Then there was the risk of sepsis being favoured by the retention: it occurred in this case, but was evidently of the sapraemic type.

#### *Drainage in Wertheim's Hysterectomy.*

Professor FLETCHER SHAW (Manchester) read a paper on the value of drainage in Wertheim's hysterectomy. He said that until recently his mortality from this operation was 20 per cent. Even a mortality of 12 per cent. which Bonney had in his second series was a dreadful responsibility for any surgeon, especially since so many of the patients who did recover had a very painful and prolonged convalescence. He had tried every suggestion for combating shock, sepsis, and urinary sepsis without much improvement until he found that Professor Werner in Wertheim's old clinic in Vienna still drained the pelvis by a small wick of gauze running down into the vagina. In the early days this was the universal practice, but Dr. Shaw had ceased to do this after the first few years, because several patients developed ureteral fistulae, due probably to the fact that a much larger quantity of gauze was left in the pelvis than was done by Professor Werner. Since his visit to Vienna Professor Fletcher Shaw had had the opportunity of performing this operation upon nine patients, all of whom recovered. He admitted that this limited series of cases did not permit dogmatism, but what had impressed him much more than the want of fatalities was the straightforward, easy convalescence of most of these patients. So, although the series was small, he thought he should bring his experience before the other members of the society, since he believed he had gained more improvement from this small step than from any other which had been suggested.

Mr. CARLTON OLDFIELD said that twenty years ago he had employed the gauze pelvic drain. He had, however, discontinued its use, and his results were better than formerly. Mr. MILES PHILLIPS did not use the gauze drain. He considered the most important factor in success following the operation was absolute haemostasis.

### OTO-LARYNGOLOGY.

THE summer meetings of the Sections of Laryngology and Otology of the Royal Society of Medicine were held on May 31st and the two following days. On the first day Mr. J. F. O'MALLEY presided over the Section of Laryngology, and the presidents of subsequent meetings were Mr. H. BARWELL (Laryngology) and Dr. FRASER (Otology).

#### *Vasomotor Affections of the Internal Ear.*

Professor G. PORTMANN (Bordeaux), in a paper on vasomotor affections of the internal ear, said that vasomotor disturbances could be regarded as some of the most impor-

tant pathological elements in internal ear affections; they depended directly on the sympathetic system. Recently, in association with colleagues, he had experimented on the action of the sympathetic in reference to the labyrinth, the experiments consisting of either pericarotid sympathetomy or the injection of vasomotor drugs, compression of the vertebral and common carotid arteries, and the warm bath test. For a long time otologists had been impressed by the action of the sympathetic on the labyrinthine circulation on the one hand, and on the other by the secretion of the endolymphatic fluid. Having observed a typical angiospasm of the anterior labyrinth in a patient with Raynaud's disease, Lermoyez drew attention to the similar structure of the two situations (the digital and the labyrinthine), and summed up a particular labyrinthine affection as "the vertigo which makes one hear"; it appeared to be a spasm of the internal auditory artery. Professor Portmann submitted the following comparative table of the two conditions:

Ménière's Disease.	Lermoyez's Syndrome.
Good hearing.	Good hearing.
Sudden vertigo.	Gradual deafness.
Sudden and decreasing deafness.	Sudden vertigo.
Slow recovery.	Quick return of hearing.

Angiospasm could well explain the onset of vertigo and the disappearance of the deafness, both depending on the removal of the barrier of the labyrinthine artery. The pathogeny of Ménière's disease was still debatable; Ménière's own view was that it was caused by intralabyrinthine haemorrhage, while all who had tried to solve it gave an important place in causation to vasomotor troubles. Many facts pointed to vertigo being essentially a phenomenon of irritation; it disappeared with destruction of the labyrinth; and irritation of the internal membranous ear or of the vestibular nerve was required to produce a giddy sensation. A strident noise by irritating the original filaments of the cochlear nerve might also cause vertigo reflexly through vaso-dilatation. How was this irritation of the vestibular nerve produced? No satisfactory answer could yet be returned to this question, but whatever the mechanism, Ménière's disease was closely connected with vasomotor phenomena, and therefore with the sympathetic equilibrium. Vertigo was produced by the sudden vaso-dilatation following the spasm in the syndrome of Lermoyez, but that which accompanied ischaemia of the labyrinth disappeared on sympathetomy, the consequence of which was a vaso-dilatation of the labyrinth. Deafness seemed to accompany ischaemia of the anterior labyrinth by vaso-constriction. The angiospasmic syndrome of the labyrinth included tinnitus, deafness, vestibular hyperexcitability, sympathetic hypertony. The causes of vago-sympathetic troubles were very diverse, and might be mechanical, endocranial, toxic, or plainly psychic. He attached great importance to the action on the regulating apparatus of the endocrine glands, especially the hormone of the suprarenal gland.

#### *Otosclerosis.*

Dr. LOWNDES YATES read a paper entitled "A working hypothesis for research in otosclerosis." He said he regarded as instances of this condition cases in which Bezold's triad symptom-complex was present with a patent Eustachian tube and no demonstrable adhesive process in the middle ear or evidence of a former perforation of the membrane. From the point of view of audiography he considered that there were three types of ear disease: (1) nerve or internal ear deafness; (2) otitis media with indrawn membrane and limitation of its movements by adhesion to the promontory; and (3) acute otitis media, subacute otitis media; and otosclerosis, in which there could be observed a gradually increasing departure from the graph.

Professor OTTO MAXEL (Vienna), the recipient of the Dalby Memorial Prize, in a paper on the pathology of otosclerosis, said that in this disease the original bone of the labyrinth capsule became absorbed, and bone marrow was formed in which osteoblasts were plentiful; the new bone, thus imperfect in character, overgrew the oval and the round windows. In otosclerosis the lesions were

multiple, and fibromata in other parts could be regarded as distant manifestations of the same process. He had found in these cases a synchondrosis, also bony growths on the petrous bone. In ten out of fifty cases of deaf-mutism examined he had found typical areas of otosclerosis; while in fifteen out of thirty cases of otosclerosis there was a maldevelopment of the inner ear, with anomalies of the cochlear framework. Pathological investigation showed that it was most probably a hereditary disease; he opposed the view that it was inflammatory in origin.

Dr. A. A. GUAY said he agreed with nearly all Professor Mayer's contentions. He believed the disease could only occur in a person who had a personal tendency towards it, though it was not inherited in every case. In further research on the subject not only the temporal bones, but also the brains, should be included in the investigation. Mr. G. J. JENKINS argued that otosclerosis was a different disease from osteitis deformans, and that the former could not be regarded as an atavism, since it progressed, and no atavistic manifestation showed progression. Mr. SOMERVILLE HASTINGS said he had seen cases of what was clinically middle-ear deafness change into good examples of otosclerosis. Mr. J. ADAM (Glasgow) illustrated the multiplicity of lesions which otosclerotics bore by relating those occurring in a family, and including atheroma, scoliosis, kyphosis of the spine, and fragilitas ossium. Sir JAMES DUNDAS-GRAUNT deprecated a hurried diagnosis of otosclerosis, or taking too gloomy a view as to the outlook; he had known cases become stationary, and had even seen improvement in some. The PRESIDENT (Dr. Fraser) demonstrated on the epidiascope histological specimens in which he pointed out, in otosclerotic cases, areas which seemed to be obviously inflammatory, so supporting his view that this disease was of inflammatory origin.

#### *Dysphagia due to Pharyngeal Paralysis.*

Mr. W. M. MOLLISON, in a paper on dysphagia due to pharyngeal paralysis, said that patients frequently presented themselves because of difficulty in swallowing, but this was not often due to paralysis of the pharyngeal wall, yet in the last few years he had seen several such cases. Unfortunately the symptom could not be treated with much chance of success. Complete unilateral paralysis of the vagus caused unilateral paralysis of the palate, pharynx, and larynx, but there was only slight interference with swallowing. When laryngeal paralysis was complete the cord was flaccid, both adductors and abductors being paralysed. It was possible to imagine a small haemorrhage occurring in the middle of the nucleus ambiguus which would damage the fibres to the pharyngeal plexus, and as the effects of the bleeding became localized, the effect might be restricted to the palate, or to the pharynx or larynx. The causes of pharyngeal paralysis could be classified as: (1) central, (2) intracranial, (3) extracranial, and (4) peripheral, such as from diphtheria or lead poisoning. The prognosis in the condition when due to diphtheria was favourable, but it was grave when the disability was caused by progressive muscular atrophy and amyotrophic lateral sclerosis; it was somewhat better in acute bulbar paralysis. Mr. Mollison gave details of the cases he had seen, including two in which the lesion was at the base of the skull, one from a bullet wound there in the war, the other from tuberculous glands.

#### *Intrinsic Cancer of the Larynx treated by Laryngo-fissure.*

Sir STCLAIR THOMSON gave an account of the results in 70 cases of intrinsic laryngeal carcinoma treated by laryngo-fissure. The series extended over twenty-eight years, and he had been able to trace every case. His object at the operation was to remove all the tissue between the subglottic space and the ventricular band, leaving only the external perichondrium. The danger area was, undoubtedly, the subglottic space. Of the 70 patients (only 10 of whom were hospital cases) 34 were still living at periods of three to nineteen years after their operations. There were eighteen deaths from causes other than recurrence of the disease. Two patients died from bleeding because, apparently, they had been given heroin; it was

against his wish and practice that these patients should be given heroin, morphine, or similar drugs. Eleven of the patients developed malignant disease elsewhere than in the larynx; most recurrences took place within the first year. If in borderline cases (in which there was a tendency to exteriorization) there was a recurrence, he advised laryngectomy. He regarded the outlook as grave in subglottic cases, and when there was fixation of the cord: for example, in nine cases in which the cord was fixed, only four patients lived more than three years after operation. It was possible to perform the operation under local anaesthesia; if a general anaesthetic was preferred, the narcosis should not be deep. He neither used cocaine beforehand nor plugged the larynx. He repeated the appeal which had been frequently urged that these cases should reach the laryngologist at that earlier stage when operation was distinctly hopeful.

#### *Miscellaneous Papers and Discussions.*

Mr. A. T. RAKE read a paper on achalasia and degeneration of Auerbach's plexus. He said that the vagus supply preserved the normal oesophageal tone and supplied the cardiac sphincter. A lesion of the vagus nerve fibres disturbed the mechanism of relaxation of the cardia, which must precede the entry of food into the stomach. In some cases of achalasia the plexus was about twice the normal size, the whole structure being infiltrated with small round cells. In the chronic stage there were around the fibrous plexus large blood vessels having thickened walls. He considered the condition inflammatory, not vascular.

Dr. ARTHUR HURST said that in some of the cases of this condition hypertrophy of the cardiac sphincter was found, but not in all. It was, he considered, parallel to Hirschsprung's disease in that there was an absence of normal sphincteric action. Dr. A. BROWN KELLY said the fibrotic changes in cases of cardiospasm were first demonstrated by Dr. Munro Cameron. The speaker thought that degenerative changes in Auerbach's plexus gave rise to inco-ordination of the myotonic reflex in the region involved, and that in consequence the distant longitudinal layer was not reached by stimuli.

Dr. LOWNDEN YATES read a paper on methods of estimating the liability to post-operative haemorrhage from unsutured wounds. He said that in three-fifths of the cases of spontaneous epistaxis he had seen there was a considerable prolonging of the clotting time from six minutes as a minimum to as long as fifty minutes. The administration of calcium did not reduce this. To a patient in this category who also had acidosis he gave sodium bicarbonate, and following that the clotting time became normal; in epistaxis cases as soon as the sodium bicarbonate had rendered the urine alkaline there was a like benefit. When there was a septic focus and this was removed the clotting time again became normal. Not every type of compensated acidosis was associated with an alteration in the clotting time. Examination of the clotting time of blood taken from the ear before operating enabled him to take measures to prevent what otherwise would be trouble from post-operative haemorrhage; moreover, patients who had excessive haemorrhage were more liable than others to secondary haemorrhage afterwards. The latter was often attributed to the surgeon when the fault lay with the clotting time.

Dr. P. WATSON-WILLIAMS, in a paper entitled "Familial infectivity of chronic sinusitis," alluded to the fact that the members of some families seemed to have an inborn predisposition to catarrhal infections. When a child in such a family had chronic nasal sinus infection he usually also had enlarged tonsils and adenoids, and even after these had been surgically removed lymphoid tissue in other regions became infected and symptoms recurred. He showed charts of remarkable families with multiple disabilities of the kind.

Dr. SALISBURY SHARPE, in a paper on the influenza ear, urged that in the hulging brought about by influenza and seen frequently during epidemics of that disease, myringotomy ought to be carried out instead of leaving the swelling to burst spontaneously, since early intervention prevented secondary infection. Haemorrhagic myringitis he regarded as pathognomonic of influenza as the causal agent.

## Reviews.

### MEDICAL ETHICS.

A HISTORY of medical ethics does not at first sight seem a particularly inviting enterprise, nor one at all likely to serve any practical end. Such a conclusion may be that of the natural man, but it is contested by Professor CHAUNCEY D. LEAKE of the University of Wisconsin, and he is not without opportunities. Professor Leake, it seems, has for some material for a historical study of the rules and regulations which have at various dates been accepted as governing, in a scemly fashion, the attitude and conduct of medical practitioners. As a minor contribution to this purpose he now issues a new edition of Dr. Thomas Percival's *Medical Ethics*,<sup>1</sup> a book which first appeared in 1803 and which had in its day considerable success. With Percival's writings he has printed the code of ethics adopted by the American Medical Association in 1847, and revised in 1903 and in 1912. His book is therefore a historical record of professional customs and rules at different dates. But the dates selected are comparatively modern, and they tell us little or nothing of the origins or of the development of medical ethics. Moreover, the interval between Percival's book and the American code is relatively short, and it cannot be said that the later one, as compared with that of earlier date, displays, at least in principle, any decided change. What Dr. Percival wrote more than a hundred years ago is substantially what is taught and practised at the present day. Further, as Professor Leake's ambition is to explore the "origins" of medical ethics, in the belief that such an inquiry will make the subject "better comprehended," his present publication, however interesting in itself, does not much advance his aim. In relation to "origins" it has this cardinal defect—it does not begin at the beginning, for, though there are a few references to earlier authors, the discussion of these is decidedly scanty. Whether the full story, when it is told, will repay the labour involved in the telling remains to be seen.

In the meantime, Professor Leake, in three brief introductory essays, expounds certain general views to which his studies have so far led him. First, as a layman, he expresses deep sympathy with the "commonly stated high ideals of the medical profession," though he laments the tendency of "organized medicine" to resist any attempt "to change its present relation to society." What change he desires is not very evident beyond the claim that what is usually named "medical ethics" ought to be named "medical etiquette." In his view, Percival's code, and presumably, also, the present practice, are concerned merely with the conduct of physicians towards each other, and their purpose is to promote "the dignity and pecuniary advancement" of the individual physician and of the profession as a whole. In other words, they are trade union rules designed to secure material prosperity for the profession. Guides to etiquette they may be, but "ethics" is concerned with "professional morality" and with "the interests of humanity as a whole," and not with the small beer of "professional courtesy." The misapplication of the terms, it is argued, has unhappy consequences, for by it regulations which are based essentially on selfish interests appear to the practitioner to be informed by the noblest and most altruistic motives. Something may doubtless be said on the verbal issue between "ethics" and "etiquette," but here we have no hesitation in maintaining that all professional rules and customs must in the end justify themselves by the sanction of the public interest, and we believe that this sanction is not wanting.

Professor Leake, as a layman and a philosopher, contemplates the medical practitioner as drawn in one direction by the temptations of his own pocket, and in the opposite direction by the welfare of the patient, and almost inevitably deciding for the former, seeing that "true idealism is quite impossible in existing conditions." This, of course, is to reason *a priori*. A certain propensity of human nature

is assumed, and from this is deduced an inevitable consequence. The parallel argument is that, as an absolute monarch is all-powerful, he is certain to cut off the head of any subject who annoys him. Motives and decisions in life are not quite so simple as this reasoning implies. If Professor Leake will combine with his philosophical studies some experience of the practical life of the doctor, he will, we feel sure, be able to learn that the fashion in which the artist makes a livelihood is not unworthy of the art which he practises or of the large interests which he serves. To affirm that as physicians have a pecuniary interest in treating the physical ills of humanity they cannot sincerely desire to see mankind in perfect health, is just as sound and just as misound as to argue that judges cannot desire that litigation should cease, or soldiers war, or policemen crime, or parsons impiety. It is the existing situation, not some remote development, that governs conduct, and the situation presented to the physician offers only two possibilities. The one is to take advantage of ignorance and helplessness and emotional susceptibility, and the other is to follow decent, natural human instincts and professional traditions and pride of craftsmanship. When, as we believe is almost invariable, the doctor takes the straight course, he does not boast the "nobility" of his action, or label it "idealism," or urge his "concern for the ultimate welfare of society." He has a much simpler explanation, and this he prosaically terms "playing the game." Before Professor Leake completes his larger volume he would do well to appreciate this robust and widely spread influence in the sphere of professional conduct.

### PHYSICS OF X RAYS AND RADIUM.

IN *Physics in Medical Radiology*,<sup>2</sup> by SIDNEY RUSS, L. H. CLARK, and B. D. H. WATERS, the authors have obviously attempted to produce a book dealing with the subject which can be read and understood by medical men; radiologists, and electrotherapeutists mainly, who of necessity should have at any rate a basic knowledge of that physics which is in relationship to the apparatus and the radiation they use for medical purposes, both diagnostic and therapeutic. There are now three universities—Cambridge, Edinburgh, and Liverpool—in which there is an organized post-graduate course of instruction in radiology and electrotherapeutics. In each of these the physics allied to the main subjects of the course is taught by university physicists, and this book should prove of great use, both to the teachers and the students—the teachers inasmuch as it deals with and indicates quite clearly that part of physics which is required; the students because, if they are well up in the material of this work, they will have that knowledge of the subject which is not only necessary for examination purposes, but also for use later on in carrying out radiological medical work on a scientific basis. Knowledge of this subject is of the greatest importance, especially in the treatment of disease by deep x rays or radium. In short, without technical and detailed knowledge of the physics of x rays and radium it is neither safe nor satisfactory to carry out such treatment, and this applies both to the operator and the patient.

In reading this book it is very evident that the authors have endeavoured to place themselves in the position of their anticipated readers. Physics is not an easy subject for the ordinary medical man, and especially so after he is qualified; the material of many books is so very technical that it is difficult to follow. No errors have been made in this respect; indeed, almost throughout the book is both easily read and easily understood, and we have nothing but praise for the manner in which each division of the subject is set forth. In its main construction there are some seventeen chapters, an appendix on the X-Ray and Radium Protection Committee's third revised (1917) report, and an appendix dealing with a hospital radium service, whilst a list of reference books and an index bring it to completion. The book is well printed on good paper, and the numerous illustrations, diagrams, and tables contribute greatly to the easy elucidation of the text. A certain

<sup>1</sup> *Percival's Medical Ethics*. Edited by Chauncey D. Leake. Baltimore: The Williams and Wilkins Company; London: Baillière, Tindall and Cox, 1927. (Post 8vo, pp. xiv + 251; 11 plates. 12s. 6d. net.)

<sup>2</sup> *Physics in Medical Radiology*. By Sidney Russ, D.Sc., L. H. Clark, Ph.D., and B. D. H. Waters, M.Sc. London: Chapman and Hall, Ltd. 1928. (Demy 8vo, pp. xii + 234; 72 figures. 12s. 6d. net.)

amount of mathematics has been found to be essential, but in this respect the authors have been very kind, and although mathematics as applied to physics is generally somewhat difficult to grasp, at any rate as regards the ordinary medical man, the mathematics of Professor Russ and his co-authors is comparatively easy and understandable. When all is so good it is difficult to single out anything as especially worthy of mention, but there are two excellent chapters—one on radio-active emanation and active deposits, and the other on dosage in radium therapy, illustrated with some useful tables and diagrams. In addition there is a chapter on photography, light, and x rays which is full of interesting material.

While the backbone of the work is the physics of x rays and radium, other subjects are not neglected. At the beginning there are chapters on current electricity, the electrical conductivity of gases, electro-magnetic waves, and so on. At the end there are chapters dealing with electric motors, high-tension generators, high frequency, diathermy, and other currents. In all, the volume comprises 234 pages, with about 72 figures and 25 tables. It can confidently be recommended to anyone interested in the subject, and it should be invaluable to those working for one or another of the diplomas in medical radiology and electrotherapeutics.

#### EXPERIMENTAL EMBRYOLOGY.

THE distinguished professor of Columbia University, THOMAS HUNT MORGAN, in his monumental work, *Experimental Embryology*,<sup>2</sup> indicates the various phases which have ranged from the mechanical conceptions of Roux, through the colloid chemistry aspirations of Loeb, to the accurate experimental work of Spemann. The history of experimental embryology during the last thirty years is depressing to British readers, for no experimental zoologist has emerged in this country to follow in the steps of the giant morphologists of the Victorian age; and since the publication of the classical *Unsere Körperform und das Physiologische Problem Ihrer Entstehung* of W. His in 1874 no book of outstanding merit has appeared in the English tongue. Recently de Beer at Oxford has published *An Introduction to Experimental Embryology*—a hopeful sign.

Professor Morgan has written a scholarly introduction to the experimental method in this exploration of a new field. He is cautious as to the significance of statistical data, he tries to hold the balance between the morphological and the physiological approach, and he welcomes the working hypothesis as "an attempt to find an answer to some feature of a complex situation in terms of better understood relations, which, from a mechanical standpoint, means reference to accepted chemical or physical principles."

The first part of the book deals with chemotaxis, fertilization, self-fertilization, sterility, and polyspermy. This is followed by a description of the changes, both physical and chemical, in the fertilized egg, especially cleavage and the localization of the median plane. The changes in the chromosomes are carefully studied, and the genes are not accepted as in any way resembling strings of enzymes. It is suggested that the genes may be built upon a common radicle, and that these radicles may be somewhat similar or even identical in species which closely resemble one another. The description of organ formation, asymmetry, and the localization of organs in the egg before cleavage is admirably told. The development of whole and partial embryos from isolated blastomeres leads on to the problem of the fate of the various cells of the blastomere, and to a consideration of all the experimental work which has led to the production of abnormal embryos by mechanical and chemical interference. Artificial parthenogenesis is described from the days when Aristotle stated that "bees produce drones without copulation" to the days of the spectacular work of Morgan, Loeb, Wilson, and Lillie in America, of Herlant in Belgium, and Delage and Bataillon in France. Reference to Mendelian inheritance concludes the work, and it is definitely stated that the characters of embryos and of larval stages follow Mendel's laws. The progress made in the production of species hybrids is

remarkable, especially as regards cross-fertilization in different species of amphibians, sea-urchins, and bony fishes. In the case of the last, species belonging to different genera and families have been crossed—as, for example, the cod and the flounder. The hybrid always follows the mother, meets a critical age at gastrulation, and develops abnormally. In larval forms only has it been possible to find the length of time necessary for the genes of the sperm to affect the cytoplasm of the segmenting egg. That such paternal genes do influence the cross is shown by later generations from such a cross. It is to be hoped that the vistas revealed by Professor Morgan will stimulate the younger school of British zoologists. Spemann and Ross Harrison have recently lectured in London. Morgan, Conklin, and Brachet would be welcome.

#### DIAGNOSIS AND TREATMENT IN PULMONARY DISEASE.

DR. FRANK E. TYLECOTE and DR. GEORGE FLETCHER have written a short book on *Diagnosis and Treatment in Diseases of the Lungs*,<sup>4</sup> designed chiefly for the senior student and the young practitioner. Roughly speaking, one-half of the book is devoted to pneumonia and pulmonary tuberculosis, the remaining half to other diseases of the chest. The book is straightforward and simple, and calls for little comment. We would, however, draw attention to two statements, which might well be rectified in a subsequent edition. On page 141 the mortality from the different types of pneumococci is given in a statement that has been extracted from Muir and Ritchie's *Manual of Bacteriology*. Unfortunately, in the process of extraction the authors have omitted a highly important fact—namely, that the most virulent of the pneumococci is Type III. As it reads at present, it would appear that Types I and II are the most virulent; which is untrue. We would suggest either that they remedy this omission or, better still, give the actual mortality figures for the different types, which have recently been published on a large series of cases by Cecil, Baldwin, and Larsen (*Arch. f. Int. Med.*, 1927, vol. 40, p. 253). The second misleading statement is on page 193, where it is said that the greatest death rate—presumably from pulmonary tuberculosis—is during the first twenty years of adult life. The context certainly suggests that the authors mean pulmonary tuberculosis, though it is clear that they refer really to tuberculosis in all its forms. This point might well receive attention.

#### ENDOCRINOLOGY.

THE work on hormones and internal secretions<sup>5</sup> by Dr. F. LAQUER is the nineteenth volume in a series of reports on scientific progress that are being published by Messrs. Steinkopff, under the editorship of Dr. LIESEGANG. This useful series of monographs covers a wide range of scientific subjects, and each volume is intended to summarize the important work done in the subject under review since 1914. The editor remarks that the volume of modern scientific literature is such that it is impossible to study fully the original work in more than a relatively narrow field of learning. There are few subjects encumbered with a more voluminous literature than endocrinology, and the present monograph is therefore very welcome. The author summarizes the important recent work in about 100 pages, and concludes with a selected bibliography of 1,200 references. The book deals chiefly with the physiology and chemistry of the endocrine organs, but a short account of the clinical aspect also is given. Considerations of space have prevented any discussion of methods, or any full statement of conflicting evidence in disputed points. The author, however, summarizes disputable problems in a very impartial manner, and the volume forms a convenient summary of present-day knowledge and an excellent guide to recent literature in endocrinology.

## TESTS FOR COLOUR BLINDNESS.

THE type of test for colour blindness based on the method of Stilling is a well-known and exceedingly useful method of detecting the presence of this defect and eliciting its nature. The test consists in presenting to the subject an alternately irregularly arranged and confused assortment of coloured dots, among which, in another colour readily the confusion colours worked into the peculiar pattern are a series of dots arranged in the form of a letter or numeral. To a colour-blind subject whose defect includes the confusion colours worked into the peculiar pattern, the whole appears an inexplicable maze; but if the ability to see and detect the colour in question is normal the subject will be able to read the hidden letter.

There are many variants of the original tests of Stilling, two of the best known of which are those of Ishihara and Edridge-Greene. Professor HERTZ also has devised an excellent series of these "pseudo-isochromatic tables for the testing of the colour sense," which has now come out in its seventeenth edition.<sup>6</sup> If anything, these tests err on the side of being too simple. They may be well supplemented in the detection of red and green blindness by the tables of Dr. WÖLFELIN,<sup>7</sup> which are more difficult of analysis and are very well conceived.

## NOTES ON BOOKS.

THE scope of the *International Health Year-Book, 1927*, has, with its third issue,<sup>8</sup> been enlarged by the inclusion of reports from a number of sources which had not hitherto contributed, and the 800 pages of this useful work of reference now contain particulars relating to health in twenty-seven countries, including the leading member-States of the League of Nations, the United States, and the Union of Socialist Soviet Republics. In the sections devoted to the national reports there is a wealth of statistical detail relating to demography and vital statistics, supplemented by accounts, of varying length and value, of the finance, organization, and administration of public health services. The details given relate to the year 1926, and it should be noted that the earlier issues bore in their title the year with which they dealt, while the present issue bears the date of publication. Special sections are devoted to industrial hygiene in Germany, Belgium, and Great Britain, and to certain international organizations, and the concluding chapters give an account of the activities of the Health Organization of the League of Nations in 1927—this body is, of course, responsible for the publication. It may be pointed out that no particulars are given regarding Scotland or Northern Ireland. The Irish Free State supplies its own independent report, while that furnished by the Ministry of Health relates only to the area within its own jurisdiction—that is, to England and Wales. Probably the omission of any specific indication that this is the case will not mislead anyone in Great Britain, but readers in other countries unacquainted with our constitutional peculiarities may mistake the part for the whole.

The second volume of the seventh edition of the well-known textbook on bacteriology<sup>9</sup> by Professors K. B. LEHMANN of Würzburg and R. O. NEUMANN of Hamburg has been brought up to date by inclusion as far as possible of the latest literature. The work is divided into two unequal parts, the first and smaller part being devoted to general bacteriology, while the second part, which forms the bulk of the volume, is concerned with the various groups of bacteria. There are three appendices, dealing respectively with the smallest filterable viruses, the most important pathogenic protozoa, and the bacteria of definite regions and objects.

*Latin Names of Common Plants*<sup>10</sup> is an entertaining little book by Dr. F. DAWTREY DREWITT, who wrote the charming *Romance of the Apothecaries' Garden at Chelsea*. Dr. Drewitt is distressed that botanists tread the footsteps of medical men into the morasses of false quantity, instead of following the more pure-minded zoologist. Why, he asks, should cyclamen

he called "sicklymen" when cyclone have not become "sickle" and "sicklone"? If helium is rightly pronounced, why not *heliotope*? Most dictionaries give the pronunciation of *oenothera* correctly; but one *encyclopædia* gives *oenothera*. Such errors as *lycopodium* can only be compared with the medical man's pronunciation *paræsis*, instead of the equally easy *paræsis*. Dr. Drewitt admits that the use of some false quantities has become so firmly ingrained that we cannot expect alteration. Thus it is hardly likely that *crocus* will ever come to be pronounced *krōkōs*. In other cases reason may be shown why a word should not be pronounced in accordance with strict classical Latin. Dr. Drewitt quotes Sargenut on the word "gladiolus" as stating that "although Terence would have pronounced it *glādiolūs*, Quintilian, like Cicero, would have said *glādiolūs*"; and Dr. Drewitt regards the latter pronunciation as a reasonable compromise, because it is grand, rolling, and musical. Dr. Drewitt tells us that two owo most of the Latin names of plants to Dioscorides, Pliny, and Linnæus. As two of these botanists belonged to classic Rome, we might at least try to show some respect for the language in which they wrote.

*The Confessions of a Tenderfoot "Coaster"*<sup>11</sup> deals with the life of a trader on the West African coast, and may be classed among the lesser sort of travel books. Mr. HENRY sets out simply to give his own experience, and in his first ten lines states that his book will not add to anybody's knowledge of West African geology, fauna and flora, or ethnology. He has, nevertheless, produced a thoroughly readable volume, which may be of special interest to some medical men in view of its candid account of the effects of life in the tropics on the outlook and habits of Europeans.

<sup>11</sup> *The Confessions of a Tenderfoot "Coaster."* By Warren Henry. London: H. F. and G. Witherby. 1927. (Demy 8vo, pp. 280; 6 plates. 16s. net.)

## PREPARATIONS AND APPLIANCES.

## APPLIANCES FOR INFANTILE PARALYSIS.

Dr. G. McCracken (Leicester Isolation Hospital and Sanatorium) writes: The following appliances may interest those who have to deal with post-febrile cases of infantile paralysis.

*Deltoid Shelf.*

In cases of deltoid paralysis when a good faradic response has been obtained it is desirable to discard the abduction frame and to encourage movements of the deltoid without causing stretching of the muscle fibres. This can be obtained either by slinging the arm to an overhead frame or by supporting the limb on pillows. Both these methods involve keeping the patient in bed. The accompanying photograph illustrates a simple method of overcoming this difficulty. The shelf is made of poroplastic supported by a flared strip of aluminium. A shoulder strap, fixed back and front helps to keep the split in position. The shelf allows free antero-posterior movements in the horizontal plane; it is easy to make, and can be worn day and night.

*An Internal T-Strap.*

This internal T-strap is very useful in those cases in which we have to deal with a weak *tibialis anticus* and flat-foot. It is a modification of Calot's artificial *tibialis anticus*, and has the advantage that it not only relieves *anticus* of undue strain, but also supports the arch of the foot to such an extent that the child walks with the foot in an over-corrected position. Another advantage is that there is no tendency for the origin of the artificial muscle to slip down the limb. It consists of a strap of soft leather stitched to the outer side of the sole of the boot. This passes across the instep, is continued up the front of the leg, and buckled to the outer side of a band fixed below the head of the tibia by an outside iron from the heel of the boot. This internal strap supports a firm leather insole and is adjustable.

Both appliances are simple in construction and have proved most satisfactory in practice.

I am indebted to Dr. H. Stanley Banks, medical superintendent, Leicester Isolation Hospital, for the accompanying photograph, and his permission to publish these notes.

<sup>6</sup> *Stillings' method*. Tafeln zur Prüfung des Farbensinns. Professor Dr. E. Hertel. Siebzehnte Auflage. (Cr. 8vo, pp. 2; 14 plates. M.18.)

## POST-OPERATIVE TETANUS.

REPORT TO THE SCOTTISH BOARD OF HEALTH.

THE occurrence of a series of cases of post-operative tetanus in an institution led the Scottish Board of Health to request Dr. T. J. Mackie, Irvine Professor of Bacteriology in the University of Edinburgh, to investigate the matter. Since this infection has in the past been associated with catgut, Professor Mackie was asked at the same time to report also upon the effectiveness of the means employed for sterilization of catgut in its manufacture, storage, and use in hospital; the dangers attendant on its use in surgery; and the best available means for effective sterilization during manufacture, storage, and use in hospital. The report of this inquiry has now been published by the Stationery Office, at the very low price of 1s., in order that the important conclusions reached may be available for all surgeons and medical schools throughout the world. Professor Mackie, who was assisted in the inquiry by Dr. G. S. McLachlan, lecturer in bacteriology at Edinburgh University, believes that the investigation has not only elicited data of the utmost significance in regard to the whole problem of post-operative tetanus, but has also led to an extended study of preventive methods which deserves the most careful attention. The Scottish Board of Health expresses its full agreement with Professor Mackie's assessment of the importance of the facts now published.

## INCIDENCE AND ETIOLOGY.

The report opens with references to the literature showing that post-operative tetanus has been commonly attributed to catgut, though cases have occurred in which this material was not employed, and auto-infection was incriminated. The valuable suggestion is proffered that information should be collected systematically regarding the incidence of post-operative tetanus in all the general hospitals in Great Britain, since at present it is probable that many cases are not published. It is well known that *B. tetani* occurs as a commensal organism in the alimentary canal of various herbivorous animals, including the sheep, from the intestines of which surgical catgut is prepared. Other anaerobic sporing bacilli capable of producing serious wound infections are also found in the intestine, and the conditions prevailing in abattoirs from which the raw material for making catgut is obtained render contamination very easy. Subsequent sterilization of the catgut is a particularly difficult matter owing to the resistant powers of the tetanus spores. Post-operative infections by other sporing bacilli have also been reported, and this emphasizes the difficulty of adequate sterilization of the catgut. During the period in which the cases of post-operative tetanus occurred at the institution in question, the surgical catgut employed was supplied almost entirely from one source, mostly in the form of "dry strings," which had already undergone some measure of sterilization but were subjected to further bactericidal treatment before being used in operations. During the investigation this supply of catgut was stopped.

## Clinical Details.

Of the eleven cases of post-operative infection in the institution considered in the report one had occurred so long ago as 1923; in no instance was it possible to trace any connexion between the catgut used for the various patients, and the operations in the more recent cases were separated by intervals of twelve, nineteen, nine, and seventeen days. The highly significant fact was elicited that in gynaecological repair operations a considerable amount of catgut remained embedded in the tissues; it was estimated by one surgeon that approximately 69 inches might be so left after a repair operation for complete prolapse of the uterus. Moreover, in such operations it is a common practice to employ the thicker gauges of gut. Though *B. tetani* was not always demonstrated, there was little doubt about the diagnosis in any of the patients in view of the clinical and pathological data.

In the whole series there were nine cases of definite tetanus,

one of gas gangrene, and one of a sporing anaerobe infection with muscular spasms. In five out of the six tetanus cases the infection followed gynaecological repair procedures; the operation in the sixth case was oophorectomy combined with appendicectomy. The remaining three cases were associated respectively with a cholecystectomy, a nephrectomy, and a gastro-enterostomy. In the gas gangrene case an exostosis of the leg had been removed, and the infection with the sporing anaerobe was the sequel of excision of the cervical glands. Ten different surgeons were concerned, and six operating theatres. All the patients died except one, in whom tetanus supervened after a repair operation for a retracted uterus and a deficient perineum. The incubation period in this case was fourteen days, as contrasted with incubation periods of seven to twelve days in the fatal cases. The time of death after the onset of tetanus ranged from a few hours to five days. In the tetanus cases the wound was apparently healthy in two cases, and septic in another two; there was gangrene of the tissues in three other cases, blood extravasation in one, and no evidence about the wound was obtainable in the remaining case. *B. tetani* was demonstrated in two cases, tetanus-like organisms were found in two, and other sporing organisms in two cases. No organisms were isolated in one case, and in two others no bacteriological examination was performed. Negative bacteriological findings are admittedly of little significance in the diagnosis of tetanus cases. Five of the nine cases occurred after operations in one theatre which was on the ground floor and close to a main corridor. Constructional work was proceeding in its neighbourhood, but no further evidence was obtained indicating that these local conditions were concerned in the infection. The possibility of auto-infection was carefully considered, but this explanation had to be dismissed in the absence of data.

## CONTAMINATED CATGUT AND TETANUS.

Professor Mackie mentions that the preparation of the catgut included: (1) twelve hours' immersion in a watery solution of mercury biniodide; (2) heating at 160° C. for one hour in oil; (3) heating in anhydrous spirit in a Jellett's sterilizer in boiling water for one and a half hours; (4) storage in an antiseptic fluid containing a mixture of mercury biniodide and other antiseptics. The technique of the last three procedures was carefully reviewed, and no evidence was obtained of any carelessness or inexactitude. The dry catgut strings were tested, and were found to contain sporing anaerobic bacilli of the group to which *B. tetani* belongs; these (*B. tetani* and *B. mesentericus*) were used for testing purposes, and it quickly became obvious that exposure for twelve hours to the watery solution of mercury biniodide could have but little effect. A certain proportion of the spores of *B. mesentericus* survived heating in oil at 160°, and the margin of the destruction of *B. tetani* was very narrow. The ineffectiveness in this respect of heating in a Jellett's sterilizer was completely demonstrated, and spores remained viable finally after storage in the mixed antiseptic solution. In only one procedure was *B. tetani* destroyed. Intermittent sterilization in heated oil was tried but was found to ruin the catgut, as did also streaming steam sterilization and exposure in an autoclave to superheated steam. The efficiency of very many chemical bactericides was tested; hydrogen peroxide and iodine water proved to be the best, but the action of some reputed bactericides was found to be surprisingly feeble. Details are given of these tests and the results. It was concluded finally that catgut "ribbons" could best be sterilized by immersion in hydrogen peroxide (10 vols.) for twelve hours, the catgut strings spun from these ribbons being further exposed for fourteen days in iodine water. These procedures, which do not damage the catgut, can be employed in factories; it is suggested that, subsequently, the strands should be passed through two changes of spirit to remove the iodine, and be stored in 50-75 per cent. alcohol containing 0.1-0.2 per cent. iodine. It is added that these processes should be controlled in operation by bacteriological examinations.

## COMMENT.

The great importance of this inquiry is obvious. Confirmation is necessary and the experiments require to be repeated under factory conditions; Professor Mackie's data are set out so fully that this should be relatively easy. An interesting point is that the investigation arose out of a definite group of clinical cases, and it is possible that further

<sup>1</sup> An Inquiry into Post-operative Tetanus. A Report to the Scottish Board of Health. By T. J. Mackie, M.D., D.P.H. H.M. Stationery Office. 1s. net.

discoveries in other directions await a similar line of reasoning and research to be adopted following clinical observations. Professor Mackie describes the gradual progress of the reasoning concerned in the inquiry in a manner suggestive of the tracking down of a criminal, and there is much valuable evidence placed on record for use in other connexions. In his conclusions he calls attention to the fact that there is at present no control by any health authority over the manufacture of catgut such as exists over certain biological products. He believes that such a control is required, and he thinks that manufacturers would welcome aid in standardizing their methods of preparation and safeguarding their products. He proposes also a collective investigation of the general incidence of operative tetanus, of infections by other spore-bearing anaerobes, and of the various etiological factors concerned in these infections. He adds that the official notification and investigation of future cases would supply information of great value as regards prophylaxis. The possibility of auto-infection and the part played by carriers of *B. tetani* are also commended for study. For the present, at any rate, a case seems to have been made out for the standardization of the methods of preparing and sterilizing catgut; there can be little doubt that this will receive due consideration.

### BIRTHDAY HONOURS.

The honours list issued on the occasion of His Majesty's birthday included the names of the following members of the medical profession:

#### Companion of Honour.

Professor JOHN SCOTT HALDANE, M.D., D.Sc., F.R.S., Director of the Mining Research Laboratory of Birmingham University, for scientific work in connexion with industrial disease.

#### K.C.M.G.

Lieut.-Colonel Sir WILLIAM THOMAS PROUT, Kt., C.M.G., O.B.E., Senior Medical Adviser to the Colonial Office.

#### K.C.V.O.

JOHN MARNOCH, C.V.O., Regius Professor of Surgery, University of Aberdeen.

#### K.B.E. (Military).

Major-General WALTER HOLLAND OGILVIE, C.B., C.M.G., K.H.P., I.M.S.; Director of Medical Services, Army Headquarters, India.

#### Knights Bachelor.

Dr. JAMES ATKINSON HOSKER, J.P., Chairman of the Bournemouth Conservative Association, for political and public services in Bournemouth.

Dr. THOMAS WATTS, M.P. for Withington Division of Manchester, for political and public services.

Lieut.-Colonel HENRY SIMPSON NEWLAND, C.B.E., D.S.O., Australian Army Medical Corps, Surgeon to the Adelaide Hospital.

#### C.B. (Military).

Major-General HAROLD BEN FAWCUS, C.M.G., D.S.O., K.H.P., Deputy Director-General, Army Medical Services, War Office.  
Colonel HAROLD BOULTON, C.B.E., I.M.S., V.H.S., Assistant Director of Medical Services, Deccan District, India.

#### C.M.G.

Dr. JOHN HOPE REFORM, lately Director of Medical and Sanitary Services, Uganda Protectorate.

#### C.I.E.

Lieut.-Colonel ERNEST WILLIAM CHARLES BRADFIELD, O.B.E., I.M.S., Professor of Surgery, Medical College, and Superintendent, General Hospital, Madras.

Lieut.-Colonel LEWIS COOK, I.M.S., Civil Surgeon, Bhagalpur, Bihar and Orissa.

Lieut.-Colonel GEORGE DENNE FRANKLIN, O.B.E., I.M.S., late Chief Medical Officer, Delhi.

Lieut.-Colonel JOHN CUNNINGHAM, I.M.S., Director, Pasteur Institute, Kasauli.

Dr. HUGH GORDON ROBERTS, Welsh Mission at Shillong, Assam.

#### C.V.O.

Dr. ALFRED BAKEWELL HOWITT (dated April 21st, 1923).

#### C.B.E. (Military).

Colonel HOWARD ENSOR, C.B., C.M.G., D.S.O., late R.A.M.C., Deputy Director of Medical Services, North China Command.  
Surgeon Captain JAMES HERBERT FERGUSON, R.N.

#### C.B.E. (Civil).

Major JOHN HARRY HENN, O.B.E., R.A.M.C.(ret.), Director of Medical Services, Ministry of Pensions.  
Lieut.-Colonel JOHN E. STRATHAIRN, O.B.E., Warden of the Hospital of the Order of St. John of Jerusalem in Palestine.

#### O.B.E. (Military).

Major JAMES HEDDERLEITHWAITE MARTIN FÉDÉRICIER, R.A.M.C.  
Lieut.-Colonel HUMPHREY FRANCIS HUMPHREYS, M.C., 143rd Field Ambulance, R.A.M.C., T.A.

Major GORDON WILSON, M.C., R.A.M.C.  
Surgeon Commander BRYAN PICKERING PICK, R.N.

#### O.B.E. (Civil).

Surgeon Commander WALTER KEMPSON HOPKINS, R.N.(ret.), Medical Officer, Board of Customs and Excise.

Professor ALBERT VICTOR BERNARD, M.B.E., Medical Officer of Health, Mülten.

MANGALDAS VIJAYKHANDAS MEHTA, Medical Practitioner, Bombay.  
Dr. GEORGE RANDELL FOOTNER, Director of the Omdurman Civil Hospital.

Rai Bahadur Dr. KISHORI LAL CHAUDHRI, M.B.E., Assistant Director of Public Health, United Provinces.

Dr. JAMES GONFREY LYON BROWN for services in connexion with the Emergency Volunteer Corps at Hankow.

#### M.B.E. (Military).

First-class Assistant Surgeon EDWARD HENRY GILLSON, Indian Medical Department.

#### M.B.E. (Civil).

Dr. GEORGE MACLEAN, Sleeping Sickness Officer, Medical and Sanitary Department, Tanganyika Territory.

Mrs. MARTHA ISABEL GARVIE, Senior Lady Medical Officer, Egyptian Ministry of Education.

Dr. JAMES FREDERICK CORSON, Assistant Bacteriologist, Medical and Sanitary Department, Tanganyika Territory.

Dr. RUTH YOUNG, Personal Assistant to the Chief Medical Officer, Women's Medical Service, and Secretary of the Funds under the Presidency of Her Excellency the Lady Irwin.

#### Honorary M.B.E. (Civil).

Dr. YESHUA SHAMI, Medical Officer, Department of Health, Palestine.

#### Kaiser-i-Hind Medal (First Class).

Dr. CHRISTIAN FREDERICK FRIMODT-MÖLLER, Medical Superintendent, Union Mission Tuberculosis Sanatorium, Madanappalle, Chittoor District, Madras.

Dr. ANNIE CAROLINE SMITH, in charge of the Zenana Hospital of the Church of Scotland Mission, Gujrat.

Dr. ROBERT JOHNSTON ASHTON, Kachwa, Mirzapur District, United Provinces.

#### Imperial Service Order—Companion.

Khan Bahadur ANJUM BAKHSH, Assistant Residency Surgeon, Personal Assistant to the Administrative Medical Officer in Central India and Superintendent, Central India Agency Jail, Indore.

### ROYAL MEDICAL BENEVOLENT FUND.

THE total sum which has been voted this year in grants to medical men, their widows, or orphans who have appealed for help amounts to approximately £4,744 as against £3,502 during the corresponding period of last year—an increase of £1,242. These figures definitely prove there is a greater demand being made on the Fund this year than ever before. But subscriptions and donations do not show an equivalent increase over the same period. To meet an increase of £1,242 in grants, subscriptions have only increased by £500.

An urgent appeal is made for subscriptions and donations, which should be sent as soon as possible to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, London, W.1.

The following are notes on a few of the cases helped at the last meeting.

Dr. X, aged 63, had to give up practice three and a half years ago owing to cataract on both eyes. He is too blind to see patients and can do no work of any kind. During these three and a half years he has had to live and maintain himself, his wife, and two young children on his small capital, which is now exhausted. An emergency grant of £15 was made, and a further sum voted of £40. Assistance is being sought from other charitable funds.

Dr. Y, aged 73. Old age and increasing deafness have prevented this applicant from continuing in the profession, and for some time he has been forced to live on capital. Other family troubles have made heavy financial claims upon the applicant, so that all his life savings are now exhausted and he has had to apply for the old age pension of £26 a year. Voted £40.

Widow, aged 55, of M.R.C.S. Owing to ill health the applicant's husband sold his country practice ten years before he died, and during this time up to his death he and his wife had to live on capital. At his death the widow found there was nothing left, his life policies had been mortgaged years before, there were debts, and there was no money to pay for the funeral. The widow had to sell furniture and other private possessions in order to pay. Her son can only contribute 10s. a week. Voted £25.

Daughter, aged 59, of M.D. The applicant has been teaching as a governess for forty-two years; now at her present age she cannot get regular employment. Her savings bring in £50 a year. She was not able to save more as she had to help keep her invalid mother for the last twelve years of her life. Voted £25.

# British Medical Journal.

SATURDAY, JUNE 9TH, 1928.

## PUERPERAL SEPSIS.

EARLY in 1925 the Council of the British Medical Association, recognizing the urgency of the problem of childbed infection, set up a special committee to consider "the causation of puerperal morbidity and mortality, and the administrative action, if any, that should be taken in connexion with the matter." An interim report was issued within twelve months,<sup>1</sup> and the Committee's final report has been published recently in our columns as an appendix to the Annual Report of Council.<sup>2</sup> Towards the close of its deliberations the Committee held a conference with representatives of official bodies directly interested in one or other of the subjects coming within its reference, and a number of practical suggestions then put forward have been embodied in the recommendations with which the final report closes. It will be generally agreed, we think, that the Committee has done an important service by drawing attention to the many factors as yet unexplained in the incidence of puerperal sepsis, and by indicating those in which further experimental research appears to be most needed. The intricacy of the problem, and the zeal with which it is now being attacked by widely different routes, find expression in the three papers with which our present issue opens.

It will be observed that the Committee set up by the British Medical Association accepts the common classification of possible sources of childbed infection into exogenous and endogenous. Dr. James Young, on the other hand, so far from entering the lists on behalf of either an exogenous or an endogenous origin, dismisses both as of secondary importance in maintaining the sepsis rate, and assigns the chief place to trauma from intervention. He considers that the question where the microbe comes from is overshadowed by the vital issue of trauma, that the infecting organisms may be either exogenous or endogenous, and sometimes of a type that causes disease only when settling in devitalized tissues. To some it may appear that Dr. Young has laid undue emphasis on injury as the determining factor in the risk of sepsis, though there will be general agreement as to the important part it plays. Infection of the uterine cavity is an outstanding feature of most cases of puerperal sepsis, and to its causation all internal manipulations, whether accompanied by tissue injury or not, must contribute, for the vulva, cervix, and vagina cannot be made germ-free. All hospital records show increase of morbidity incidence with intervention, and the morbidity rate is greater the higher up the genital tract the manipulation extends, the greatest risk of sepsis being reached with such intrauterine operations as manual removal of the placenta when the fingers work in the bare uterine cavity.

Though Dr. Young adds a proviso that it must not be assumed that the main responsibility is thereby placed on the medical attendant, he does not carry the matter further than by throwing out a suggestion of a possible change in the fitness of the women of to-day for child-bearing, and hazarding a view that skeletal defects may have increased owing to the greater care of infant life and consequent larger survival of those who suffered from rickets in childhood. A reduction in infantile deaths entails also a corresponding reduction in the far larger number of infantile casualties that do not end in death. The incidence of rickets of all degrees of severity will rise or fall in correspondence with the place of rickets in the mortality rate. The most obvious change in the child-bearing women of to-day as compared with their predecessors of a few generations back is that they—and first of all those of the more educated and well-to-do classes—have learnt of the relief of pain and shortening of their travail that anaesthesia and the obstetric forceps can bring. Their medical attendant is chosen largely with this relief in view, and he must steer a difficult course between the complete fulfilment of their desires by frequent interference with natural function or be thrown over for someone more compliant. Pressure from his patients, from their distracted husbands (like the one lately pictured in *Punch*), and other relatives, together with the strain of his other work and all the circumstances in which family practice is conducted, have made it almost impossible for him to resist and survive. We would rather put the question thus. If the women of all classes in the country were prepared to have their confinements conducted as those attended by the midwives of the Queen's Institute or in the hospitals whose figures Dr. Young contrasts with the national mortality rate, would the difference between the rates remain at its present level?

Dr. Young mentions the need for educating the public, but he does not go so far as to suggest that the medical profession should teach their patients that a price must be paid for the relief in labour for which they crave—a price part of which at least is represented at the moment by the failure to reduce the maternal mortality. His plea for concentration on the effort to secure natural delivery is timely, for the primary objective throughout Medicine—the maintenance of normal function—has to some extent been overshadowed in the practice of midwifery by the attempt to attain the secondary objective of relieving pain and shortening the time of trial for the woman in labour. Team work between doctor and midwife, as advocated in the report of the British Medical Association's Committee (para. 34) and urged by Dr. Young, has the great advantage of offering a better chance of lessening interference and the trauma on which he lays such stress. Though much may be done to secure normal function in labour by a whole-hearted co-operation between doctors and midwives, the demand of the women for relief and, in the present state of our knowledge, the price of relief given on "humane" grounds will still appear in the national balance sheet. A lowering of the cost might be made were more known (as the report says) of "the degree and kind of immunity of the pregnant woman."

Dr. Burt-White's preliminary report of an effort to

<sup>1</sup> Supplement to the British Medical Journal, January 9th, 1926.

<sup>2</sup> Ibid., April 28th, 1928.

unravel the capricious incidence of puerperal sepsis from the side of resistance to the streptococcal toxin records the puerperal morbidity in a hundred women divided into two groups according to their reaction to the injection of scarlatinal toxin. So far as it has gone, his investigation shows that women who react to the scarlatinal toxin are more liable to develop puerperal sepsis than those who do not react. Once knowledge of this kind has been definitely established, and it has become possible to pick out those in whom resistance to infection is low, and still more when it is known how this low resistance can be raised, the risks of artificial aid in delivery will be greatly lessened. Dr. Remington Hobbs's paper falls into a different category, both because it is concerned with the curative rather than the preventive side of puerperal infection, and because Dr. Hobbs has widened his consideration to include types not discussed in the other two papers.

We are glad to note that the Minister of Health, in pursuance of a policy designed by his department for grappling with this problem as a whole, has just appointed a Departmental Committee, wholly medical in composition, whose terms of reference are "to advise upon the application to maternal mortality and morbidity of the medical and surgical knowledge at present available, and to inquire into the needs and direction of further research work." The names of this committee are given at page 998. It will be seen that all branches of medical work in any way concerned in the matter are represented, and that two general practitioners—one from a country town and the other from the East End of London—have accepted membership. The personnel should therefore command the confidence of the profession and the public, and we may feel assured that full advantage will be taken of the work already carried out by the British Medical Association on the lines of the Departmental Committee's reference.

#### GORDON OF ABERDEEN.

It seems appropriate to call to mind this week an eighteenth century Scottish physician, Alexander Gordon, whose *Treatise of the Epidemic Puerperal Fever in Aberdeen* was published in 1765. A sympathetic account of this pioneer has lately appeared from the pen of Dr. Herbert Thoms of New Haven, Connecticut.<sup>1</sup> Gordon was born at Strachan, a small parish situated to the south-west of Aberdeen, in 1752. Little is known of his early life, but he took his degree of M.A. at Marischal College, Aberdeen, and subsequently began the study of medicine, first at Aberdeen Infirmary and later at Edinburgh. He joined the navy as a surgeon's mate in 1780, and two years later obtained the rank of surgeon. In 1785 he retired on half pay, and came to London, where he became a resident pupil at the Lying-in Hospital, Store Street, and attended lectures on midwifery by Thomas Denham and Osborn. He then became a pupil under Thymie, and attended lectures on surgery and dissections at the Westminster Hospital under Justamond. After this training Gordon returned to Aberdeen and obtained his M.D., and was shortly afterwards appointed physician to the dispensary, where he gained a reputation for conspicuous success in the treatment of acute diseases, especially fevers. In addition to the appointment to the infirmary, to which in the course of the next nine years

12,925 cases were admitted, he was occupied by a large private practice, in which he devoted himself particularly to obstetrics, and gave an annual course of lectures to the medical students. Four years before his death he was called back by the Admiralty to active duty in the navy, where he fell ill with pulmonary tuberculosis and was invalided home. His death took place on October 19th, 1799, when he was 47 years of age. Dr. Thoms cordially agrees with A. W. W. Lea, who maintained that Gordon was to be credited with having first clearly demonstrated the infectious nature of puerperal fever. Oliver Wendell Holmes was so much impressed with Gordon's treatise that in his essay he quoted the following paragraph in capital letters: "By observation I plainly perceived the channel by which it was propagated, and I arrived at that certainty in the matter that I could venture to foretell what women would be affected with the disease, upon learning by what midwife they were to be delivered or by what nurse they were to be attended during their lying-in, and almost in every instance my prediction was verified." With extraordinary honesty Gordon continues: "It is a disagreeable declaration for me to mention that I myself was the means of carrying the infection to a great number of women." In another important passage Gordon shows the analogy between puerperal fever and erysipelas, in both of which the infectious matter is readily absorbed by the lymphatics in the vicinity of the wound. Gordon not only demonstrated the infectiousness of puerperal fever, but had a definite idea of the pathology of the condition, whereas his contemporaries Hulme and Lako pronounced the omentum to be the seat of the disease. Gordon by his dissections showed that puerperal fever was a disease which principally affected the peritoneum and the ovaries. Lastly, he laid down the following rules for prophylaxis: "The patient's apparel and bedclothes ought either to be burnt or thoroughly purified, and the nurse and physicians who had attended patients affected with puerperal fever ought carefully to wash themselves and get their apparel properly fumigated before it is put on again."

#### INTERNATIONAL HEALTH SERVICES.

No one outstanding topic emerged at the twelfth session of the Health Committee of the League of Nations, which was held at Geneva from April 30th to May 5th, but several matters of considerable interest came under review, and the proceedings gave an admirable illustration of the development of health measures in the international sphere. It was reported, for example, that the Epidemiological Intelligence Bureau at Singapore is now in regular telegraphic communication with 140 ports; the weekly bulletin based on the information so gained is circulated by wireless, and an increasing number of stations transmit it, so that it is more widely available for ships at sea. Efforts are being made to secure the collection, through the bureau, of information regarding quarantine stations and their value, and it has also been suggested that the bureau should secure the most detailed statistics possible on the seasonal prevalence of cholera and plague within its sphere. In various directions special inquiries are in progress dealing with particular diseases. Expert subcommittees, at the instance of the Cancer Commission, are undertaking studies of occupational cancer and the radiological treatment of cancer; the investigation into the incidence of small-pox in Europe is to be extended to North America and the Dutch East Indies, and an inquiry into infant mortality is proceeding in Europe and South America. The report of the Sleeping Sickness Commission is to be considered by an international conference composed of representatives of governments interested; proposals are put forward for securing continuous study of the disease, for the co-opera-

<sup>1</sup> Amer. Journ. Obstet. and Gynecol., February, 1928

tion of workers in various countries, and for the systematic collection of information. Measures are now being taken to prepare a scheme for an international inquiry into leprosy. The work of the Malaria Commission is proceeding, and, as in previous years, special courses have been arranged on malaria. This enumeration does not by any means exhaust the tale of the Health Committee's activities in this sphere, but it will suffice to give an indication of one aspect of its work. The establishment of standards for certain therapeutic substances is another of its functions: the unit for insulin adopted in 1925 has been accepted universally, and the standard for pituitary extract has also proved satisfactory; work on international standards for antitetanic and antidyenteric serums is now practically completed, and good progress has been made with antiphtheritic serum. Two collective interchanges of public health personnel, arranged by the Health Committee, will take place this year. Members of the health services of sixteen other countries will visit Italy, studying first the central administration in Rome, and then dispersing in groups to other centres to devote themselves to special subjects. The second interchange is of a new type, and will be attended by medical officers and sanitary engineers concerned with health administration in rural districts; they will be drawn from countries in Europe and South America and from Russia, and will visit selected areas in Europe. Two examples occur in the report of the committee's proceedings of the way in which the League organization has been able to assist particular countries. The medical director of the committee is to co-operate with the authorities in Greece in preparing a scheme for a campaign against tuberculosis in Greek towns, while an offer of assistance in dealing with the urgent health problems caused by the recent disastrous earthquake in Bulgaria has been accepted by the Government of that country. It is probably difficult for most of us, accustomed as we are to thinking in terms of relatively small unified areas or of single highly specialized services, to gain an adequate conception of the work carried on by the League agencies in connexion with health. Their activities are widely varied, the areas concerned are often remote, and the problems which engage attention are usually not of first importance in this country, so that the whole system is liable to impress itself but vaguely upon our consciousness. Perhaps, however, the Health Organization and the Health Committee of the League will seem more worthy of notice when we reflect that they in their sphere have achieved, it would seem, a greater degree of international unity and co-operation than the parent body has yet been able to reach in the political sphere through the efforts of the politicians and the diplomats. Representatives of the United States have played a considerable part in the work of the Health Committee, while officials from Soviet Russia will participate in the interchange visits arranged for this year. The two "big exceptions" to membership of the League itself are therefore in contact with the Health Organization.

#### MEDICAL EXAMINATION OF CIVILIAN AVIATORS.

A second edition of *The Medical Examination of Civilian Aviators*<sup>1</sup> has now been published by the Air Ministry after a lapse of nearly eight years. When the first edition was reviewed in the *Journal* of May 1st, 1920 (p. 608), our notice concluded with the opinion that the pamphlet might serve as a model when the international tests were decided upon by the medical representatives of the International Commission for Air Navigation. A summary of the international medical requirements, in so far as they affect civilian aviators, forms the first section of the revised issue, and the standard exacted does not vary much from

that previously laid down in this country; the specific methods of examination and the minimal conditions of the tests are left for the present to the decision of each country until the International Commission shall arrange otherwise. As in former years, the British system lays greater emphasis upon the prescribed general clinical examination and upon the importance of good family and personal history than upon "efficiency" tests, which are given due recognition, but are quite definitely subordinated to the general scrutiny, embodying a medical and surgical examination and investigation of the eyes, ears, nose, and throat. In connexion with the personal history, guidance is given regarding certain disabilities which should be regarded as indicating unsuitability for air work. In other directions also the relation between the various mental and physical qualities, and the characteristics demanded of pilots, are fully explained, so that an examiner may readily appreciate the precise importance of his work. Diagrams illustrate the apparatus employed in certain of the tests. The notes on "assessment" state that, apart from the elimination of those who fail to satisfy the requirements in respect of sight and hearing, or who show signs of disabling organic disease, the assessor's main duty is to ascertain that the accepted candidate possesses stamina and nervous stability compatible with the safe landing of aircraft from any altitude, even in the case of prolonged and difficult flight. As an aid to decisions in this respect various tests of the cardio-vascular, respiratory, and neuro-muscular systems have been devised, and a "physical efficiency index" has been formulated. The standards for these tests have been set by comparing the performance of pilots chosen as fit and successful with that of pilots suffering from known defects impairing their flying capacity. Reference must be made to the importance attached to vision. It is common knowledge that most flying accidents occur in landing, and it is remarked that lack of true ocular muscle balance has been proved to be the most common cause of error in judgement in bringing an aircraft to the landing ground. Apart from its value to those engaged in performing one of the most exacting medical examinations yet devised, and rightly so, this little manual will interest medical practitioners generally. It reveals, for example, something of the demands which the exercise of his art makes upon the pilot's mind and body. It is also possible that some of the tests described might be applied usefully elsewhere. In a modified form they would no doubt give a very clear indication of the capacity of motor drivers and others engaged in occupations which require a considerable degree of nervous stability and co-ordinated muscular action. The anonymous authors are to be congratulated on producing a pamphlet which, in the space of fifty pages, not only admirably fulfils its express purpose, but also embodies much interesting matter of general application.

#### THE LEISHMAN MEMORIAL AT MILLBANK.

On June 2nd, two years exactly after his death, a memorial tablet to Lieut.-General Sir William B. Leishman, K.C.B., F.R.S., was unveiled in the chapel of the Queen Alexandra Military Hospital, Millbank, and another in the pathological laboratory of the Royal Army Medical College. The unveiling of the former took place during a brief dedicatory service conducted by the Chaplain-General to the Forces (the Rev. Dr. A. C. E. Jarvis, C.M.G.). The ceremony of unveiling was performed by Lieut.-General Sir Matthew Fell, Sir William Leishman's successor as Director-General of the Army Medical Service, who explained that the tablet was part of the memorial subscribed for by the officers, past and present, non-commissioned officers, and men of the R.A.M.C., and members of the military nursing services. The major part of the memorial consisted, he said, of a medal which had been struck and prizes which would be

<sup>1</sup> H.M. Stationery Office, 1928. Price 1s.

competed for by officers and men of the corps. Sir William Leishman served the army for thirty-eight years, and won great honours, especially in the field of research in pathology, but it was affection for the man as well as admiration for his work which had inspired this memorial. He was known to his officers of the service as no other officer was known. Not only was he their teacher, but their companion and friend. After the service those present walked across to the Royal Army Medical College, where Major-General David Harvey unveiled over the entrance to the pathological laboratory the second tablet. He said that while the memorial in the chapel was intended to commemorate Sir William Leishman as a great Director-General, the memorial in the laboratory recalled him as a teacher, an eminent man of science, a research worker, and a discoverer of world-wide renown. Although the memorial had been erected at Millbank, it was only right to say that much of Leishman's work was carried out elsewhere. The original discovery of the parasite of kala-azar was made in the old laboratories of the Army Medical School at Netley; there also Leishman prepared the stain which bore his name, and it was there he was associated with Almroth Wright and David Semple in work on the typhoid vaccine—work which was subsequently to develop to such a remarkable extent in the army, to be the means of saving thousands of lives of British soldiers in India and elsewhere, and to be adopted and adapted by practically every nation in the world. On the transfer of the school to London Leishman became professor of pathology and put in very strenuous work. General Harvey described his teaching carried on in that very room, and his gradual attainment to the position of a national figure in the field of research, so that there was hardly a piece of organized medical research with which he was not connected; but he added that Leishman was not a scientist absorbed in his pursuit as to be oblivious of the claims of family and friends. He was a devoted husband and father, and nothing would have pleased him more than the high degrees in science recently obtained by two of his daughters and the academic career of his son. "Tablets will crumble in the course of time, but the name and fame of William Leishman will be passed on," said General Harvey in conclusion, "from generation to generation." The tablet in the college records the fact that Leishman carried out his researches on typhoid, kala-azar, relapsing fever, and other diseases in that place, where he taught from 1907 to 1913. The tablet in the chapel recites his many military, medical, and academic distinctions. The ceremonies were attended by Lady Leishman and other members of the family, and by a large number of past and serving officers, while among others present were Sir John Rose Bradford (President of the Royal College of Physicians), Dr. Andrew Balfour, Sir Almroth Wright, Sir David Semple, Air Vice-Marshal David Munro, and many more who came into close touch with Sir William Leishman's life and work. The British Medical Association was represented by Dr. Alfred Cox, Medical Secretary.

#### THE HARVEY TRICENTENARY IN PARIS.

In the week following the celebration in London of the three hundredth anniversary of the publication of Harvey's great work a special meeting of the Académie de Médecine for the same object was held in Paris, when this country was represented by Sir John Rose Bradford, President of the Royal College of Physicians, Professor Barcroft, who occupies the chair of physiology at Cambridge, and the British Ambassador. Addresses, of which the full text will be found in the official organ of the Académie,<sup>1</sup> were delivered by the President, Dr. Béchère, and Professors Chauffard, Gley, and Achard. Dr. Béchère, after welcoming the

British delegates, emphasized the attention which Harvey's discovery had excited from the first in France, not only in the medical, but also in the philosophical and literary world. While the doctrine of the circulation met with the opposition of Riolan and Guy Patin, it received the warm support of Descartes, who gave a detailed description of it in his celebrated *Discours de la Méthode* and his *Traité de l'Homme*, while Beileau and Molière held up to ridicule the opponents of the new discovery. Professor Chauffard expressed appreciation of his reception in London as representative of the Académie de Médecine, and repeated the address which he had delivered at the Royal College of Physicians.<sup>2</sup> Professor Gley, who reminded his audience of the commemoration by the Académie de Médecine of Edward Jenner in 1823 and of Thomas Sydenham in the following year, discussed the significance and development of Harvey's work, which was foreshadowed by Servetus, Colombo, and Cesalpinus, and brought to completion by Pecquet, Malpighi, and Leenwenhoek in the seventeenth century, Lamure and Bertin in the eighteenth, and Claude Bernard and Marey in the following century. The proceedings closed with a short address from the general secretary, Professor Achard—in which he expressed his best wishes for the progress of British science and the prosperity of the Royal College of Physicians—and the presentation to its President of a Latin address, in which a eulogy of Harvey was combined with an expression of goodwill to the College.

#### DAWSON WILLIAMS MEMORIAL FUND.

We publish this week at page 994 a further list of contributors to the memorial to Sir Dawson Williams, Editor of the *British Medical Journal* from 1898 to 1928, who died on February 27th last. The first list appeared in our issue of March 17th (p. 461). We are asked to call attention to the fact that the fund will be closed on Saturday next, June 16th, and that any further contributions should therefore be sent at once to the Honorary Treasurer. The Organizing Committee is now engaged in preparing recommendations, and all subscribers will shortly be summoned to attend a general meeting to consider them. Cheques should be made payable to Sir StClair Thomson, and sent to 64, Wimpole Street, London, W.1, the envelopes being marked "Dawson Williams Memorial."

The summer dinner of the Australian and New Zealand Medical Association in England will be held at the Trocadero Restaurant, Piccadilly, on Friday, June 15th, at 8 p.m. This will be preceded by a general meeting at 7.30 o'clock, which all visitors and members are requested to attend, to elect office-bearers for the forthcoming year. Sir Anthony Bowlby, Bt., K.C.B., K.C.M.G., K.C.V.O., is the official guest of the Association. All medical visitors from Australia and New Zealand are invited to be present. The honorary secretaries are Mr. E. T. C. Milligan, F.R.C.S., and Mr. Philip J. Jory, F.R.C.S., 66, Harley Street, W.1 (Langham 2828).

The annual report of the radium department of the North Canterbury Hospital Board, Christchurch, New Zealand, for the year ending March 31st, 1928, records that the total number of radium applications during the year was 498. On several occasions radium was taken out of the hospital for the treatment of patients in private hospitals or in their homes. Since the opening of the radium department in November, 1924, 234 patients suffering from rodent cancer have been treated, of whom 203 are at present free from any signs of this disease, and in the non-malignant uterine haemorrhage of middle age radium proved of special value. Ultra-violet ray treatment was found to be very beneficial in certain cases of disease of the nervous system.

<sup>2</sup> *British Medical Journal*, May 19th, p. 868.

## Nova et Vetera.

### THE ARRIVAL OF THE JEWS IN ENGLAND.

Is a communication to the *British Medical Journal*, September 26th, 1925, I gave some examples of early charters witnessed by medical men, and commented on the rarity of medical witnesses in general to ancient deeds. Since that date I have consulted the chartularies of numerous English houses, and, although I have met with a certain number of medical witnesses, I see no reason to modify the attitude I took up—namely, that it is uncommon to find a doctor acting as a witness. In two documents, taken from the Brinkburn chartulary, a still rarer phenomenon is exemplified, a medical man being a principal party to early deeds.

The Brinkburn chartulary was published by the Surtees Society in 1892 (vol. 90). In it is the record of an agreement between the Prior and Convent and Henry the physician of Newcastle-on-Tyne concerning a house in Newcastle. The gist of this deed is as follows.

Know all men present and to come that this is the agreement made between William Prior of Brinkburn and the convent of the same place and Henry the Physician of Newcastle-on-Tyne, viz., that the aforesaid prior and convent have let to fee firm to the aforesaid Henry a house with appertinances in Westgate near the castle ditch which they hold by gift of Alexander of Gloucester. To have and to hold to the aforesaid Henry and his heirs or assigns, Jews and men of religion excepted [exceptis Judeis et viris religiosi] of the prior and convent of Brinkburn for ever freely and quietly. Paying therefor yearly to the prior and convent two shillings at Pentecost for all services and dues and besides the rent due to our Lord the King. And be it known that if the aforesaid Henry, and his heirs or assigns are behindhand in payment of the aforesaid rent on the dates due, the aforesaid land with buildings [literally principals] which shall have been erected on it shall be taken into the hands of the prior and convent, until the said Henry and his heirs or his assigns shall have satisfied the said prior and convent. And the said Henry and his heirs or his assigns shall keep the aforesaid land and buildings in good repair at his own proper cost. And the aforesaid prior and convent will warrant the said land with appertinances to the said Henry and his heirs or his assigns for ever. In witness of which we have fixed the seal of our chapter to this chirograph script in the year of our Lord 1219, on the day of the nativity of St. John the Baptist. These being witnesses, Dominus Peter Scott, Master William the son of the Dean and others.

A second deed is No. 216 in the same chartulary: it is a grant of a rent from the house mentioned in the first deed to John, son of Geoffrey Waleman of Haliwell, the marriage gift to the daughter, Ysota, of the grantor. The gist of it is as follows.

To all who shall see or hear this writing, Master Henry the Physician of Newcastle-on-Tyne, greeting. Know that I have given conceded and by this my present charter have confirmed to John son of Geoffrey Waleman of Haliwell in free marriage with my daughter Ysota an annual rent of 2/ of that house in Newcastle near the castle ditch of the same town which formerly I held of the Prior and Convent of Brinkburn received yearly at Pentecost of Roger son of Guy or his heirs or assigns. To have and to hold to the said John and his heirs of the said Ysota my daughter. . . . If Ysota should happen to have no issue I will for me and my heirs that the aforesaid annual rent of 2/ shall remain to the prior and convent of Brinkburn for the health of my soul and of Alice my wife and all my ancestors in free and perpetual alms for ever. And that my gift may remain firm and stable I have affixed my seal to this writing. These being witnesses, Dominus Eustace Delaval, Dominus Henry his brother and others.

The clause in the first of these deeds excluding Jews calls attention to an interesting liberty accorded to certain towns in England—the privilege that no Jew might dwell or stay in that town. Newcastle's privilege is contained in a charter of Henry III. Madox, in his history of the Exchequer (1711), gives a copy of the King's writ to the Sheriff. This I have translated as follows:

The King to the Sheriff of Northumberland greeting. Know that we have conceded and by our charter have confirmed to our true men of Newcastle-on-Tyne and their heirs that they may have this liberty, viz., that no Jew in our time or in that of our heirs may remain or make any residence in the same town. As is more fully contained in the King's charter which he has caused to be made to them. And it is commanded to the said sheriff that he may publish the said charter through his whole county and allow them to have this liberty. Witness the King at Kennington 4th, July 18 Henry 3rd.

Madox states that another town to have this anti-Jewish privilege was Derby, which was one of the famous five boroughs of the Danes, the others being Lincoln, Leicester, Nottingham, and Stamford. I do not know whether any

of these towns were granted the same liberty. It might have been thought that the document transcribed by Madox was forged, as the contents of it are distinctly unusual, but the first of Dr. Henry's deeds shows that the privilege was a real one. What the unfortunate inhabitant of Newcastle did if he wished to raise a loan I cannot tell.

The first entry of the Jews into this realm is an interesting point; doubtless some will be ready to assert that our first Jewish resident was Joseph of Arimathea, whose thorn bloomed at Glastonbury, but this would seem to be a myth. A friend of mine has suggested to me that they may have accompanied the Phoenicians to Cornwall in their visits to this country in search of tin; I have no proof that this is the case, and I cannot help thinking that if they did visit England with the Phoenicians, they made no settlement in Cornwall. Everyone knows that the Jews were banished by Edward I and that their return to settle in this land was one of the many things we owe to Oliver Cromwell; was it not stated the other day that he was willing to let them have St. Paul's Cathedral for a synagogue? A superficial search of Kemble's *Codex* has not yielded any evidence of a Jewish section of the population in early Anglo-Saxon times. In no Anglo-Saxon charter have I seen the name of anyone who could be looked upon as a Jew, either in the body of the deed or among the witnesses. I do not find that Oswald, the saintly Bishop of Worcester, granted any leases for three lives to any persons with Jewish names, but it is frequent to find in that clause which was inserted to make the deed more binding the pious hope expressed that if anyone violates this gift may he burn for ever with Korah, Dathan, and Abiram!

Towards the end of the Anglo-Saxon era we have definite evidence that there were Jews in England. The laws of Edward the Confessor declare the King to be the protector of all Jews. They counted as strangers; they could not be in hundred or tithing as free men; and the protection of strangers being one of the royal prerogatives, they belonged to the Crown, as did also a portion of their wergild (fine for murder), and their property in case of death. So far as my researches have gone, the Confessor's laws give us the first definite evidence of the Jews in England.

The Conqueror brought Jews from Rouen to London. William of Malmesbury, speaking of the doings of William Rufus, says: "Judæi qui Londoniæ habitabant, quos pater e Rothomago illic traxerant."

I do not think that there is any evidence in Domesday Book to show that there were many Jews in England in 1086. London, of course, is not included in the survey; but, on the other hand, the Jews figure largely on all the pipe rolls to which I have access. When the celebrated usurer, Aaron of Lincoln, died in 1186, his goods and debts were taken into the King's hands, and it is of interest to find that they do not appear on the pipe rolls till five years later, so that it took a considerable time to wind up an estate in those early times. The Angevin Kings kept a very tight hold on the Jews. They were allowed to settle in the larger towns of the realm; they had the King's peace—at a price—and were more often than not fleeced by him as they were in the habit of fleecing his subjects. One may say that from the beginning of the reign of Henry II till 1290 the Jews afforded the most convenient means of raising money. Stubbs, in the *Constitutional History of England*, says that "they were exempted from the general taxation of the country to be tallaged by themselves; for the Jews, like the forests, were the special property of the King. . . . Henry II in 1187 exacted a fourth part of the chattels of the Jews; John in 1210 took 60,000 marks by way of ransom; Henry III in 1230 took a third of their chattels; and in 1255 he assigned the whole body of the Jews to Earl Richard as security for a loan." In France St. Louis expelled them from the country in 1252. In England Simon de Montfort persecuted them, and Edward I in 1290 banished them from the kingdom.

The fact that the Jews are with us to-day in such numbers has always seemed to me a strong argument against the rapid decline and fall of the British Empire.

# Dawson Williams Memorial Fund.

## SECOND LIST OF SUBSCRIBERS.

SINCE the first list of contributors to the Dawson Williams Memorial Fund was published in these columns, on March 17th, subscriptions have been received from those whose names appear in the list printed below. Those who may have overlooked the matter are invited to send their subscription before Saturday, June 16th, when the list must be definitely closed. The Organizing Committee will then draw up recommendations for the disposal of the fund, and all subscribers will shortly afterwards be requested to attend a meeting to consider them. The honorary treasurer is Sir StClair Thomson, F.R.C.S., 64, Wimpole Street, W.1.

Abercrombie, Dr. Peter  
Acland, Dr. Theodore Dyke  
Aitken, Dr. C. J. H. (Kilnhurst)  
Auld, Dr. A. Gunn  
Batt, Dr. Bernard (Bury St. Edmunds)  
Bazin, Dr. A. T. (Montreal)  
Blenkinsop, Major-General Sir Alfred (Frensham)  
Bond, C. J., F.R.C.S. (Leicester)

*Incorrectly entered in Previous List.*

Watson-Williams, Eric, F.R.C.S., should read Dr. Patrick Watson-Williams (Clifton).

## THE VOLUNTARY HOSPITALS COMMISSION.

### FINAL REPORT: TERMINATION OF THE INQUIRY.

THE final report of the Voluntary Hospitals Commission,<sup>1</sup> dealing with the requirements in respect of voluntary hospital accommodation of England and Wales, has been presented to the Minister of Health. In April, 1924, it will be recalled, Mr. Neville Chamberlain's predecessor, Mr. John Wheatley, requested the then existing Commission to institute an inquiry into this subject. A short interim report was presented in July, 1925, and a summary of it appeared in the JOURNAL of August 15th, 1925 (p. 305). The document now under review is equally brief, occupying little more than five pages, with an appendix of statistical matter less than two pages in length. The work of the Commission has now, with the concurrence of the Minister, been terminated, and the final report represents little more than a summary of the present position as it compares with that disclosed in the earlier survey.

It will be convenient to recall at this point that the Commission in its interim report recommended that an Exchequer grant, or a series of grants, amounting to £2,000,000 should be made to help to meet new capital expenditure for additional voluntary hospital accommodation, and that the Minister of Health intimated his inability to proceed with the proposal. Meanwhile, the final report states, more progress has been made than was considered probable. The report, apart from surveying the hospitals position, deals mainly with finance. It concludes that there is no ground for apprehension regarding the ability of the hospitals to maintain such additional beds as may be provided, directs attention to the growing importance of systems of mass contributions from the industrial classes, and suggests that this must be regarded as the only quarter likely to yield any substantial growth of income. The Commission's proposal for dealing with a difficulty often referred to in these columns is that some form of compulsory insurance for motorists should be introduced to relieve the voluntary hospitals of the burden thrown upon them by the growing frequency of road accidents. Details from the report are given below.

<sup>1</sup> London: H.M. Stationery Office, or through any bookseller, 1928.

### The Task of the Commission.

The Commission was instructed to inquire into and report upon "the extent of the additional voluntary hospital accommodation required in England and Wales and the best means of providing and maintaining it." The final report bears the signatures of the following members: The Earl of Onslow (chairman); Sir Robert Bolam, M.D.; Sir John Rose Bradford, K.C.M.G., M.D., P.R.C.P.; Dr. R. C. Buist; Lord Clwyd; Mr. H. Wade Deacon; Dr. W. E. Elliot, M.P.; Sir George Makins, G.C.M.G.; F.R.C.S.; Mr. D. O. Malcolm; Dr. F. N. Kay Menzies; Sir E. Cooper Perry, M.D. Lord Linnlithgow, owing to his absence as Chairman of the Royal Commission on Agriculture in India, was not able to take part in any of the Commission's deliberations on the final report, and for this reason his name is not appended. The death of Sir Robert Hudson deprived the members of a colleague whose assistance had been of great value.

The opening section of the report recalls the conclusions presented in the interim report, referred to above, and the reception its recommendations met with from the Minister of Health, stating the position in the following terms:

Early in 1926 you informed us that you had, with great reluctance, come to the conclusion that the financial situation of the country was such as to make it impracticable at that stage to proceed with the proposals for a grant from public funds towards the cost of new construction on the lines of our recommendations. We received your decision with regret, though we were bound to recognize the force of the considerations which led you to it. You have now intimated to us that our main task having been accomplished you do not feel justified in asking us any longer to continue our work as a Commission. While we cannot but regret that it has been impossible to implement proposals to which we devoted much time and thought, we desire to take this opportunity of expressing our appreciation of the confidence which you and your predecessors have reposed in us.

### Recent Growth in Hospital Accommodation.

A survey of the present position is then given based on a comparison of the figures for June, 1924, and for the end of 1926. The expansion in available accommodation has been, it is disclosed, more rapid and more widespread than the Commission anticipated when preparing the 1925 report. The figures prove that during the period of two and a half years the hospitals have shown marked activity in the matter of extensions, and during the latter part of

that period the rate of expansion has considerably exceeded the provision required to keep pace with the growth of the population, with the result that the arrears of the war period are being gradually but appreciably reduced.

One allowance must, of course, be made for the growth of population, and the report points out that the excess of bed accommodation available at the end of December, 1926, over the figures for June, 1924, must not be taken as representing a net gain. At the time of the 1924 survey the ratio of beds to population was 1.33 per 1,000. This ratio, however, was based upon a figure of accommodation which the Commission believed was 10,000 beds short of what was reasonably necessary. If this deficiency had not existed the ratio of beds to population would have been 1.6 per 1,000, and this represents the rate at which the hospitals must expand to keep pace with the growth of population. The increase in population in the thirty months between the date of the 1924 survey and the end of 1926 is estimated at approximately 638,000. On the basis of 1.6 beds per 1,000 it was necessary, therefore, for the hospitals to provide 1,020 beds to meet this increase.

The returns received by the Commission from local voluntary hospital committees, including King Edward's Fund for London, showed that in this period 3,829 beds were actually provided, or 2,809 more than the number required to meet the growth of population. This represents an average reduction of arrears at the rate of 1,124 beds per annum. This the Commission regards as less than is ideally satisfactory, but as considerably better than there was reason to anticipate, and it is stated that, taking the amount of money becoming available as the test, the position appears still more hopeful. It is pointed out that in London the receipts for building purposes amounted in 1925 to £735,000, and in 1926 to £479,000, as compared with an average of £308,000 for the three years 1922-24, and it is further stated that, although London is in some respects in a specially favourable position, and figures for the provinces are not available, there is ground for believing that the amounts appropriated for building purposes have substantially increased, and that a further improvement in the rate of progress may reasonably be expected.

#### *The Problem of Maintenance.*

In its previous report the Commission expressed the opinion that there is no reason for apprehension as to the ability of the hospitals to provide for the additional beds. It was found that while in 1925 a substantially larger number of beds had to be maintained than in the previous year, the excess of income over expenditure amounted to as much as £734,000, or over £100,000 more than in 1924. Owing chiefly to the industrial conditions prevailing in 1926 the financial position in that year was less favourable than in 1925, but the Commission is confident that with the return to more normal conditions the position will again improve. The success with which the hospitals met this crisis, it is suggested, indicates the extent to which the financial structure of the system has recovered from the strain of the war period.

It is important, however, that no one should lose sight of the fact that the views reported above refer to the general position, and the Commission evidently desires to make it clear that the outlook is by no means entirely satisfactory. Referring to this point the report states:

Although in the aggregate a deficit has not been experienced since 1922, there are still areas in which the income of the hospitals is insufficient to meet the expenditure, and in which for this reason it has not yet been possible to undertake extension on an adequate scale. These areas comprise some of the most important hospital centres in the country. Indeed, it is the large general hospitals with medical schools attached in which the costs of maintenance are higher than in other hospitals, which find the greatest difficulty in collecting the funds necessary for carrying on the ordinary work of the hospital to the fullest extent. Failure to solve the problems of maintenance and extension in those areas cannot fail eventually to react to the prejudice of the voluntary system.

#### *Schemes for Mass Contributions.*

Dealing with the nature of hospital income, the Commission has found in certain areas where financial recovery was most marked some system of mass contributions, and the members have concluded that the only quarter whence any substantial increase in income

may be expected in the future is from the industrial classes. The report points out that legacies are a problematical element, and that the proportion of income from large subscriptions is unlikely to increase, while they feel that the interest of the middle-class subscribers has been remarkably well maintained having regard to the benefits they enjoy from the hospitals. The conviction is expressed that the future of the voluntary system depends in a large measure on its success in securing in one form or another the continued support of the small contributor.

In this connexion the Commission emphasizes the need for recognizing that the framing of any scheme of mass contributions calls for the exercise of great care to avoid the acceptance by the hospital of liabilities which cannot be discharged, or the creation in the minds of contributors of expectations which may not be fulfilled. The effect of such scheme upon the government of the hospital and the relations of the medical staff must also, it is stated, be taken into consideration. The report proceeds:

It is hoped that those local voluntary hospital committees which have not turned their attention to this problem will make a real effort, in conjunction with hospitals, to establish, under adequate safeguards, such schemes wherever circumstances permit. We have not in the past pressed this conclusion upon local committees because we realized the manifest risks and difficulties which the system entails. But the experience of recent years has convinced us that this is the main source of new income, and while the dangers are real we do not believe them to be insuperable.

Reference is made to the fact that many of the local voluntary committees instituted on the recommendation of the Cave Committee are still in existence, and the Commission places on record its indebtedness to those committees for their assistance in its work.

#### *The Hospitals and Motor Accidents.*

Attention is finally called to the effect of the increasing frequency of motor accidents upon hospital finance. No detailed investigation has been made, but the Commission agrees that this is placing a heavy burden on many institutions, and expresses its opinion on the matter in the following terms:

This charge ought not to fall upon funds derived largely from the generosity of the charitable, whose gifts are intended for the relief of persons who have not the means to provide institutional treatment at their own cost. While the possession of a motor is very far from being evidence of affluence, those who can afford to maintain a car would suffer no hardship if by some system of compulsory insurance they were required to pay the premium, probably comparatively small, which would be needed to cover the treatment of their own injuries as well as those which may be caused to others. The incidence of this burden is very unequally distributed, and it falls with special severity on the hospitals which are situated on or near those new roads whose excellence from an engineering point of view affords a seemingly irresistible temptation to excessive speed.

It is recognized that the proposal would involve legislation, and may excite controversy, but the Commission can see no other way of imposing the charge on those by whom in equity it should be borne.

#### *Hospital Accommodation Statistics.*

An appendix to the report gives details, by counties, comparing the position in England and Wales in respect of voluntary hospital accommodation at the end of 1926 with the position in June, 1924. The figures are given for bed accommodation at each date; the number of additional beds stated to be required in 1924; the increase in the period mentioned; and the number of additional beds in course of provision at the end of 1926. For the country as a whole revised figures, prepared since the issue of the previous report, show that there were available in mid-1924 50,679 beds, while 13,252 beds were stated to be required. By the end of 1926 the number available had increased by 3,829 to 54,503, and 2,964 beds were in course of provision, so that the deficit on estimated requirements had been reduced considerably. However, as the report indicates, allowance must be made for the increase in the population. It should be noted that in its earlier report the Commission took the view that some economy could be secured in the number of beds required by local co-ordination and other means, and concluded that the then existing requirements could be met by the addition of 10,000 beds.

In London the revised figure for the available accommodation in 1924 was 13,880 beds, and it was estimated that 2,093 additional beds were required; accommodation had been increased by 597 beds up to the end of 1926, and 1,130 more were in course of provision, so that substantial progress had been made.

The situation outside London was less satisfactory; between June, 1924, and the end of 1926, 3,232 additional beds had been provided, and at the end of the period 1,834 beds were in course of provision, while at the beginning of the period additional requirements were stated to be 11,164 beds. Wales and Monmouth were stated at the first survey to need 1,102 beds; in the thirty months following 427 were provided, but at the end of the period only 43 more beds were in course of provision. Some time has elapsed since the collection of these figures, but they serve to reveal the disparity existing in the extent to which the hospitals in various parts of the country have been able to increase their accommodation.

## THE MEDICAL INSURANCE AGENCY.

### TWENTY-FIRST ANNIVERSARY DINNER.

THE twenty-first anniversary of the establishment of the Medical Insurance Agency was celebrated by a dinner at the Hotel Victoria, London, on May 30th. Sir HUMPHRY ROLLESTON, chairman of the Committee of Management, presided, supported among others by the Chairman of Council of the British Medical Association (Dr. H. B. Brackenbury), the Chairman of the Representative Body (Dr. C. O. Hawthorne), and the Treasurer (Mr. Bishop Harman). The company included also many well-known men in the world of assurance and of medical charity.

The health of the Medical Insurance Agency was proposed by Mr. ARTHUR DICKEY BESANT (Past President, Institute of Actuaries, and General Manager of the Clerical, Medical, and General Life Assurance Society), who said that its genesis might be traced to the special committee set up by the British Medical Association at the time of the passing of the Workmen's Compensation Act for the purpose of assisting the profession in the problems arising out of that legislation. The work of the Agency at first was more or less of a limited character, but in addition to workmen's compensation questions it dealt with the insurance of motor-cars, although the age of the motor car had then scarcely begun. Incidentally, it was not always realized that medical men were pioneers in putting the motor car to practical daily use. Presently the great insurance offices came into the picture. Some insurance men were invited by the organization now known as the Agency to give advice on the technical questions involved. Insurance men, said the speaker, were naturally modest persons, but they did recognize a golden opportunity when it came their way. On the one side were thousands of medical men, all immersed in busy practice, with neither the time nor the inclination to deal with complicated insurance matters for themselves, and on the other was the British Medical Association, anxious to take up the burden, for which purpose it had already appointed a committee. Little wonder that the committee of management and the insurance offices naturally gravitated towards each other. The war put a temporary stop to the development, but as soon as peace came the committee of management was reorganized and strengthened, and the work went forward with leaps and bounds. Since the Medical Insurance Agency started it had arranged life and endowment insurances totalling to one and a half million pounds, and that was by no means the whole of its business. In motor car insurance and in household, accident, and other insurances the figures were also impressive. That was a wonderful testimony to what had been effected in twenty-one years. The keynote of the Agency in 1907 it was resolved that the whole of the surplus funds should be devoted to the benefit of the insured member who had fallen on evil days, and though this policy was widened eventually, the charitable motive was continued and found fuller expression, and in twenty-one years, he believed, over £18,000 had been contributed to medical charities.

Sir ROBERT BOLAM, in responding, referred to some of the pioneers, notably Radcliffe Crocker, the chairman of the first committee. Only lately one of the men most prominent in the early days of the enterprise—Dr. J. A. Macdonald—had been gathered to his rest. Another whose passing they mourned was Sir Dawson Williams. Mr. Besant's figures were not quite up to date. During the last ten hours money had been voted which brought the contributions to charities during the twenty-one years up to more than £20,000. (Applause.) Epsom College had been asked to accept a contribution to found a scholarship with which the name of their revered friend Dawson Williams should be associated. He would suggest to Mr. Besant that the reason why the Medical Insurance Agency had to change its policy with regard to the disposal of its surplus funds was self-evident to any member of an insurance corporation—namely, that the medical man who insured would not come upon poverty or distress, and therefore the Agency

was left to distribute its surplus among those who lacked such provision. The Agency valued very highly the cordial co-operation of the various insurance corporations which had aided in the work. The Agency held itself free to give the best possible advice to the profession as to the investments its members should make in insurance on the merits of the case, and was not interested in the commission if it could find a better proposition where no commission was offered.

Mr. L. FERRIS-SCOTT, Secretary of the Agency, in a further response to the toast, compared the Agency to a stool with four legs—namely, the companies through which it worked, the medical profession whose interests it served, the charities which it helped, and, finally, the staff of the Agency, who had helped loyally to build it up. He himself came in at the third septennium of the Agency's existence, after the foundations had been well laid. But in the early years it was necessary to feel one's way, and those concerned, notably Mr. P. N. Adamthwaite, the agent, had set themselves to learn about insurance from the very beginning. The companies were always most anxious to help the Agency; it was greatly helped by the British Medical Association, and by the *British Medical Journal* and the *Lancet*. Very few concerns could possibly have been started or carried on under such favourable auspices, though possibly few had to work in such difficult soil.

Dr. R. LANGDON-DOWN proposed the health of the guests, many of whom he mentioned by name. The Hon. EVELYN HUBBARD, in responding, said that the company over which he had had the honour to preside since the first year of the present century (the *Guardian*) was the first to come into alliance with the Medical Agency. The success of the combination had resulted from the remarkable good feeling manifested on all sides, and also from the skill and ingenuity with which insurance experts had been able to devise special policies and terms of contract to meet the difficult and varying cases. He was a little doubtful about the practice of paying commissions by the companies, though when confined to moderate limits, as in this country, it was almost free from objection, and in this instance the use which was made of the commissions—namely, their devotion to charity—deprived the critic of his ground completely. Sir CHARLES SYMONDS (Treasurer, Royal Medical Benevolent Fund), who also responded, said that the first contribution from the Agency to the Fund was made in 1910: it was not large, but it was sweetened by the promise that it would be repeated, and in the course of eighteen years no less than £10,000 had gone from the Agency to that Fund alone, to the inestimable benefit of members of the profession, their widows, and families who had fallen on evil days. Not only so, but the Fund had gained greatly because it had had Sir Robert Bolam, Dr. Hawthorne, Mr. Bishop Harman, and Mr. Ferris-Scott in its councils.

Sir SQUIRE SPRIGGE, in a very amusing speech, proposed the health of the chairman, and Sir HUMPHRY ROLLESTON, in responding, said that he thought anyone should be proud of his association with an agency of this kind, which had been of enormous benefit in the direction of providence to the medical profession as a whole, by putting medical men in touch with the best possible insurance companies; and, in the direction of charitable assistance, to those members of the profession and their families who had been less prudent or less fortunate.

## Scotland.

### Retirement of Sir Leslie Mackenzie.

SIR W. LESLIE MACKENZIE retired last week from the post of medical member of the Scottish Board of Health. The Board has recorded in the minutes its appreciation of the services which he has rendered as a medical officer of health, as a medical inspector on the Local Government Board for Scotland, and, at a later period, as a member of the staff of its medical board and of the body which took over its duties as the Scottish Board of Health. The minute continues that for the last quarter of a century Sir Leslie Mackenzie has exercised a profound influence upon public health administration in Scotland, while schemes which owed their beginning to his advocacy or design have been carried out with beneficial results, examples being the measures taken for the treatment of tuberculosis, for the medical inspection of school children, and for the care and supervision of mothers and young children. On May 31st Sir Leslie Mackenzie was the recipient of a presentation consisting of a handsome piece of silver plate and a gold pencil from the Board. Sir Leslie has accepted an invitation to go to Kentucky to inaugurate a new hospital which has been formed for

service of the mountainous areas in the Alleghany Mountains of that state, modelled on schemes in the Highlands and Islands of Scotland, in the formation of which he took a prominent part. Lady Mackenzie has also been invited to take part in the American visit on account of the social work with which she had been concerned in Scotland, and both sailed for America from Southampton on June 5th. The choice of an official of the Scottish Board of Health to perform this ceremony may be regarded as a tribute to the Scottish health administration.

#### Harveian Festival at Edinburgh.

The 141st Harveian festival was held in the Royal College of Physicians at Edinburgh on June 1st; this event has taken place annually for nearly a century and a half, since the founding of a club to commemorate William Harvey on the instigation of Andrew Duncan in the year 1787. On the present occasion Dr. Robert Thin, president of the Edinburgh Harveian Society, occupied the chair and delivered an address upon Dr. Archibald Pitcairne and his connexions with Harvey. He reminded his hearers that Pitcairne, in the latter part of the seventeenth century, had been distinguished as a poet, literary man, and medical scientist, as well as a Jacobite politician. In relation to Harvey, Pitcairne attracted great attention because he was the first to demonstrate by a mathematical proof, similar to that used by Harvey himself, that the blood must pass from arteries to veins through capillaries; he had made this demonstration even before Malpighi, with the help of the newly discovered microscope, had seen the corpuscles passing through these minute vessels. As a result largely of this research, Pitcairne was called to the professorship of medicine at Leyden. After his return from Leyden he was the real founder of the Edinburgh Medical School upon which others had raised the superstructure. After the address the members of the Harveian Society and their friends sat down to a banquet in the Hall of the College of Physicians. According to time-honoured custom one of the courses of the dinner consisted of *Cœur de Boeuf Harveian*. After the toast of the "Imperial Forces" had been proposed by Mr. David Lees, and acknowledged by Dr. C. E. Douglas, "The Immortal Memory" was proposed by the President, and the minutes of the preceding year's meeting were read by Mr. J. W. Dowden. "The Health of the Guests" was proposed by Professor Edwin Bramwell, and a reply was made by the Very Rev. the Dean of the Thistle, after which "The Health of the President" was proposed by Dr. Robert A. Fleming, President of the Royal College of Physicians. The tercentenary proceedings were closed with the usual toast of "*Floreat res Medica*."

#### Visit of the Lord High Commissioner to Edinburgh Hospitals.

The Lord High Commissioner to the General Assembly of the Church of Scotland, and Lady Stair paid a visit, on May 23rd, to the Royal Infirmary of Edinburgh, where they were received by members of the board of management and of the staff, and visited two wards in the medical and surgical houses. The Earl of Stair afterwards distributed the prizes gained by nurses in competitive examinations. He remarked that this training school for nurses had been founded in December, 1872, and that prizes had been given so far back as 1875. The recent institution of State examinations for admission to the State Register of Nurses had emphasized the importance of systematic study in the nurses' curriculum. The need was now recognized for more highly educated nurses to occupy administrative posts and to take appointments as teachers, public health workers, and in other departments of social activity. For this reason the stimulus given to study on the part of nurses by the award of prizes was to be highly commended. The present course of study in the Infirmary embraced the subjects required by the State syllabus, and was a preparation for the State examinations. An "Affleck" medal, founded for annual distribution by the late Sir James Affleck, was given every year to the nurse, who distinguished herself most in examinations, in work in the wards, and in general efficiency and conduct throughout

her whole training. At the Deaconess Hospital, which they visited on May 29th, the Lord High Commissioner and Lady Stair were received by Lord Sands and other members of the hospital board and staff. A tour was made of the various wards, Lady Stair and members of her suite speaking to each patient in turn. She visited also the newly installed x-ray department, where she had her hand photographed while the process was explained. Lord Sands, in welcoming the visitors, stated that the past year had been a successful one, for in addition to carrying out a large amount of medical work in the wards and in the out-patient department, the hospital had been able to balance its accounts on the credit side, and had been able to install a new x-ray apparatus by the gift of a private donor. The prizes were presented to the successful nurses by Lady Stair. Visits were also paid during the general assembly, to the Sick Children's Hospital, the Royal Maternity Hospital, and the Royal Blind Asylum.

#### Cameron Prize.

The Cameron Prize of the University of Edinburgh has been awarded this year to Professor C. Levaditi of the Pasteur Institute, and he will deliver the following two lectures at 4 p.m. in the Medical School: June 15th, Chemotherapy of bismuth; June 18th, Neurotropic ectodermoses. The Cameron Prize was founded in 1878 by the late Dr. A. R. Cameron of Richmond, New South Wales. It is a prize awarded, usually annually, to a person who has recently made any highly important and valuable addition to practical therapeutics. The list of prize-winners commences with the names of Pasteur and Lister, and includes such names as Behring, Horsley, Finsen, and Ehrlich; the last recipient was Dr. Banting.

#### Edinburgh Foot Clinic.

The new premises established by the Edinburgh Foot Clinic, which has been in existence for some four years, were opened by the Countess of Stair at 81, Newington Road, Edinburgh, on May 30th. They include two operating theatres as well as ample waiting-room and other accommodation. The demand for the services of this clinic is indicated by the fact that on the days when consultations are held, from eighty to one hundred patients are treated, while there is a waiting list for treatment of over 1,600 persons. Lady Stair, when declaring the premises open, suggested that the clinic should give advice to young women against going to their work at which they would have to stand most of the day wearing thin high-heeled shoes. She hoped that the clinic had a great and useful future before it. At the annual meeting, held prior to the opening, the chair was taken by Mr. C. W. Cathcart, F.R.C.S. The annual report showed that in the past year the number of treatments had been 6,915, as compared with 5,335 in the previous year. There had been an excess of income over expenditure of £43. Subscriptions and donations amounted to £166, showing that the clinic was still dependent on the generosity of subscribers for the continuance of its work. A special appeal to meet the expense of alteration and equipment in taking over the new premises was issued and the sum of £682 was received, but the building and equipment account still showed an excess of expenditure over income of £600. Professor John Fraser, F.R.C.S., in moving the adoption of the report, said that minor disabilities of the feet formed one of those collective maladies which received little sympathy and sometimes scant attention. The human foot was a very perfect piece of mechanism when it was considered how many miles it was capable of travelling and how many hours it had to bear the weight of the body. Napoleon, in his famous aphorism, that an army marched on its stomach, was guilty of an exaggeration, for the soldier on active service knew the truth in regard to the feet. The men who had been in the retreat from Mons could tell them that their clearest memory was neither of bodily fatigue, hunger, nor of merciless shell fire, but of the ceaseless ache of bruised feet. The foot parade of war time was one of the details which made for the efficiency of the soldier, and the same thing applied to the worker in

these days of competitive trade efficiency. They owed a debt of gratitude to the experts who were giving their services gratuitously to this deserving object.

#### Glasgow Western Infirmary.

At a meeting of the Board of Managers of the Glasgow Western Infirmary held on May 29th, the following new appointments were made: R. Barelay Ness, M.A., M.B., F.R.F.P.S., honorary consulting surgeon; George Allison Allan, M.D., F.R.F.P.S., M.R.C.P., visiting physician; W. R. Snodgrass, M.A., M.B., F.R.F.P.S., assistant physician; J. Gibson Graham, M.B., Ch.B., dispensary physician.

## Ireland.

#### Royal College of Surgeons in Ireland.

At the annual election of officers of the Royal College of Surgeons in Ireland, held on June 6th, the following were appointed for the ensuing year:

*President:* Thomas Eagleson Gordon.

*Vice-President:* Richard Atkinson Stoney.

*Secretary of the College:* Sir F. Conway Dwyer.

*Council:* Sir Thomas Myles, Sir Robert H. Woods, Sir William Taylor, R. C. B. Maunsell, Sir W. I. de C. Wheeler, Sir F. Conway Dwyer, Trevor N. Smith, Sir Arthur Ball, Louis A. Byrne, Andrew Fullerton, Seton Pringle, Edward Sheridan, William Pearson, G. E. Pugin Meldon, Howard Stevenson, Louis L. Cassidy, W. Cecil P. Smyly, Arthur Chance, Patrick E. Hayden.

The new President, Mr. T. E. Gordon, has served in the office of Vice-President for over two years. He is professor of surgery in the University of Dublin. During the great war he held the rank of colonel, and was attached to the Dublin 83rd General Hospital, Boulogne. The new Vice-President, Mr. R. Atkinson Stoney, went to France with the French Red Cross in December, 1914; after working with the French Red Cross he was given a commission in the French Army Medical Service, and was made consulting and operating surgeon to the 5th Section of the 17th Region. He returned to Dublin in June, 1915, and went out again for the spring and summer months of 1916, 1917, and 1918. After the war he was made Chevalier of the Legion of Honour.

#### McKisack Memorial.

As announced in the *Journal* of April 21st (p. 686) it has been decided to establish a permanent memorial to the late Dr. Henry Lawrence McKisack, consulting physician to the Royal Victoria Hospital, Belfast, who died on March 26th, and in this connexion a meeting of subscribers to the memorial fund was held at the hospital on June 1st. Mr. T. S. Kirk, chairman of the medical staff, presided, and it was reported that contributions amounting to £555 had been received to date. The meeting decided to erect a bronze memorial tablet in the hospital and to employ the remainder of the sum in hand to constitute the nucleus of a McKisack Research Fund, the income from which will be devoted to the study of diseases, injuries, and deformities in all their aspects, including the study of the results of treatment. The fund is to be kept open for future donations, with no limitation as to amounts, and is to be entrusted to the Board of Management of the Royal Victoria Hospital for administration on the recommendation of the visiting medical staff. A committee, consisting of Mr. T. S. Kirk, Mr. Edwin D. Hill, Mr. Stanley Ferguson, Dr. Robert Marshall, and Dr. Andrew Trimble, was appointed to put into effect the decisions of the meeting.

#### The Medical Profession and the Public.

At a recent meeting of the Statistical and Social Inquiry Society, held in the Royal Academy, Dublin, Dr. R. J. Rowlette, read a paper on the relations of the medical profession and the community. The General Council of Medical Education and Registration, he said, was not necessarily composed of medical practitioners and was not elected by medical franchise. It was a grievance that the unqualified practice of medicine was not more completely prohibited. The Council existed for the protection of the public and not of the profession. Referring to the Medical Practitioners Act (Irish Free State), 1927, he indicated

certain departures from the British system. As to the degree of sanctity of professional confidence, he drew a comparison between the privilege of legal and medical communications, and pointed out some anomalies of medical practice. Sir William Thompson, in proposing a vote of thanks to Dr. Rowlette, said it was well that the public should know something about the work and aims of the medical schools of the universities and colleges, and about the amount of time certain members of the medical profession gave to this work. It was only families who had members in the medical profession who knew the many difficulties and adverse circumstances doctors had to contend with. The relation of the medical profession to public health was of ever-increasing importance, as the prevention of disease was now taking such an important part in the life of the profession and the community. The amount of voluntary service rendered by the medical profession was not sufficiently realized, for in hospitals, public appointments, dispensaries, and in private practice also, much time was devoted to charitable work. Dr. Moorhead, in seconding, expressed the view that a doctor brought before the General Medical Council or the Irish Medical Council on any disciplinary charge should have the right of appeal to the law courts, if he was dissatisfied with the decision.

## England and Wales.

#### Maternal Mortality: Appointment of Departmental Committee.

SHORTLY before the Whitsuntide recess Mr. Chamberlain, the Minister of Health, as a part of the measures designed to combat maternal mortality and morbidity, to which he referred when introducing the Estimates of the Ministry of Health in the House of Commons on May 15th, appointed a Departmental Committee to consider the working of the Midwives Acts, with particular reference to the training of midwives and the conditions under which they are employed. The names of that Committee and its terms of reference were given in the *Journal* of May 26th (p. 917). As a further instalment of the measures referred to Mr. Chamberlain has now appointed a second Departmental Committee, whose terms of reference are to advise upon the application to maternal mortality and morbidity of the medical and surgical knowledge at present available, and to inquire into the needs and direction of further research work. The personnel of this purely medical committee is as follows: Sir George Newman (chairman), Professor F. J. Browne, Dame Janet M. Campbell, Mrs. Ethel Cassie, Dr. Leonard Colebrook, Professor Archibald Donald, Dr. C. E. S. Flemming, Sir Walter M. Fletcher, Dr. Harold Kerr, Dr. W. H. F. Oxley, Professor Miles H. Phillips, Dr. C. E. Tangye, Dr. O. L. V. S. de Wesselow. The secretary of the Committee will be Dr. Margaret Hogarth of the Ministry of Health, Whitehall, S.W.1, to whom all communications relating to the work of the Committee should be addressed.

#### Wembley Hospital.

The Duke and Duchess of York opened on June 2nd the new hospital which has been erected at Wembley at a cost of about £20,000. The building is situated behind the main road on a site presented by Mr. G. Titus Barham, chairman of the board of management, who also contributed generously towards the building expenses. At present there are twenty beds, but it will be possible to double the accommodation at a cost of £3,000, and to extend the capacity of the institution to a hundred beds in the future should this become necessary. Two wards, for men and women respectively, contain six beds each; there is a children's ward of four beds, named after Princess Elizabeth, and two rooms, each with two beds. A fully up-to-date operating theatre and a well-equipped x-ray room have been provided. The building opens free from debt, the necessary money having been collected—mostly, locally, through a contributory scheme—during the last three years. About £2,000 was obtained in large donations,

and substantial grants were received from King Edward's Hospital Fund. All the practitioners in the district become automatically members of the ordinary staff of the hospital, and there is a consulting staff numbering fourteen.

#### Presentation to Dr. B. E. A. Batt.

For many years Dr. Bernard E. A. Batt has rendered great service to the medical profession in West Suffolk. In his capacity as honorary secretary to the West Suffolk Division of the British Medical Association, and as chairman (previously honorary secretary) of the Panel Committee, he has done an immense amount of work. At a meeting of medical practitioners held on May 31st at Bury St. Edmunds Dr. J. S. Hinnell referred in warm terms to the appreciation of all medical men in the county of Dr. Batt's activities in the interests of the profession and of the West Suffolk Hospital and its patients. As a small mark of that appreciation he handed to Dr. Batt a cheque representing donations readily made by the whole of the local medical profession, and asked him to realize their thanks for all his good work. Dr. Batt, for once at a loss on the matter before the meeting, made a brief reply, saying that he had enjoyed the work, that it added to his pleasure to know that he was helping and that that help was appreciated, but he was unable to find the right word to express his thanks.

## Correspondence.

### DIRECT REPRESENTATION ON THE GENERAL MEDICAL COUNCIL.

SIR,—From your report of the recent proceedings of the General Medical Council it appears that there are now two vacancies on that body from among those who are elected to represent the medical profession directly, and an election to fill these vacancies is to take place in the autumn.

This gives us time to consider carefully who are to represent us, and I want at once to press the view that both these should be general practitioners with an intimate knowledge of national health insurance as well as of other branches of general practice. If two practitioners, still in active practice, can be found to give the time, I hope they will be strongly supported. It would be, of course, a further advantage if one of them is engaged in industrial and the other in rural practice. At present Dr. Brackenbury is the only general practitioner on the General Medical Council, and, invaluable as his services are, this amount of representation is very insufficient.

The great majority of the members of the General Medical Council are teachers representing the universities and colleges, and many of them are whole-time officers without any personal experience of the practising side of medicine, or of the relationships between doctor and doctor and patient and doctor, with their variations in different types of practice and differing circumstances.

It seems essential that on a body charged, among its many other duties, with the supervision and control of these relationships a much more sufficient representation of the practising doctor should be found.—I am, etc.,

Birmingham, June 4th.

H. GUY DAIN.

### MEDICAL CO-EDUCATION.

SIR,—The question of co-education in medical schools is one which has been occupying the attention of the Medical Women's Federation since the recent pronouncement in the press that certain schools had agreed to close their doors in future to women students. In the correspondence which followed, statements were made in regard to the so-called "wastage" among qualified medical women, and the figure of "50 per cent. or thereabouts" was given as the proportion of those who marry and presumably thereafter cease from working at their profession.

Investigations were at once undertaken by the Medical Women's Federation to prove the truth or otherwise of these statements. A questionnaire was sent to the one thousand members of the federation living in the British Isles. The point of interest which emerges is the small

percentage of those who have retired from their profession, especially as the figure includes a number who only retired after many years of active and successful medical practice.

General practice	...	...	40.6 per cent.
Hospital or institutional work	...	...	12.7 "
Consulting and specialist	...	...	14.0 "
Research	...	...	3.6 "
Public health	...	...	15.6 "
Retired	...	...	9.0 "
Not ascertained	...	...	4.5 "

Steps were also taken to ascertain details regarding the women who had qualified at six London hospitals. From the following figures it will be seen that instead of the "50 per cent. or thereabouts" stated to marry and so become lost to the profession, the actual number is under 10 per cent.

The number of women qualified from the Royal Free Hospital (for the years 1923, 1924, and 1925), and from Charing Cross Hospital, the London Hospital, St. George's Hospital, St. Mary's Hospital, and University College Hospital, is understood to be 644. The following is an analysis of these:

Doing active medical work	...	...	76.39 per cent.
Reading for higher qualification	...	...	1.09 "
Travelling abroad	...	...	0.93 "
Temporarily unemployed at time of inquiry	...	...	6.21 "
Invalided	...	...	0.15 "
Died	...	...	0.77 "
Not traced	...	...	4.66 "
Retired	...	...	9.78 "

The percentage of those who have married is 15.99—namely:

Married and still working	...	...	6.36 per cent.
Married and retired	...	...	9.63 "

At a recent session of the Council of the Medical Women's Federation a resolution in the following terms was unanimously passed:

"That this Council of the Medical Women's Federation, while welcoming the public support which has been generously accorded to the efforts to retain the presence of women in co-educational schools, deprecates any attempt to put pressure on the hospitals concerned by urging subscribers to withdraw their subscriptions."

On behalf of the Council of the Medical Women's Federation.—We are, etc.,

CATHERINE CHISHOLM, *President.*

CHRISTINE M. MURRELL, *Past-President.*

A. E. SANDERSON CLOW and ALISON HUNTER,  
*Vice-Presidents.*

JANE H. WALKER, *Hon. Treasurer.*

F. MAY DICKINSON BERRY, *Hon. Secretary.*

London, W., May 25th.

### THE TREATMENT OF MALIGNANT DISEASE BY COLLOIDAL LEAD.

SIR,—Knowledge of the fact that colloidal lead is a "difficult and dangerous therapeutic method" of treating malignant disease urged me to advise Professor Blair Bell to withhold details of the suspension used in Liverpool until we were satisfied that it was reasonably free from danger to life. I feared then that a premature revelation of our method would result in the promiscuous use of lead colloids of widely variable toxicity in cases of advanced malignant disease which were beyond hope from any treatment. Dr. Wyard's paper in your issue of May 19th (p. 838) fulfils in some respects my prophecy. He finds colloidal lead hydroxide, from his experience with thirty-two patients, to be "extremely toxic"; I condemned lead hydroxide to our Research Committee in 1925, at the expense of two rabbits. Dr. Wyard suggests that he followed latterly the original technique; if so, his description of it is faulty, and later he speaks of making slight alterations and of using a reducing agent. As the pharmacologist of the Liverpool Medical Research Committee it has been my duty to report on the relative toxicity of the "many times changed" methods of preparing the colloid, and I can state that, before any modification of the lead colloid has been used on human beings in Liverpool, it has previously been tested repeatedly upon both rabbits and cats in doses per kilo far exceeding those given to human beings. I do not find evidence that Dr. Wyard took such precautions.

From the standpoint of pharmacology I may say that the variation in toxicity—as judged by lethal effects and cardiac or renal detriment in animals—due to slight variations in the method of preparation or composition of lead colloids, is remarkable, and was demonstrated at Nottingham by tracings and mentioned in the epitome of my paper to the Manchester Medical Society. May I reassure your readers by saying that we are striving in Liverpool not only to obtain a lead colloid which shall be “more successful therapeutically than another,” but also one which shall be less toxic to the patient? As regards the latter criterion, improvements have been achieved, but not yet as regards the former. It may be stated that I condemned the addition of a reducing agent (sodium hydrosulphite) in 1926, and that I regard the following colloidal preparations as dangerous: lead saccharate, lead mannitol, lead glycinate, lead complex with catechol, lead fluoride. Colloidal lead selenide is safe, but appears to be devoid of inhibitory effect in malignant disease. As one who has viewed the remarkable results of the colloidal lead treatment in Liverpool, I shall regret if the publication of the method leads to the trial of unsafe preparations in apparently hopeless cases, and deplore that I did not deem it humanitarian to publish records of all the lead derivatives which I condemned as dangerous upon pharmacological grounds.—I am, etc.,

WALTER J. DILLING.

Department of Pharmacology, University  
of Liverpool, May 28th.

### THE PATHOGENESIS OF ACUTE PRIMARY GLAUCOMA.

Sir,—In his letter which appeared in the *Journal* of May 26th (p. 919) Dr. McQueen takes some exception to the views of Dr. Maitland Ramsay on the question of the origin of the aqueous humour as expressed in his lecture on the pathogenesis of acute primary glaucoma. Dr. Ramsay suggested that the evidence was in favour of the formation of this fluid by dialysis in the same manner as the other tissue fluids, and to this Dr. McQueen objects on two grounds: first, that there is not a sufficient pressure in the capillaries of the eye to allow such dialysation, and secondly, that the aqueous humour is formed in quantity too great to be accounted for in this way.

With regard to the first objection, the capillary pressure in the eye has never been measured; nor, indeed, is this likely to be possible. Dr. McQueen merely argues from analogy: “Elsewhere in the body the loss of pressure between capillaries and veins is 1 to 2 mm. of Hg... the main loss of arterial pressure in the body is in the arterioles.” The obvious reply may be that it is dangerous to argue from the rest of the body and apply the conclusions to the eye; but apart from this, it is by no means generally agreed that these statements are correct. The very many attempts which have been made to estimate capillary pressure have produced a peculiarly discordant and bewildering set of results; the measurements made by Leonard Hill are low, others are higher. Some of them taken within the last few years are these: Landerer (1913), 17 to 25 mm. Hg; Goldmann (1914), 5 to 8 mm.; Kranss (1914), 6 to 9; Briscoe (1918), 20; Danzer and Hooker (1920), 22; Hill (1920), 2 to 4; Basler (1921), 7; Boas and Frant (1922), 18 to 22, and up to 60 pathologically; Kylin (1923), 8 to 14, and up to 50 pathologically; Liebesny (1923), 15 to 40; White (1924), 3 to 14; Carrier and Rehberg (1923), 3 to 6; Landis (1926), 10 mm. Hg. It is true that most of the methods which have been employed lend themselves to criticism, but the fact of disagreement is obvious. Moreover, all of them have been taken in the skin, or in animals low down in the evolutionary scale, and there seems little justification in applying the results to the circulation of the internal organs of the higher mammals or to the very specialized conditions of the eye. Indeed, the opinion has been offered (Krogh, 1922; Liebesny, 1923) that in the skin there are few arterial capillaries, and that the pressures recorded here are largely of the nature of venous-capillary pressures.

The disagreement in the results is probably to be accounted for by the fact of the great variability of the capillary pressure. In the light of the recent work of Krogh, Dale, Lewis, and others the capillaries are not to be thought of as a static part of the circulation, and the blood pressure in them as a constant and measurable quantity; but they are to be looked upon as the most active, purposive, and dynamic part of the whole circulation, with a pressure continually varying from individual to individual, from organ to organ, and from time to time. The capillary pressure does not appear to be wholly dependent upon the arteriolar pressure or regulated entirely by the arteriolar nerves; they have, on the contrary, a special capillariomotor mechanism, partly nervous and partly chemical, which endows them with an active tonicity suggesting that the peripheral resistance is not confined to the arteriolar region, but that no inconsiderable part of it, and therefore of the fall of pressure, is located in the capillaries. In the human skin, where the capillary pressure is undoubtedly low, Lewis (1924) estimated their contractile power as being capable of expelling fluid against a pressure of 50 to 60 mm. Hg, and when contracted, of resisting the entry of fluid up to 90 or 100 mm. Hg. These deductions have received striking confirmation in the recent work of Dale and his collaborators, who, dissociating the arteriomotor and capillariomotor effects, have brought forward a large amount of evidence to show that “the peripheral resistance is not limited to the arterioles, and that the common assumption is unwarranted that there exists an abrupt fall of pressure in this part of the circulation.” Such a conception—that the fall of pressure is evenly distributed—has been confirmed by the measurements of Landis (1926), who, introducing a micro-pipette into the peripheral vessels of the frog’s mesentery, found that there was no sharp fall of pressure in the arterioles, but that the decrement continued evenly throughout the capillary bed. Landis, who used a very unequivocal technique, found that the pressure in these arterial capillaries was 145 mm. H<sub>2</sub>O above the tissue pressure—just the amount required to overcome the osmotic pressure of the tissue fluids in that animal. His results and those of White (1924) agree in that the average pressure in the arteriolar end of the capillary is above, and that in the venous capillary is below, the colloid osmotic pressure, so that free interchange of fluid is possible throughout the length of the capillary. I can see no unreasonable objection, in the light of our present knowledge, for assuming that in the human eye the capillary pressure is 25 mm. of mercury above the tissue pressure there (that is, the intraocular pressure). In any case, the modern conception of a dynamically active capillary bed and an ever-changing capillary pressure makes it seem unreasonable to speak of a capillary pressure at all, and suggests that it may be dangerous to reason too closely from one set of circumstances to another.

With regard to the second point, that 6 c.mm. of aqueous are formed per minute, I am unaware on what evidence this estimate is given. I have elsewhere<sup>1</sup> criticized the experimental technique on which the estimations in the literature have been based, and have pointed out that the results have all been deduced from experiments in which the eye has been opened, or wherein completely abnormal pressure conditions have been introduced. Evidence based upon the chemical changes occurring in the aqueous is much less open to criticism, and the only conclusion which can be reached from this is that the interchange of fluid in the eye is very much less than has generally been supposed, and is quite in accordance with the requirements of a hypothesis of dialysation.

Nevertheless, Leonard Hill is almost certainly quite correct in his main contention. It is not the push of the capillary pressure which is the essential point in the etiology of glaucoma, but the permeability of the capillary walls and the pull of the tissue cells resulting from an altered metabolism in the eye. Dr. Maitland Ramsay dealt largely with the first of these influences; changes in the vitreous are probably the most important factor in the second.—I am, etc.,

London, W.1, May 28th.

W. S. DUKE-ELDER.

<sup>1</sup> The Nature of the Intraocular Fluids, *British Journal of Ophthalmology*, Monograph Supplement, 1927.

Sir,—There will probably always exist, and always have to be combated, an unfortunate prejudice against the secretory theory (as opposed to theories of filtration, dialysis, etc.). This prejudice arises on quite extraneous—I mean unscientific—grounds. It is the idea that to deny that the behaviour of the living cell can be deduced from the boy's first book (or any existing book) of physics is equivalent to investing the cell with occult powers.

It cannot be too strongly asserted (though it is nauseating to have to assert it at all) that the secretory theory would not be a scientific theory if it sought to confer upon the cell any measure whatever of supernatural activity. It is only in the minds of those who have fainted upon the scientific way that the secretory theory has any connexion with "vital force," "biotic energy," "neovitalism," or any such refuge of the destitute.

To conclude on the evidence available that rather crude hypotheses like those of filtration, dialysis, etc., may (in view of the great complexity and delicacy of living matter) prove to be reductions to a simplicity which is absurd is perfectly scientific, and, whether the conclusion itself is right or wrong, it voices no greater heresy than does the suggestion that a man may act differently from a corpse.

The secretory theory merely emphasizes the fact that matter which has attained that peculiar degree of complexity which constitutes aliveness is apt to behave otherwise than matter which has not this complexity. No metaphysical theory whatever is involved or implied, and not the slightest departure is made from that working hypothesis of absolute materialism (or absolute objectivity) which is the inalienable basis of all scientific knowledge.—I am, etc.,

Liverpool, May 29th.

BERNARD CRAVASSER.

## THE ORIGIN OF ISCHAEMIC CONTRACTURE.

### *The Case of Tyndall v. Alcock.*

Sir,—Mr. Edward Thompson (June 2nd, p. 961) should not censure Mr. Roth (May 26th, p. 921) for his comments on Professor Hey Groves's article on this case (May 12th, p. 807). Mr. Roth at least suggests a valuable point which will help others to avoid the advent of this nightmare—*ischaemic contracture*—which, as those engaged in orthopaedic practice know so well, is far less rare than Mr. Thompson's fortunate experience would suggest. Mr. Thompson's note is merely a genuine expression of the sympathy which, of course, all of us feel for Dr. Alcock, but it adds nothing whatever to guide us in preventing the occurrence of this grave complication.

Mr. Roth did not stress the point which I am sure he had very much in mind—namely, that "full flexion," as advocated in the books, is a factor equal in importance to tight bandaging in the production of ischaemic contracture. If the forearm in relation to the upper arm is "5 minutes past" (to use a clock nomenclature) the evil is likely to occur. On the other hand, putting the elbow up at "7 or 10 minutes past"—that is, 40 to 60 degrees—will be safe.

Supporting Mr. Roth's point, I would mention that one of the worst cases I have seen followed bandaging of the upper forearm, for a graze, by a village nurse. Of two cases that have happened to myself, one followed "full flexion" ("5 minutes past") and the other on tight bandaging of the forearm after plating a forearm fracture (without flexion), although, fortunately, being alive to the possibility, I got in on the problem before more than a temporary damage had occurred to the flexor muscles of the index finger.

Professor Hey Groves himself, in his article, makes no very helpful deductions to guide us in the anticipation and prevention of the condition. I agree with him that the displacement of bone fragments has no importance whatever in the production of ischaemic contracture. That it is a dangerous thing to flex a swollen elbow-joint I have already admitted; but he puts forward the old fallacy that the existence of the radial pulse is the index of safety. This is a snare and a delusion, and, if I may be allowed to say so, very bad teaching. I have had the condition occur under my most intense observation while

believing that all was right as long as the radial pulse could be felt.

The threatening symptoms are pain, pain, pain! associated with lividity and swelling, and disinclination for active movements of the hand and fingers. Relieve these symptoms immediately, and if this is done within the first twelve or twenty-four hours all will be well. Have no regard for the fracture; phy for safety where the circulation is concerned. The fracture and the function of the elbow can always be relieved subsequently, but, in spite of Professor Hey Groves's statement of Sir Robert Jones's opinion on the improvement that is possible in the Volkmann complication, I maintain that present-day methods in most cases can do nothing more for ischaemic contracture than improve the cosmetic appearance of the hand and forearm.

Several other points in Professor Hey Groves's article are open to discussion, and I should like to take them up with him; but please save me from going "exactly counter, as so often happens in our profession," which, as Mr. Thompson maintains, Mr. Roth did "without reason." Mr. Roth had, indeed, every reason to communicate the results of his considerable experience for the benefit of all those who have had to deal with these elbow fractures, and his remarks are not lightly to be turned down by Mr. Thompson, while the subject is so fresh in our minds, as being beside the point.—I am, etc.,

W. H. TRETOWAN,

Guy's Hospital, and the Royal National  
Orthopaedic Hospital.

London, June 5th.

Sir,—With regard to the origin of ischaemic paralysis, surely Mr. Roth will admit that a vascular lesion unassociated with fracture may produce this condition.

A few months ago I was called to a young girl, whose arm was lying on a pillow, extended at the elbow. On examination I noticed that the limb was cold, and found that she had no radial pulse. The supracondylar fracture was easily reduced, and the arm treated in the fully flexed position. A perfect anatomical and functional result followed, but the radial pulse had not reappeared eight weeks later. I take it that the radial pulse may disappear at once by pressure of fracture ends or during the next three or four days by thrombosis. It would be interesting to know if any orthopaedic surgeons have statistics of the absence or disappearance of the radial pulse in their wide experience of fractures about the elbow.—I am, etc.,

Liverpool, June 4th.

R. KENNON, F.R.C.S.

## TETRA-ETHYL LEAD IN MOTOR SPIRIT.

Sir,—In the report of the second public meeting of the Committee of Inquiry on Tetra-Ethyl Lead in Motor Spirit which appeared in the *British Medical Journal* of May 19th (p. 871) there are several misquotations of the evidence I submitted. Thus reference is repeatedly made to two men (mechanics) who, it is erroneously stated, were medically examined by me. These men were examined, independently, by their own private doctors, and also, independently, by an expert clinician engaged in lead examinations of cancer patients undergoing lead chemotherapy. I was not consulted in these examinations, but I thought it proper to record, without comment, in my memorandum of evidence a statement of these independent clinical findings, for which I have no responsibility. The only submission I make in this connexion is that, in the circumstances of an additional exposé to lead, it is justifiable in the interests of the men themselves that they be kept under medical observation—the stricter the better. (I assume that these mechanics are habitually exposed to a small lead occupational risk.)

I regret that my memorandum of evidence, of which, as specially requested by the secretary to the committee, I had furnished a sufficient number of copies for circulation to the press, was not so distributed; had it been circulated these misquotations could not have occurred.

Numerous misquotations of the evidence have appeared in the lay press, and the *Times*, in its issue dated May 16th, not only makes the above misquotation, but also

purports to give details of my (alleged) evidence with regard to experiments on monkeys. I have carried out no animal experiment of any description in connexion with this investigation.

The crux of the whole matter is that, in the recent experiments conducted by the Research Association of British Motor and Allied Manufacturers with regard to exhaust gases from engines burning leaded spirit as a motor fuel, and also as the outcome of the investigation of the deposits found in three motor vehicles after a mileage of 11,000, the run being entirely with leaded spirit, it was found that not less than 80 per cent. of the lead contained in the fuel was discharged into the atmosphere, and also that the exhaust gases contain not less than from twenty to fifty times the amount of lead per cubic metre as was obtained in exhaust gases in the tests as described in the *Bulletin* (No. 2661) of the United States Bureau of Mines of December, 1924. Also in one of the tests recently carried out in England with a stationary engine it was found that the water vapour of the exhaust gases which can be condensed from the end of the exhaust pipe is capable of dissolving practically the whole of the lead present in the exhaust gases. In short, with exhaust gases from an engine burning leaded motor fuel we are dealing with large quantities of water-soluble lead.

May I correct a misapprehension which prevails as the outcome of the following sentence which appeared in the *British Medical Journal* on January 14th, 1928 (p. 61): "The high toxicity of this compound naturally aroused alarm in the United States, and its use was for a time prohibited in the city of New York." The actual significant fact is that the sale of ethyl gasoline (ethyl petrol) is still banned in New York City.—I am, etc.,

Hendon, May 27th.

MYER COPLANS, M.D.

#### THE INTRAVENOUS INJECTION OF INDIGO-CARMINE.

Sir,—I noticed in the report of a paper read by me before the Royal Medico-Chirurgical Society of Glasgow, and epitomized in the *British Medical Journal* of December 10th, 1927 (p. 1087), it is recorded that in the investigation of patients suffering from renal tumours I use "an intravenous injection of 5 c.cm. of a 4 per cent. solution of indigo-carmin." This was such an obvious clerical error that at the time it did not occur to me to correct it. As Mr. Alex. E. Roche has called attention to it in your issue of May 26th (p. 921) and considers that others might be tempted to adopt the percentage stated with the dire results he has brought to the notice of your readers, I hasten now to correct it. The original manuscript and my paper published in the April number of the *Glasgow Medical Journal* give the percentage correctly—namely, 0.4 per cent.—I am, etc.,

Glasgow, May 30th.

WALTER W. CALDWELL.

#### ARSENIC IN SUGAR.

Sir,—Some years ago, when medical officer of health to a rural district, I received a request from the Ministry of Health to make investigations into a case of suspected poison in sugar.

The sack of sugar in question had travelled from London in the same truck as a drum of disinfectant. The grocer who received the sugar used one sack of the two which constituted the consignment, but, noticing a smell about the other, reported it. I followed up the drum of disinfectant and sent part of the contents to be analysed, also some of the sugar. The report from the Ministry came back stating that the disinfectant was crude carbolic acid, containing no arsenic, and that the sugar was loaded with arsenic, and the sample sent contained sufficient to poison the whole of the inhabitants of the village.

Luckily the disinfectant had imparted an odour to the sack against which it was placed. I was not informed as to the source of the sugar, and have often wondered how many more sacks there were like it, and how many of us contain arsenic in appreciable quantities.—I am, etc.,

Totnes, May 28th.

I. M. JEFFERISS.

## The Services.

### INDIAN MEDICAL SERVICE DINNER.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant, London, on Wednesday, June 20th, at 7.15 p.m., under the chairmanship of Major-General Sir R. Havelock Charles, Bt., G.C.V.O., K.C.S.I. Price of dinner tickets, 16s. 6d. to subscribers and £2 to non-subscribers. Further particulars may be obtained from the joint honorary secretary, Major Sir Thomas Carey Evans, M.C., I.M.S.(ret.), 31, Wimpole Street, W.1.

### DEATHS IN THE SERVICES.

Lieut.-Colonel Dermot Owen Hyde, C.B.E., D.S.O., R.A.M.C., died at Maymyo, Upper Burma, where he was in command of the station hospital, on April 19th, aged 50. He was born on December 1st, 1877, the son of Lieut.-Colonel Robert Hyde, A.M.S., and educated at Trinity College, Dublin, where he graduated as B.A. in 1896 and as M.B. and Ch.B. in 1899. Entering the army on April 25th, 1900, he attained the rank of lieutenant-colonel on December 25th, 1917. He served in the South African war in 1901-02, receiving the Queen's medal with two clasps, and also in the recent great war. In 1911 he was appointed to the West Riding Division of the R.A.M.C.(T.F.), and went out with that division to France. In the battle of the Somme, in 1916, he commanded the 14th Field Ambulance, from February, 1917, to April, 1918, he was in command of No. 1 Casualty Clearing Station, and from April, 1918, to March, 1919, was A.D.M.S. of the 21st Division. After the war he served for three years, 1919-22, as senior medical officer at Bermuda; and in 1922 was A.D.M.S. of the 28th Division in the Dardanelles. He was mentioned in dispatches in the *London Gazette* of June 15th, 1916, and January 4th, 1917, and received the D.S.O. and the C.B.E. for his services. In 1903 he married Hilda Edith Richmond, daughter of Lieut.-Colonel F. de R. Manduit, and leaves a widow and two sons.

Lieut.-Colonel James Havelock Alexander Rhodes, R.A.M.C. (retired), died at Pontac, Jersey, on April 10th, aged 71. He was born on January 14th, 1858, took the M.R.C.S. and L.S.A. in 1880, entered the army as surgeon on February 5th, 1881, became lieutenant-colonel after twenty years' service, and retired on April 19th, 1911. He rejoined for service during the late war, from April 14th, 1915.

Major Alexander Yates Reilly, R.A.M.C.(ret.), died on January 2nd, aged 65. He was born at Dakka, in Bengal, on May 22nd, 1862, and was educated at Durham University, where he graduated as M.B. and M.S. in 1885; also taking the M.R.C.S. and the L.S.A. in 1884, the L.R.C.P. Lond. in 1886, and the F.R.C.S. Ed. in 1889. Entering the R.A.M.C. as surgeon on February 5th, 1887, he became major after twelve years' service, and retired on June 22nd, 1907. He served in the Sudan, in the Dongola campaign of 1896, receiving the Egyptian medal and the Khedive's bronze star; in the Sudan campaign of 1898, when he was present in the battles of the Atbara, River and of Khartoum, was mentioned in dispatches in the *London Gazette* of September 30th, 1898, and received the medal for that campaign and two clasps to his Egyptian medal; and in the South African war, in 1902, in operations in the Transvaal, receiving the Queen's medal with four clasps. He also rejoined for service in the recent great war in August, 1914.

## Universities and Colleges.

### UNIVERSITY OF OXFORD.

DR. CHARLES S. MYERS, F.R.S., has been appointed Herbert Spencer lecturer for 1929.

### UNIVERSITY OF CAMBRIDGE.

THE following have been appointed members of the Degree Committee in the Faculty of Medicine: Dr. T. S. Hele, Professor G. H. F. Nuttall, Sir Hugh Anderson, Dr. W. L. H. Duckworth, Dr. E. D. Adrian, and Mr. H. Thurkill.

### SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

**SURGERY.**—M. K. Bryce, H. M. Feldman, A. H. Hennessey, N. C. R. Keukenschrijver, C. P. Madden, H. D. K. Wright.  
**MEDICINE.**—K. D. C. Beckett, L. J. Corbett, N. C. R. Keukenschrijver, A. A. Leibovitch, L. W. Sanders.  
**FORENSIC MEDICINE.**—A. C. Banerji, H. I. Jones, N. C. R. Keukenschrijver.

**MIDWIFERY.**—M. K. Bryce, N. C. R. Keukenschrijver, A. E. Vawser.

The diploma of the Society has been granted to Messrs. K. D. C. Beckett, L. J. Corbett, H. I. Jones, N. C. R. Keukenschrijver, and L. W. Sanders.

## Obituary.

SIR JAMES HODSDON, K.B.E., M.D., F.R.C.S.Ed.,  
Member of the General Medical Council; President of the  
Royal College of Surgeons of Edinburgh, 1914-17.

As recorded with regret in our last issue, Sir James Hodsdon died suddenly on May 28th, while returning to Edinburgh from London after the summer session of the General Medical Council. For some years his health had given anxiety to his friends, but he seemed on the day preceding his death to be in ordinary health and vigour. After retiring to his sleeping berth in the train, he had laid down without undressing, and was found dead by the train attendant between 6 and 7 o'clock next morning.

James William Beemua Hodsdon was born in Bermuda in 1858, and, coming to England at the age of 13, completed his school education at Sherborne. After commencing medical study at Queen's College, Belfast, in 1875, he went to Edinburgh in 1877 and became a licentiate of the Royal College of Surgeons in 1880. He proceeded in 1883 to the Fellowship of the Royal College of Surgeons and to the Membership of the Royal College of Physicians of Edinburgh. Meantime, in 1881, he had graduated M.D. at Queen's University, Belfast. He became, in the summer of 1880, house-physician to Dr. Brakenridge, one of the physicians in the Royal Infirmary, Edinburgh, having as one of his fellow residents the late Dr. Alexander Bruce, and a year later, in the winter session 1881-82, he became house-surgeon to Mr. John Duncan, with whom he maintained a close connexion for many years. In the meantime he had acted as a resident physician in the Sick Children's and Maternity Hospitals, and had spent a period in foreign study, during which he visited

the medical schools of Vienna, Paris, and London. Having a natural bent towards surgery, Mr. Hodsdon acted as assistant to Mr. John Duncan and later as extra-mural lecturer on surgery. In the latter capacity he was a highly successful teacher, being very popular with students in the early years of the present century as a clear and concise lecturer, and attracting for many years a very large class. While acting as lecturer on surgery he served at various times as examiner in surgery and clinical surgery in the Universities of Edinburgh, Durham, and Belfast. In 1886 he was elected assistant surgeon to the Royal Infirmary and in this capacity was again associated with Mr. John Duncan, and, after assisting him for many years in private practice, succeeded him as chief medical adviser to the Scottish Provident Insurance Company. In 1909 he contested the appointment to the chair of surgery, vacant on the resignation of Professor Chiene, but was defeated by the late Professor Alexis Thomson, and at that time gave up his highly successful extra-mural class in surgery.

From the time of his election as an assistant surgeon to the Royal Infirmary, Mr. Hodsdon maintained a close

connexion with this institution, becoming successively surgeon in 1907, consulting surgeon in 1922, and a member of the board of management in 1923. The last appointment he still held at the time of his death. He was a very active member of the board, and took a great interest in the arrangements now in progress for revising the agreement in regard to clinical teaching in Edinburgh between the managers of the Royal Infirmary, the University, and the School of Medicine of the Royal Colleges. A few years ago he devoted a great deal of time and energy on behalf of the Royal Infirmary to the reorganization of the radiological department, visiting similar centres elsewhere to investigate modern developments in this direction. The new department in the Royal Infirmary, which is regarded as one of the finest in the country,

was, to a large extent, his creation.

He had taken an active part in the deliberations of the General Medical Council since 1906, when he was elected to represent on that body the Royal College of Surgeons of Edinburgh, of which from 1914 to 1917 he was president. He was also a member of the Dental Board of the United Kingdom after the establishment of that body in 1921, and for a number of years had been chairman of the governing body of the School of Medicine of the Royal Colleges at Edinburgh.

Sir James Hodsdon had a long and intimate connexion with the British Medical Association. He had been joint honorary secretary of the Edinburgh Branch from 1898 to 1901 and vice-chairman of the North-West Edinburgh Division for several years prior to the amalgamation of the three original Edinburgh Divisions into one Edinburgh and Leith Division as at present. He was also chairman of the North-West Edinburgh Division in 1905, a representative of this Division to the Annual Representative Meeting in 1904, and

its representative on the Edinburgh Branch Council from 1904 to 1907. In connexion with the Edinburgh Meeting of the Association in 1927 he took an active part in the organization, being chairman of the committee which arranged the annual dinner in the Music Hall at Edinburgh.

In the midst of a busy administrative life he found time to make some contributions to current medical literature, and was the author of the article on the palate in the *Encyclopaedia Medica*. He contributed an article on excision of the sigmoid for carcinoma, when that operation was comparatively new, to the second volume of the *Edinburgh Hospital Reports*. Between 1888 and 1891 he had also contributed to the *Edinburgh Medical Journal* an inquiry into the method of cure in empyema, and to the *Lancet* an experimental inquiry into the influence of the pulmonary blood pressure upon the collapsed lung.

During the war he rendered valuable services as a member of the surgical staff of the 2nd Scottish General Hospital at Craigleith. He was also for some time the surgical member of the special medical board for Scotland which reviewed the decisions of the various medical boards

SIR JAMES HODSDON.

in Scotland in regard to recruiting, and he was, in the later stages of the war, a member of the Scottish Medical Service Emergency Committee. He acted for the Ministry of Pensions as a member of the Advisory Medical Council for the Scottish Area, and in this connexion arranged for the building, equipment, and staffing of the orthopaedic annexe at Tynemouth, Edinburgh. In recognition of these services he received the C.B.E. in 1919, and was created K.B.E. in 1920.

He was a keen sportsman, and for more than thirty years his annual holiday had been spent in sea trout fishing at Lochboisdale in the Outer Hebrides. Another favourite relaxation was shooting. His administrative capacity was universally recognized, and his advice was constantly sought on difficult and intricate questions affecting medical affairs. His death will be felt not only as a personal sorrow to many private and professional friends, but will be a great loss to the various public bodies and committees of which he was an active and valued member.

Sir James Hodsdon was married to Joan, daughter of the late Mr. William Raffin of Edinburgh, by whom he is survived. The interment took place on May 31st in the Dean Cemetery, and was attended by a large number of representatives of the medical profession and of various organizations, including the Royal College of Surgeons, the Royal Infirmary, and the Royal College of Physicians, with which he had been officially connected.

The photograph reproduced on page 1003 is by A. Swan Watson, Edinburgh.

**GEORGE EDWARD SHUTTLEWORTH, M.D.,**  
Formerly Medical Superintendent, Royal Albert Asylum,  
Lancaster.

It is with great regret that we have to announce the death, on May 28th, at the advanced age of 86, of Dr. G. E. Shuttleworth. Although he retired from practice several years ago, he was for so many years the leading authority in this country on mental deficiency, and the author of such a widely read book on this subject, that there can be few psychiatrists throughout the civilized world to whom his name is not familiar. To many members of the medical profession in this country, even the junior ones, he was a well-known and revered figure, for, although he had outlived most of his contemporaries, he continued long after his retirement to attend and speak at meetings relating to the subject to which he had devoted his life. By his passing the medical profession, and psychiatry in particular, have lost a member of outstanding prominence; while his character and personality were such that those who knew him mourn the loss of a warm-hearted friend and a sage counsellor, who was ever ready to give his services in the cause of the needy and distressed.

George Edward Shuttleworth was born at Edgbaston on November 16th, 1842. He went to the City of London School, and on leaving there proceeded to King's College, London, where he graduated B.A. with honours in physiology. He subsequently obtained the M.R.C.S. and L.S.A. diplomas, and the M.D. degree of Heidelberg. After working for a time at the Kilburn Dispensary he was appointed assistant medical officer to the Earlswood Institution for Defectives, the superintendent being the well-known Dr. J. Langdon-Down. Here he remained until 1870, when he was chosen, out of a large number of candidates, to be medical superintendent of the Royal Albert Asylum at Lancaster. He occupied this position for twenty-three years, and his intense keenness in his work, his wide knowledge and outstanding ability, his skill in originating and applying methods of training, brought that institution into the first rank of establishments for the care of the mentally defective, and gained for it a reputation which attracted visitors, not only from all parts of the United Kingdom, but from distant parts of the world. In this work Shuttleworth's knowledge of physiology stood him in good stead, and his methods of training were based upon sound physiological principles which received the warm approval of the great Dr. Seguin when he paid a visit to the institution. Although some improvements have naturally been made in the apparatus used for

teaching, the principles adopted and described at that time by Seguin in America and Shuttleworth in England are those which are in use at the present day.

On leaving the Royal Albert Asylum, Dr. Shuttleworth came to London and took up consulting work. His reputation caused him to be at once accepted as the leading authority regarding mental defectives. But he did much more than consulting work. He had long realized that the unfortunate mentally defective section of the community had claims to consideration and to care and training which, in the great majority of cases, were denied them, and he spent his time and energy unsparingly in arousing professional and public interest on their behalf. In his work of advocating their claims, of organizing and speaking at meetings, and instructing and training teachers, he had the enthusiastic support of a little band of devoted workers, chief among whom were Miss Ethel Dixon, Miss Bertha James, and Miss M. McDowall. In time each of these disciples became a new centre for the training of those who purposed to undertake the care of defectives, and there is no doubt that a very large proportion of such teachers owe their knowledge, directly or indirectly, to the work which was initiated by Dr. Shuttleworth. From 1899 to 1901 he was medical examiner of defective children under the London School Board, and from 1901 to 1905 medical expert to Rochester House Institution under the Metropolitan Asylums Board. His unique knowledge of the subject made him a most valuable member of the Departmental Committee of the Board of Education, the report of which led to the passing of the Defective and Epileptic Children Act of 1899. He also took a leading part in securing the passage of another valuable measure—namely, the Asylum Workers' Superannuation Act of 1909.

Dr. Shuttleworth was a member of the British Medical Association of over sixty years' standing. He served on the central Council from 1899 to 1903, and had been President of the Lancashire and Cheshire Branch in 1892. He was honorary secretary of the Section of Psychology at the Annual Meeting in 1883, and Vice-president of this Section in 1885 and again in 1906. He was a member of the Medico-Psychological Association from 1877, and a constant attendant at its meetings. He did a large amount of work for the St. John Ambulance Association, and in 1892, in recognition of this, he was made an honorary associate of the order. Long after he was 60 years of age his energy and love for the work were such that he continued to take an active part in the affairs of many societies of which he was a highly valued member. One of those in which he was especially interested, and where his knowledge and advice were highly esteemed, was the Central Association for Mental Welfare, of which he was for many years a vice-president. Another, in which he held a similar office, was the National Association for the Feeble-minded. He was also an active vice-president of the Child Study Society and the Society for the Study of Inebriety. King's College, London, elected him a Fellow, and in 1909 he was given the freedom of the City of London.

While perhaps Dr. Shuttleworth's chief work was that of a teacher and exponent of methods of training, he nevertheless wrote important articles in the *Encyclopaedia Medica*, Allbutt's *System of Medicine*, Hack Tuke's *Dictionary of Psychological Medicine*, and numerous journals. His most important contribution, however, was his exceedingly valuable book on *Mentally Deficient Children*, the first edition of which was published in 1895, and the fifth edition, in conjunction with Dr. W. A. Potts, in 1922.

To those who did not know him this account will give some idea of Shuttleworth's ability and energy. It is no exaggeration to say that the whole of his professional life was one of untiring devotion in the cause of mental defectives. In this work he was a pioneer, and he maintained his interest in it almost up to the end. The writer visited him only a short time before he died; in spite of his manifest feebleness his thoughts were still on his life work, and he expressed his satisfaction at the recent passing of the amended Mental Deficiency Act. Those who were fortunate enough to know him, however, will remember him for something more and perhaps even greater. They

will remember his complete lack of ostentation, at times almost amounting to self-effacement, his never-failing sympathy, his charitable judgement, his great kindness of heart, and his nobility of character. His book on mental defectives ended with the quotation "*Lateat scintilla forsan*," but it was no small spark that lay hidden behind the unobtrusiveness of Shuttleworth.

He married Edith Mary, the daughter of Henry Hindwen of Lancaster. His widow and a son and daughter survive him.  
A. F. T.

W. A. YOUNG, M.B., Ch.B., D.P.H., D.T.M.,  
Director, Medical Research Institute, Accra, Gold Coast.

In our last issue we had to announce with much regret the death of Dr. W. A. Young at Accra, Gold Coast, on May 30th from yellow fever. It is believed that Dr. Young contracted the disease in the course of a necropsy upon Professor Noguchi, who died of yellow fever on May 21st.

William Alexander Young was born on November 5th, 1889, at Stnford Hill. He was educated at Forfar Academy and University College, Dundee, graduating M.B., Ch.B. St. Andrews in 1911. Like many another of his race Young was of "those adventurous souls who look beyond the ridges where the strange roads go down"; after a period of service as house-surgeon at the Royal Halifax Infirmary and a course of instruction in tropical medicine at the Liverpool School, he joined the West African Medical Staff in 1913, and was stationed in Sierra Leone. As a lieutenant in the R.A.M.C. he served with the Expeditionary Force in the Cameroons campaign in 1915-16. In September, 1920, he was transferred to Nigeria on appointment as assistant bacteriologist at the Medical Research Institute. From June to December, 1923, he was attached to the Nigerian Tsetse Investigation Staff, and was then transferred to the Gold Coast on appointment as pathologist. In September, 1924, he became director of the Medical Research Institute at Accra.

Young's bent was towards investigation, and early in his career in West Africa he undertook studies in the fascinating problems of diseases endemic in that region. Trypanosomiasis, blackwater fever, and yellow fever each in turn engaged his attention, and by careful and painstaking work in the laboratory and in the field he added something to our knowledge of each of them. Incidentally he found time for the study of interesting pathological conditions encountered in the course of routine work, and from 1923 to 1926 he contributed a number of short papers on these subjects to the *Transactions of the Royal Society of Tropical Medicine and Hygiene*. His main scientific interest was, however, in the disease yellow fever, in the investigation of which he lost his life. In 1922 he reported on a small outbreak of yellow fever which occurred at Warri, Nigeria, in October and November of that year. Thence onwards in annual and special reports he recorded the results of his studies in the epidemiology and pathology of the disease, and many of his observations are of first-class importance. Professor Noguchi of the Rockefeller Institute for Medical Research worked in the Accra laboratory from November, 1927, until he himself fell a victim to yellow fever. Though maintaining different points of view as to the causation of the disease, personal relations between Noguchi and Young appear to have been singularly happy.

Young was a cautious and kindly man, and as stern a critic of his own work as he was of that of others. Nothing did he set down in malice. Throughout his career in West Africa he worthily upheld the great traditions of British medicine in the tropics, and fell at last a martyr to his high sense of duty. Much was expected of him, and the service he loved and adorned is greatly the poorer for his loss. In a letter received in London only a few weeks ago Young discussed his own recent observations on the infectivity of post-mortem material in experimental work on yellow fever. He was therefore well aware of the grave risk he ran in performing a necropsy upon his colleague, and it is not to be doubted that so careful a man took every precaution to avoid infection. He failed, and so another name is added to the roll of laboratory workers who have lost their lives in the study of yellow fever in West Africa. But the

fruits of their labours and of those of other workers in the same field are seen already in the record of a notable advance in our knowledge of yellow fever prevention which appears elsewhere in this issue of the *British Medical Journal*.

Dr. JOSEPH THOMPSON CARSON, who died at Dover on May 30th, was born in Ulster in 1885, and received his medical education at the University of Edinburgh, graduating M.B., Ch.B. in 1908. He was admitted F.R.C.S.Ed. in 1922. After qualifying he held resident surgical posts at Bolton Infirmary, at the Ingham Infirmary, South Shields, and at the Borough Infirmary, Birkenhead, and subsequently commenced practice at Oldham. Soon after the outbreak of war, in 1915, he received a commission in the R.A.M.C., and was appointed radiologist to a general hospital in Salonika, where he served until 1918. He was awarded the fifth class of the Serbian Order of St. Sava for his work in that theatre of operations. After the war he returned to Oldham, but some years later removed to Dover, where he was latterly honorary surgeon to the Dover Hospital. The illness which caused his death was recognized as hopeless two years ago, but notwithstanding his knowledge of this fact he continued at work to the last. Dr. Carson, who was a member of the British Medical Association throughout the greater part of his professional life, is survived by his widow.

The following well-known foreign medical practitioners have recently died: Professor ALBERT PITRES, honorary dean of the faculty of medicine of Bordeaux and national associate of the Académie de Médecine; Dr. EMILE ALEXANDRE LENOIR of Brest, corresponding member of the Académie de Médecine; Professor WALTHER KAUSCH, aged 62, director of the surgical department of the Augusta Viktoria Hospital, Berlin; Professor BERNHARD POLLAK, a Berlin ophthalmologist, aged 63; Dr. LUIZ VIEIRA, professor of criminal anthropology and psychology in the Oporto faculty of medicine, and author of several works on dermatology and syphilis; Dr. RICARDO BOTEX, professor of the Catalan Society of Otorhinolaryngology; Dr. BERNARD HEINE, professor of otology at Munich; Dr. VINCENZO PATELLA, formerly director of the medical clinic at Sienna, and an authority on cardio-vascular disease, aged 75; Dr. DON PEDRO SAINT LOPEZ, editor of the *Voz Medica* of Madrid, and Dr. LAMBERTUS THEODORUS VAN KLEEF of Maastricht, a prominent Dutch surgeon, aged 82.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons reassembled on June 5th after the Whitsun Recess. The Finance Bill was read a second time that day, and on the following days the Rating and Valuation (Ascertainment) Bill was discussed. On June 5th the Rag Flock Act (1911) Amendment Bill was read a second time.

### *Silicosis and Workmen's Compensation.*

Sir W. JOYNSON-HICKS told Mr. Jenkins that no compensation was payable at present to workmen who contracted silicosis in the coal-mining industry, but he had asked the Departmental Committee on Workmen's Compensation for Silicosis to advise on the terms of a scheme under Section 47 of the Workmen's Compensation Act for the industry, and for this purpose he had appointed to the committee representatives of each side, nominated by the Mining Association and the Miners' Federation respectively.

Mr. D. GRENfell asked when the Home Secretary expected a report from the committee. Sir W. JOYNSON-HICKS said that it was only on May 3rd that he informed the House that he had not got the names of the representatives from one of the associations. He had now got them, and had appointed them. He believed they were getting to work at once. Mr. RENNIE SMITH asked if the Home Secretary had powers to give compensation for silicosis in the interim. Sir W. JOYNSON-HICKS said that he had no such powers. Mr. KELLY asked if the terms of reference to the committee dealt with districts other than South Wales. Sir W. JOYNSON-HICKS: Yes, certainly.

Commodore KING informed Mr. Jenkins that the inquiries which had been made as to the occurrence of silicosis among miners working in hard rock in coal mines had included analyses and other tests of the rock dust.

**Manufacture of Cocaine in England.**—On June 5th Sir P. CUNLIFFE-LISTER told Mr. Fenby that the manufacture of cocaine and cocaine hydrochloride in substantial quantities had been carried on in this country for some time under the authority of the Home Office. He understood that these materials would shortly be available for disposal, and the conditions for exemption from duty were, therefore, not satisfied.

**Adulteration of Milk.**—On June 5th Sir KINGSLEY WOOD, in reply to Sir Walter de Frece, said that official statistics indicated a progressive decrease in the adulteration of milk, the percentage of samples reported by public analysts as adulterated or below the presumptive standards being 6.9 in 1927, as compared with 7.4 in 1926, and 9.3 in 1920. There was no specific requirement as to the number of samples to be taken annually by a local authority, but it was the practice of the Ministry of Health to communicate from time to time with those authorities which did not seem to be taking a sufficient number to provide a proper check on adulteration.

**Manufacture of Sheep Dip.**—Sir W. JOYNSON-HICKS, on June 5th, informed Mr. W. Thorne that he was advised that the processes of the manufacture of sheep-dip were liable to give rise to diseases of the skin but the number of such cases reported in the last few years had been quite small. The Factory Department had not been able to trace any recent cases of a serious character at the Barking Creek factory, and it was presumed that cases to which Mr. Thorne referred in his question had occurred some years ago. The main precautions to be taken were the provision of adequate exhaust ventilation and suitable washing facilities, but these could be already secured in all cases where arsenic was used under the existing provisions of the Factory Act, and he was advised that no additional regulations were necessary.

#### Notes in Brief.

Officers of the Ministry of Health are in consultation with local authorities about the improvement of the administration in the casual wards at Thame.

Statistics showing the total sum paid in rates during the last two years by hospitals in England and Wales are not available.

## Medical News.

THE new surgical block of the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E., will be opened by H.R.H. the Duke of Connaught on Tuesday, June 12th, at 3 o'clock. The guests will be received afterwards in the grounds by the Lady Mayoress.

As previously announced, the opening ceremony of the Samuel Augustine Courtauld Institute of Biochemistry, Middlesex Hospital, will be held at 3.30 p.m., on Thursday, June 14th; Sir Archibald Garrod will deliver an address entitled "The place of Biochemistry in Medicine." Old Middlesex students will be welcome on presentation of their cards.

THE prize-giving ceremony at the London Hospital Medical College will be held in the library on Friday, June 29th, at 3 o'clock. After the prizes and certificates have been distributed by the Rt. Hon. Sir Samuel Hoare, Bt., Secretary of State and President of the Air Council, there will be tea and music in the hospital gardens.

THE annual dinner of the Harvelian Society of London will be held at the Connaught Rooms, Great Queen Street, on Thursday, June 14th, at 8 p.m.

THE annual general meeting of the London and Counties Medical Protection Society will be held at Victory House, Leicester Square, W.C., on Wednesday, June 13th, at 4 p.m.

A MEETING of the Biochemical Society will be held at the Rothamsted Experimental Station, Harpenden, to-day (Saturday, June 9th). An inspection of the experimental fields will be made in the morning and the meeting for business and communications will be held in the Sample House at 2.15 p.m. The papers will include one on the action of  $\alpha$ -radiation on vitamin D in irradiated ergosterol, by R. R. Morrison, P. R. Peacock, and S. Wright.

AN exhibition of old sporting pictures is being held this month in aid of the Royal Free Hospital at Messrs. Knoedler's galleries, 15, Old Bond Street.

THE second international conference on light and heat in medicine, surgery, and public health will be held in London from October 29th to November 1st, 1928, at the University of London, South Kensington, S.W.1. It is hoped to arrange visits to representative clinics, and an exhibition of apparatus and accessories for ultra-violet light, radiant heat, and University. The conference will be held in the Great Hall of the British Buildings, 1.

medical practitioner on request.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on Monday, June 11th, at 10 a.m., Mr. Lane-Roberts will give a clinical demonstration in

gynaecology at the Royal Northern Hospital, and on the same day, at 3 p.m., Mr. MacCallan will demonstrate at the Royal Eye Hospital, while on Tuesday, June 12th, at 2 p.m., Dr. Anthony Foiling will give a clinical demonstration at the Hospital for Epilepsy and Paralysis, Maida Vale, W.9. Two special courses, each lasting two weeks, begin on June 18th—at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E., and the Obolson Hospital for Women. There will be a general practitioner's course at the London Temperance Hospital from June 18th to June 30th from 4.30 to 6 p.m., and a course at the West End Hospital for Nervous Diseases from June 25th to July 21st, consisting of clinical demonstrations on selected cases. Information regarding the general course of instruction and copies of all syllabuses may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A NEW post-graduate course in genito-urinary diseases at St. Paul's Hospital, Endell Street, W.C.2, opened on June 7th. On June 13th Mr. R. H. Jocelyn Swan will lecture on the treatment of enlarged prostate. The lectures will be continued weekly and will terminate on July 26th, when Sir Thomas Carey Evans will discuss stone in the bladder with special reference to treatment by litholapaxy. Cystoscopic examinations are conducted daily with the exception of Tuesday and Saturday, and urothoroscopic examination daily except Saturday. Operations are performed on Mondays, Wednesdays, Thursdays, and Fridays at 2 p.m. The course is free to medical practitioners and students, who can attend any branch of the work in which they are interested. Tea is served at 4 o'clock before each lecture.

A POST-GRADUATE lecture demonstration on physiotherapy will be given by Dr. M. B. Ray, honorary secretary of the British Committee on Rheumatism, of the International Society of Medical Hydrology, at the Epworth Street Medical Baths, Boverly Road, Hull, on Friday, June 15th, at 8 p.m. All medical practitioners in the district are invited.

A POST-GRADUATE course on new developments in pediatrics will be held in Paris at the Hôpital des Enfants Malades from July 26th to August 2nd inclusive. Further information may be obtained from the Secretary of the Faculty of Medicine, 149, Rue de Sévres, Paris XV.

A POST-GRADUATE course in the diagnosis and treatment of cancer will be held at the Cancer Institute in Paris; from July 2nd to the 13th, under the direction of Professor G. Roussy. The course will include lectures and laboratory demonstrations; and, in connexion with it, a diploma will be awarded by the Faculty of Medicine. Further information may be obtained from Mlle Hure, Salle Bédard, 12, Rue de l'École de Médecine, Paris VI.

A COMPREHENSIVE post-graduate course in oto-rhino-laryngology will be held, under the direction of Professor G. Canu, at Strassbourg, from July 16th to 28th. Further information may be obtained from Professor Canu, 1, Place de l'Hôpital, Strassbourg. From October 8th to 25th there will also be a course at Strassbourg in tuberculosis and the diseases of the respiratory passages. Further details may be obtained from Dr. Vaucher, 8, quai Finkwiller, Strassbourg.

AN international conference on the physical, biological, and therapeutic aspects of light will be held at Lausanne from September 10th to the 12th, and the following day will be spent at Loysin. The subjects to be dealt with include a lecture on the therapeutic, prophylactic, and social aspects of heliotherapy, by Dr. Rollier; heliotherapy in Belgium; radiation of food; a lecture on the sun and artificial light, by Professor Leonard Hill; and pigmentation caused by light. Dr. G. Murray Levick is the general honorary secretary in England, but inquiries should be addressed to the Secrétariat Général de la Première Conférence Internationale de la Lumière, Lausanne, Switzerland.

THE president of the Royal Free Hospital, Lord Riddell, and the treasurer, Mr. Albert Levy, have undertaken to give in equal shares the sum of £100,000 necessary to secure the promised gift from Mr. George Eastman, of the Kodak Company, of £200,000 for the new dental clinic which, it is expected, will be completed within the next two years. With this provision assured for the dental clinic efforts will now be concentrated on raising the sum of £150,000 needed for other developments, such as the rebuilding of the pathological and maternity departments.

THE Scottish Board of Health has reappointed the Scottish Advisory Committee on the Welfare of the Blind for a further term of office. The medical member is Dr. George MacLay.

THE Minister of Health has forwarded to county councils and local sanitary authorities in England lists of the statutory rules and orders relating to the new amending regulations in connexion with the notification of puerperal pyrexia and ophthalmia neonatorum, which come into operation on July 1st next, from which date the procedure in regard to these notifications will be the same as that in force for the notification of cases of puerperal fever.

When the original appeal for a memorial to the late Earl Haig was raised it was intended that the fund should be utilized to erect and endow Douglas Haig Memorial Homes in various parts of the country for ex-service men and their dependants. The trustees have, however, found that the demand for accommodation will prove more extensive and varied than was anticipated, and they have therefore decided to reserve the right to earmark a proportion of all future subscriptions for the provision of a fund, the interest of which will be utilized to assist ex-service men with housing accommodation other than in the Haig Memorial Homes.

Dr. W. JAMES SUSMAN of Henley-on-Thames has been appointed deputy coroner for South Oxfordshire.

The mayor of Widnes, on May 29th, unveiled a memorial erected by public subscription among the people of that town to honour the memory of the late Dr. Croighton Hutchinson, who died on that date last year after over forty years in practice in Widnes. The memorial consists of a granite pillar surmounted by a bronze bust of Dr. Hutchinson, and is situated in the Victoria Gardens. Among those present at the unveiling ceremony were his brother, Dr. John Hutchinson, his nephew, Dr. C. H. Lindsay, and many representatives of public bodies and of the medical profession. The late Dr. Croighton Hutchinson received his medical education at the University of Glasgow; he obtained the diploma L.R.C.S. Edin. in 1882, graduated M.B., C.M. Glasg. a year later, and proceeded M.D. in 1889. Practically the whole of his professional life was spent in Widnes, where he enjoyed the respect and affection of all classes. He was particularly devoted to children, and was a popular figure among them to the last. He had been a member of the British Medical Association for over forty years, and was at one time vice-chairman of the Warrington Division; he had also held office as president of the Widnes Medical Society.

The 21st Voyage d'Études Médicales, the well-known series of medical tours to French health resorts, will take place from September 1st to September 12th this year in the Auvergne and Bourbonnais districts. The party will assemble at Pougues and will proceed thence by daily stages with visits to centres of medical interest to the dispersal point at Vichy. Membership is confined to practitioners and to students who are completing their medical studies. The inclusive cost of the tour will be 1,100 francs (about £9) from Pougues to Vichy, and cheap fares will be available between frontier stations and these points. Further information may be obtained from Madame Juppé-Blaiss, Federation of the Health Resorts of France, 1, Gordon Square, W.C.1.

The *Bulletin of the Ophthalmological Society of Egypt* for 1927 contains the proceedings of the society during its twenty-fourth year, with an index of all the proceeding volumes. Several clinical articles in this issue are illustrated by coloured plates.

We have received the first issue of *Dermatologia*, a well-illustrated Hungarian journal of cutaneous diseases published monthly at Budapest under the editorship of Dr. Jakab Justus. The original articles, of which abstracts are given in English, French, German, and Italian, are by Professor L. Nékán of Budapest, on the social work of the venereologist; Dr. L. Brocq of Paris, on the general conception of the dermatoses; and by the editor, on precancerous conditions of the skin and adjacent mucous membranes.

The *English Review*, which has been for several years past a consistently good shilling's worth, maintains its reputation this month by publishing the full text of Sir Arthur Keith's very interesting lecture entitled "Implications of Darwinism," which he gave on May 9th to the University of Manchester, and of which garbled accounts appeared at the time in some newspapers.

In connexion with the International Congress of Oto-rhino-laryngology, to be held at Copenhagen from July 20th to August 1st, of which details were given last week (p. 955), we are asked to state that, owing to the number of papers, each speaker will be limited to seven minutes, and to remind those attending that the subscriptions to the congress, 30 Danish kroner and 15 kroner additional for each member of a family, should be sent to the treasurer, Dr. Jorgen Moller, 13, Vestro Boulevard, Copenhagen, K.

The first meeting of the committee appointed by the Minister of Health to consider the working of the Midwives Acts, 1902-1926, with particular reference to the training of midwives (including its relation to the education of medical students in midwifery) and the conditions under which midwives are employed, took place on June 5th, under the chairmanship of Sir Robert Bolam. It was decided that the meetings of the committee should be held in private, but that communications giving brief details of the meetings should be issued for the information of the press from time to time.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863**, and **9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:  
**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Aitology Westcent, London.*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY**, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

## QUERIES AND ANSWERS.

### MIGRAINE.

Dr. E. J. DREK (London, W.) writes: In reply to the inquiry of "M.R.C.S." about migraine (June 2nd, p. 956), I suffered from intense migraine for many years, and found it due to "tea sensitization." I gave up drinking tea altogether, and have been free from migraine ever since, nearly twenty years. In the course of my practice I have discovered quite a number of patients similarly sensitive; they also have been cured by becoming "tea" total abstainers. I offer the suggestion for what it is worth.

### ULTRA-VIOLET RAYS FOR ACNE.

Dr. H. HALDIN-DAVIS (London) writes in reply to Dr. Gnthrio's inquiry (June 2nd, p. 956): I do not think that a case such as Dr. Gnthrio indicates will benefit more from the intensified treatment with the Kromayer lamp than from a course of exposures to a mercury vapour lamp at a distance of about three feet. But the sort of acne which is most benefited by such local treatment is that in which the pustules are quite superficial. In the indurated cases additional help may be obtained from generalized irradiation of a considerable portion of the cutaneous surface with a view to raising the bactericidal power of the blood. Caution must be exercised in attempting this, as an excessive dose may cause a diminution of the bactericidal power of the blood, instead of an augmentation. Consequently only about a quarter of the whole cutaneous surface should be exposed for about half a minute at the first sitting, and the dose only increased slowly subsequently.

### MEDICAL FACILITIES ON MOHAMMEDAN PILGRIM SHIPS.

Dr. R. A. D. POPP (Chester) writes: With regard to the letter of "Port Said" (May 26th, p. 930), I can only think that he has been exceedingly unlucky in his ship. During eighteen months' sea experience four years ago I saw a fair amount of the Mohammedan pilgrim trade from the East Indies and Straits to happen that I have only actually been westward-bound. Much depends on the ship's personnel, but in my experience pilgrims were always exceedingly well treated by the ship's officers. The captain and officers of my last ship were presented with an address of gratitude on our arrival at Jeddah. Sick comforts have always been available on request, so far as the chief steward's resources would allow. They included whisky, brandy, milk (tinned), various farinaceous foods, and meat extracts, if desired. Sickness and the death rate are largely dependent on the time of year and direction of pilgrimage. Westward-bound pilgrims are always healthy, as they are subjected to medical inspection on embarkation, and at the most suffer only from minor ailments. Pilgrims returning home from Mecca, on the other hand, have been weakened by weeks of religious festivals and desert travelling and starvation, and have generally been herded in pilgrim camps at Jeddah for some time before embarkation. They are usually very emaciated, and various diseases, such as dysentery and small-pox, may be incubating. Consequently their sickness and death rates on the homeward voyage are high; a fairly average death rate in such a people would lie between 10 and 20 per 1,000. With regard to this, it is interesting to note that it is the pilgrim's greatest wish to die while on his pilgrimage, if die he must, and various ship surgeons I have met consider it impossible to avoid most of these deaths on this account.

## "VITA" GLASS.

Mr. R. R. BYRNE (Director, "Vita" Glass Marketing Board, London) writes: The assertion quoted in the *British Medical Journal* (May 19th, p. 884) by Dr. Colquhoun to the effect that after being subjected to the sun's rays for some time "vita" glass becomes discoloured and impermeable to the ultra-violet light, when "vita" glass is exposed to the sun's

at a point where the amount transmitted is small, matter how much longer the glass is exposed. This point of so-called "solarization" can be reached much quicker by exposure to artificial sunlight lamps, which are very rich in the ultra-violet. Under these circumstances "vita" glass reaches a stable condition within two hours, and further exposure has no effect. Even when completely solarized it still transmits a large percentage of those rays in the therapeutic zone of the ultra-violet rays in sunlight to which ordinary glass is completely opaque. This matter has been fully investigated by the Bureau of Standards in the United States, and all their results confirm the above statement, as set out in their letter circular 235 (Third Revision) of January 14th, 1928.

\* \* An article on this subject, by Dr. H. E. MacDermot, appears in the *Canadian Medical Association Journal* for May, 1928.

## INCOME TAX.

## Wife Commences Practice.

"M. N. O." is a whole-time public official and has recently married a medical woman. If his wife practices and uses the car and a portion of the residence, can deductions be claimed, and how should the statutory return be made if the professional expenses exceed the gross income?

\* \* Deductions can be claimed so far as reasonable—for example, "M. N. O." might have to fall back on an estimate of mileage cost for the use of car; if the amount of professional work is small he may have to take into account the assumption that the usual proportion of rent, etc.—for example, one-half—will not be allowed. The cash basis of calculating receipts will not be permissible in the first two or three years. The wife's income should be stated separately, and the special personal deduction of £45 will be due in making any charge to tax. If losses are incurred they can be carried forward to set against future profits.

## Purchase of Partnership Share.

"Y. Z." purchased, as from January 1st, 1928, a half share in a single-handed practice. On what basis is he assessable for 1928-29, and if out of that of the 1927 profits, can he claim any special allowance, seeing that no bills were sent out for the first six months of the partnership?

\* \* The basis of assessment of the firm is the amount of the profits of the practice for 1927, and "Y. Z." will be liable to account for tax on one-half of that assessment, less the usual allowances. If the profits of the practice should fall short in 1928 from some specific cause, the firm can claim some special relief, but presumably this is unlikely to happen. The fact that, so far as "Y. Z." is concerned, the cash receipts will fall short of his share of the assessment furnishes no ground for relief.

## Expense of Assistant's Board, etc.

"O. B. T." states that the local inspector of taxes has hitherto allowed £144 per annum as representing the cost of the board and lodging of his assistant, but now declines to allow more than £70.

\* \* We are not aware of any general regulation or agreement on this matter—indeed, circumstances must vary so widely between different practices that any fixed allowance seems impracticable. The only reply we can give to "O. B. T." is the not very helpful one that which of the amounts is nearer the truth must depend on circumstances not within our knowledge—for example, the general house expenses, standard of living, etc. One point that may have been overlooked is that part of the cost of the domestic staff is allocable to the assistant's accommodation.

## LETTERS, NOTES, ETC.

## OPHTHALMIC PROPHYLAXIS AND TREATMENT IN PALESTINE.

Dr. N. A. HAMZEH (Dublin) writes: There appeared in the *British Medical Journal* of May 19th (p. 865) reference to a paper by Dr. Ticho (not Tricho) at the meeting of the Academy of Medicine in Jerusalem on the incidence of ophthalmia in Palestine, in which he emphasized that improved general hygiene, with expert and timely treatment, would prevent blindness in 75 per cent. of cases. As a medical officer of the Department of Health of Palestine, which is doing a great deal of work towards alleviating eye diseases in general, a fact which might have been recalled, I take the opportunity of pointing out very briefly the measures taken by this organization in this respect: (1) The first and most important step is the organized, persistent, and systematic treatment of the eyes of Government school children—and in some places non-Government—by specially trained doctors and nurses. The effect of this work has been very marked and

perceptible. (2) The second step was the establishment, four years ago, of well-equipped ophthalmic clinics, conducted by specially trained medical officers, in all the districts of Palestine, particularly where trachoma and its complications are very prevalent. These clinics have done excellent work, and have really reduced the incidence of blindness as far as possible, thus fulfilling the purpose aimed at by Dr. Ticho in his words—"expert and timely treatment."

\* \* We have referred more than once to the valuable work carried on by the Government in Palestine. For example, mention was made of these ophthalmic clinics in our columns on February 13th, 1926 (p. 295).

## INVERSION OF THE UTERUS.

FOLLOWING the reports in the *Journal* of cases of inversion of the uterus (August 27th, 1927, p. 350; October 1st, p. 595) two further accounts of cases of this condition have been received from abroad.

Dr. L. B. HAYE (Sarawak) writes: In November, 1927, I was called to a young Malay woman, a primipara, of healthy and robust appearance; on my arrival I was told that the child had been born two and a half hours previously, and that labour had lasted in all eight hours. The child was healthy and the native midwife denied having attempted to expel the placenta or pulled on the cord. I found the uterus inverted and protruding from the vagina for some six inches; the cord was still attached to the child and the placenta to the portion of uterus still in the vagina. There was very little haemorrhage; the pulse was weak, but the patient did not appear to be in much pain. After some trouble I persuaded the relations to allow me to give chloroform; I then peeled off the placenta. Very little haemorrhage occurred (1 c.c.m. pituitrin had been given previously). After removing the placenta I replaced the uterus by bimanual manipulation, and inserted a large plug in the vagina. The woman made an uneventful recovery. It is rarely that Malays allow any European interference in childbirth, and the various objections to my treatment did not make the operation any easier. It had to be performed in a native hut, where aseptic conditions are entirely lacking.

Dr. WINIFRED H. (Malay States) writes: A woman, aged 28, having been delivered of a child with a history of a pulse was 140 and the temperature 103° F. The uterus was completely inverted and wrapped in a dirty piece of cloth. The exposed endometrium was swabbed with tincture of iodine, and then the uterus was gradually reinverted by pressure on the fundus; this was completed easily and without an anaesthetic. A hot intruterine douche was given and 20 c.c.m. of antistreptococcal serum injected into the flank. At 6 p.m. the uterus became completely inverted again. It was replaced in the same way, the vagina packed with acrilavine gauze, and morphine gr. 2 given. On the next day it was repacked, 20 c.c.m. of antistreptococcal serum being injected. The packing was removed on the following day; an offensive discharge was present. Iodine on the following day; during the next four days the douches were given twice daily. The patient had an irregular pyrexia, but no malarial parasites were found in the blood. She then had a sudden severe haemorrhage, and large clots were expressed from the uterus. An intruterine douche was given and 1 c.c.m. of pituitrin was injected intramurally. The patient had no more bleeding, but three days later the vagina and cervix were seen to be covered with a yellowish membrane. Treatment with iodine douches was continued for three weeks, when the membrane had completely sloughed away, leaving a healthy-looking vagina and cervix, and the temperature had been normal for fourteen days. The main features of interest about the case (Dr. Mitchell adds) seem to be: (1) the reinversion of the uterus after replacement; (2) the severe haemorrhage on the eighth day. As there were no retained products, it may have been due to secondary haemorrhage.

## A DISCLAIMER.

Mr. VICTOR BONNEY (London, W.) writes: I have seen this morning (June 6th) in the *Daily Express* what purports to be an interview with me reproducing my words. Many of the things reported I did not say; others were said with the distinct understanding that they were private. The message I permitted to be published was the fact, learned from my journey to New Zealand, that closer intercommunication between Medicine in the Motherland and in the Dominions would be of enormous value. Of course, no proof of the intended article was submitted to me.

SUPPORTERS of Empire produce may be glad to know that Messrs. Lambert and Butler have lately put on the market a brand of cigarettes manufactured entirely from Rhodesian Virginia leaf blended at Salisbury, the centre of the tobacco-growing district in that country. These well-made "Rhodian" cigarettes are worth a trial by smokers whose palates are open to new impressions.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 46, 47, 50, 51, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 247.

## A British Medical Association Lecture

ON

## HEART ATTACKS.

DELIVERED TO THE CHELSEA DIVISION, APRIL 25TH, 1928,

BY

CAREY F. COOMBS, M.D., F.R.C.P. LOND.,

PHYSICIAN TO THE BRISTOL GENERAL HOSPITAL.

The diversity of phenomena attributed to cardiac origin will be apparent from the following list of diagnoses collected during the past three months in cases labelled by the patients themselves as heart attacks. First comes the group of troubles not actually connected with the heart at all—gall-stones, epilepsy, aural vertigo, narcolepsy. Secondly, there are disturbances of the heart without evidence of organic disease. Of these there are two chief varieties—premature beats and extracardiac arrhythmia, the latter manifesting itself oftener as speeding, but sometimes as slowing, of the heart. Last of all come the cardiac attacks proper, the symptoms of which are caused by organic disease of the heart. Angina pectoris, cardiac infarction, acute oedema of the lungs, and cardiac asthma all come within this group; so also do most cases of auricular flutter, so far as my own experience has gone.

The predominant symptoms may be roughly divided into two classes—the cardiac and the peripheral. The patient suspects his heart of being the cause of his attacks, either because he feels something amiss in the region in which he believes this organ to lie, or because of symptoms elsewhere which common report has taught him to regard as cardiac in origin. Subjectively considered, these attacks may be discussed under four headings, according to the predominant symptoms.

## 1. PALPITATIONS.

More than a quarter of the patients seen in private practice for cardiac attacks may be classed as suffering from palpitations. It must be remembered, too, that these are more or less selected cases; all had passed through the hands of at least one medical man before seeing me. If we were to consider instead the unsifted experience of an out-patient department or a family practice we should find the proportion of functional cases even higher, for, almost without exception, patients who complain chiefly of palpitations are suffering from functional disorder of the heart's action. One principal reason for this is that when the palpitation is symptomatic of organic heart disease—as, for example, in some patients with auricular fibrillation—there are other symptoms, such as dyspnoea, which more urgently occupy the patient's mind. When palpitation is the chief source of distress it is usually the subjective counterpart of one of two kinds of disturbance of rhythm. In the first place, the heart may be accelerated by extraneous causes operating through the vago-sympathetic apparatus by which its speed is regulated. Often these causes are psychical; and by no means obvious either to the patient or to the doctor. On little or no apparent provocation the heart's speed rises to 120 a minute, and continues at this rate long enough to make the patient acutely uncomfortable. Often, too, the attack is aggravated and prolonged by the fear which it arouses, this in turn helping to maintain and increase the acceleration of the heart's action. Gradually the attack dies away, either under the influence of a reassuring prognosis or spontaneously. If the doctor is there in time it will be noted that the speed rarely exceeds 120 a minute, that it varies a little, and is amenable to such influences as deep breathing and emotion, and that its start and finish are gradual and not abrupt. Frequently, however, these attacks come on in the night, presumably as the result of some disturbance of the subconscious mind, and the onset, if not the whole of the attack, escapes observation. Even so, however, it is nearly always possible to detect in the pulse rate an undue susceptibility to external influences; and the history of the attack, together with the absence of organic disease of the heart, makes the diagnosis simple as a rule. Usually the patient is a young

adult, of nervous temperament; but, though this is a useful guide, it is by no means infallible. I have recently seen an old gentleman within a month of his eightieth birthday whose nocturnal attacks are quite obviously of the variety I have tried to describe; and one of the worst cases I ever saw occurred in a burly farm labourer.

Such cases are, of course, well known, and it may seem that I am laying unnecessary stress on the existence of this syndrome. But it is not always recognized even by the medical man, and even when it is recognized it is by no means always possible to persuade the patient or her relatives that the symptoms do not indicate serious trouble. Particularly in medico-legal cases, where the attacks are supposed to date from some strain, and thereby to entitle the patient to compensation, it is often impossible to get rid of the symptoms.

Other influences beside emotion can quicken the action of the heart by their operation through the vago-sympathetic controls. For example, in the thyrotoxic state palpitation is often an early symptom, but it is usually so persistent that it does not present itself to the patient in the form of an "attack." Once a girl aged 17 was brought to me at the hospital for attacks of palpitation; she had a pulse rate of over 120, which examination proved to be due to widespread tuberculosis of the lungs. Similarly, the Ministry of Pensions found many cases of "D.A.H." due to pulmonary tuberculosis.

The other kind of disorder that gives rise to a complaint of palpitation is the premature beat or extra-systole. When this occurs, as it often does, in periods or bouts, the result can be extraordinarily disquieting. The patient feels a sensation as if his heart gave a kick or turned over; or it may be the pauses that he notices. If this sensation keeps on recurring it may be enough to keep him awake at night. Curiously, it is common among doctors, as Galli has lately observed. When the patient comes for examination the disorder may refuse to exhibit itself; but if you are lucky you will catch at least one or two premature beats, either when the patient lies down or when he stands up again, and by comparing notes with the patient you will find that it is this phenomenon, repeated often enough to accumulate into an attack, which is responsible for his bouts of discomfort. A number of these patients are elderly, and the arteries and myocardium may show traces of wear and tear. In spite of this it is our duty to reassure the patient, and to explain to him that, in the words of Sir James Mackenzie, "these disturbances mean no more than grey hair or a wrinkled skin."

Not infrequently both nervous acceleration and premature beats appear in the same patient. This may make the interpretation a little more difficult, but it is only rarely that a graphic record is indispensable. In either case, when we ourselves are content that these attacks have no serious import, this view must be communicated to the patient, not merely as a negative assurance that there is nothing the matter with his heart, but also as a positive statement attributing his symptoms to a nervous disturbance which he can to some extent discourage. Whenever possible the sources of the disturbances should be ascertained and laid before him. Much good is done not only by abstaining from any prescription of medicine, but also by insisting on the value of exercise as a curative measure. We must not forget how much this did for the relief and cure of "D.A.H." in time of war.

I do not want to convey the impression that an attack of palpitation is never dependent on organic disease. Sometimes a man with a hypertrophied heart, the result, perhaps, of aortic regurgitation, will complain more of the battering at his ribs that he feels when his heart is hastened by exercise than of any other symptom. But this rarely limits itself so neatly in point of time as to constitute an attack. I am thinking rather of those disturbances of rhythm which, arising within the heart itself, cause it to beat unduly fast—I mean paroxysmal tachycardia, auricular flutter, and auricular fibrillation. As I have already remarked, the patient with auricular fibrillation rarely complains of palpitation, because he is at the same time nearly always suffering from dyspnoea due to organic disease of the heart. In rare cases, however, auricular fibrillation appears, like paroxysmal tachycardia,

abruptly and without any obvious background of organic disease, and after running for a brief period disappears as suddenly as it came. Again, as in paroxysmal tachycardia, this may recur from time to time in bouts; or it may be an isolated attack, the origin of which remains for ever unexplained.

Far commoner is the ordinary attack of paroxysmal tachycardia. Here also each attack begins and ends abruptly, the heart passing immediately from its normal speed to one twice as high, and back again to normal in the same way at the end of the paroxysm. Usually the patient can give a clear history of this kind of attack, and it is not difficult to recognize its meaning, especially if the pulse, felt in an attack, shows a regular beat of 140 or over. In many instances there are signs of organic heart disease. Usually the patient can give no reason for the onset of the attacks, which arise as often during rest as after exertion. I recollect the case of a young woman who said that her attacks were brought on by stooping or by jolts—for example, when riding pillion on a motor cycle she had known an attack jerked into being, so to speak, on going over a pothole, and jerked out again by another.

The onset and cessation of auricular flutter are usually less obvious, and whereas the bouts of paroxysmal tachycardia often recur for many years without becoming worse, those of auricular flutter are less frequent, but last longer when they do come. In flutter also the high speed rhythm is often broken into from time to time in such a way as to produce periods of irregularity. But apart from a graphic record it is impossible to be quite sure whether a tachycardial paroxysm is due to flutter or not; and it is often impossible to get a graphic record, especially during an attack. Fortunately, it is not necessary to differentiate immediately between the two. In both the essential things are to recognize that the tachycardia is intracardiac and not extracardiac in origin; to see how far there is a background of organic heart disease to which the muscle fatigue engendered by the rapid beating may add materially and even fatally; and to do all that can be done to bring the attack to an end.

As to the first, note that the speed is nearly always high—140 or more; that it is regular, and uninfluenced by extraneous factors, such as breathing or emotion; and that if the high speed breaks off for a period the rate drops at once to normal. The second aspect, that of prognosis, usually presents itself as a premonition of ventricular failure. The pulse, though otherwise regular, exhibits alternation if it is carefully examined by means of the sphygmomanometer; râles appear at the bases of the lungs, and oedema over the sacrum and round the ankles, as the attack goes on; the heart sounds become weaker, and gallop rhythm may be detected, though the speed is often so great that this is impossible; the pulse pressure becomes very narrow, and the patient is in danger of death. In cases where he has had many attacks he often evolves some plan of treatment for himself. One of the most satisfactory is to give him some carminative—for example, ginger with peppermint, to be sipped in very hot water. Occasionally deep breathing is successful in stopping an attack, or alteration of posture. The other day I saw a man who could stop his attacks by putting his finger well back in his mouth. Compression of the vagus in the neck is recommended; I have tried this often, but without success. If these simple measures fail, the patient—who is often very alarmed and uncomfortable—will demand that something more shall be done. We have then to decide whether to confide in the digitalis group, or to use quinidine in the hope that it will recall the normal rhythm. In this my own experience has accorded with the judgement expressed recently by Parkinson and Bedford.<sup>3</sup> The likelihood of partial success with digitalis or its fellows is greater than that of complete success with quinidine. Moreover, there is a certain risk in giving a muscular depressant like quinidine to a patient whose ventricle, often senile or otherwise degenerate, is becoming exhausted by the high speed. For these reasons I prefer to give digitalis, and to give it in large and repeated doses—for example, half a drachm of the tincture every four hours. Recently, in a man of 59, whose flutter had resisted this treatment, an intravenous dose of onabain (0.5 mg.) reduced the speed from

180 to 100. What often happens is that the regular beat of 160 or so a minute, characteristic of flutter, is converted under digitalis treatment to a totally irregular beat of 120 or so, the flutter being replaced by fibrillation. This, again, may revert to normal, either with or without the use of quinidine.

An attack of flutter is a serious matter. Even if not directly fatal it makes the patient incapable of resisting contemporary stresses; and when it supervenes on gross organic disease of the heart it may prove the last phase of that disease. It is, however, a rare phenomenon, and my last word on this subject of palpitation is that nearly always it is due to functional and not to organic tachycardia. When a patient describes his attack as one of palpitations the probability is that his trouble is functional. This does not exclude the possibility of an organic lesion of the heart coinciding but not otherwise connected with the functional disturbance—a combination that is difficult to handle, because it is hard to get the patient to believe that his sensations are not dangerous.

## 2. FAINTING AND GIDDINESS.

Deeply rooted in the public mind lies a belief in the cardiac origin of fainting attacks. It is, I suppose, a diluted edition of that other belief—that the possessor of a diseased heart is necessarily in imminent danger of sudden death. If we could dissipate these two misbeliefs many people would be delivered from a bondage of baseless fear which holds them in thrall. As a matter of clinical experience, how many can recollect any case of organic disease of the heart that revealed itself in the form of fainting attacks? I will speak of two or three examples presently, but first let me ask, How many times has there been found evidence of cardiac disease in a patient troubled by repeated faints? I see many patients who think they have heart disease because they are subject to attacks of fainting, giddiness, or loss of consciousness. Among my notes of these I can discern three principal groups. First among them comes epilepsy. I imagine we have all met the parent who is naturally and properly alarmed at the lapses of consciousness from which her child suffers, and is afraid lest they betoken the presence of a diseased heart. Usually the truth is told her by the first medical man who sees the child; but occasionally some unimportant murmur or irregularity of the pulse is noted and an indecisive reply offered to the inevitable question about the state of the heart. If it were remembered that loss of consciousness is practically never a symptom of cardiac disease in childhood this mistake would be avoided.

A second kind of attack which is very naturally, though erroneously, interpreted as cardiac in origin is the vertiginous syndrome of labyrinthine origin, often spoken of as Ménière's disease. It is a mistake which is easily made, because the giddiness which is the essential feature of the syndrome is often obscured by the faintness and collapse which accompany it; and also because this state of uncertainty as to equilibrium tends to breed a neurasthenic condition one symptom of which is palpitation of the nervous kind described above. That the whole thing is aural in origin is nearly always made clear by the discovery of deafness with a history of tinnitus, and by the recollection that circulatory failure cannot deprive a patient of the balancing function without also depriving him of consciousness.

There is a third kind of fainting attack, which is of great interest, especially in connexion with the present subject, because it is in part due to disorder of the heart's action. Sometimes the patient appears actually to lose consciousness, more often it is a passing bout of faintness which may be associated with abnormal cardiac sensations. The two factors responsible for production of these attacks are a slow pulse and a low blood pressure. For example, one young lady exhibited a pulse rate varying from 48 to 60, with moments of rather abrupt change from the quickened to the slower rate, the systolic blood pressure being 110 mm. of mercury, and the diastolic 70 mm. A sudden change from the recumbent to the standing posture may provoke this kind of attack, and recently Ghrist and Brown<sup>4</sup> have recorded some remarkable falls in blood pressure with such changes in posture which may help to

explain these attacks. Cotton and Lewis<sup>1</sup> furnished the clearest possible evidence that fainting attacks may be directly caused by the coincidence of these two factors in varying proportions. A knowledge of this fact may be of great value in enabling us to furnish a reassuring explanation of attacks which are very alarming to those who witness them as well as to the subject himself.

Sudden faintness and giddiness may also overtake elderly men, as in two cases recently seen.

The one, a business man of 73, but young for his years and full of zest for work, complained that of late his sleep had been poor and that he had been subject to sudden attacks of giddiness, which threatened him with loss of consciousness. It was only momentary and left him none the worse, but as he was driving a car a good deal he was rather perturbed about it. His heart was a little enlarged, his arteries palpable and tortuous, but his blood pressure was only 140 mm. Hg systolic and 80 mm. diastolic. The most noteworthy point was that the pulse, already habitually slow—averaging 54 a minute—was also interrupted by numerous premature beats with compensatory pauses. I think it is probable that these, occasionally reducing his effective beats to 27 a minute, caused a temporary cerebral ischaemia and were thus responsible for the giddy turns.

The other patient, aged 71, appeared to me to owe his attacks to the coincidence of a very low diastolic pressure—only 50 mm. Hg—with a degenerate arterial tree. He not only became giddy, but on more than one occasion actually lost consciousness for a few moments.

It has seemed to me that this faintness is more likely to happen when the blood is in the splanchnic area, after a meal, and to be immediately precipitated by some change of posture, such as rising quickly from an armchair.

In all these rather unusual cases we can formulate some theory to explain the failure of cerebral circulation; either through loss of arterial drive or through gaps in the heart's rhythm, or through a combination of both, a passing moment of ischaemia shows itself in dizziness or even actual loss of consciousness. But how are we to explain such a case as this?

A man of 43, on the stout side and giving a history of malaria and dysentery, but otherwise in good health, was sitting up into one night talking to his friends when he was seized with a sudden convulsive attack, in which he became cyanosed and then comatose. He was seen in the attack by a very accurate clinical observer, who noted the total arrhythmia of auricular fibrillation. Next morning, when he had otherwise quite recovered, this irregularity was still present, though the speed was only 76 a minute (perhaps owing to a dose of digitalin which had been given the night before). The next day again, however, the rhythm had become normal, there were no physical signs of disease, and the following day he exhibited a normal electro-cardiogram.

I am not going to attempt any explanation of this remarkable story, but will pass to a consideration of the Stokes-Adams syndrome. Even here there is room for speculation and diversity of opinion as to the precise reason why the losses of consciousness that mark this condition should occur at the moments when they do. Still, there is no room for doubt about the broad facts. The patient has a slow pulse, thanks to the failure of his auriculo-ventricular connexions, and that slowing of the pulse deprives the brain of its necessary blood, with the result that there are brief periods of complete unconsciousness. If you have ever watched these attacks you will agree that the sequence is very striking. The patient is talking naturally when his face turns pale, his talk stops, and he falls asleep for a second or two. His face flushes and he comes back to consciousness, obviously distressed and apprehensive. This apprehension may defeat its own ends, for I have known it provoke a doctor into dismissing the whole thing as an attack of "nerves" demanding no other therapeutic measure than rousing advice. In this instance, as in some others, the condition was sensibly alleviated, though not abolished, by atropine, which lifts the inhibitory action of the vagus off the auriculo-ventricular connexions, and may thus save the staggering camel from a broken back.

On the whole, however, it is safe to say that when a patient states that he is afraid he has a bad heart because he is troubled by faint or giddy turns, he may be reassured by some explanation of his attacks less menacing than that which his fears have suggested.

### 3. PAIN.

Dr. J. A. Ryle, in his timely address<sup>2</sup> on the clinical study of pain, pleads for a more respectful consideration of the patient's description of his sensations, especially in

view of the limitations of physical diagnosis. Nowhere is this better exemplified than in the realm of cardiac disease. Often the patient's account of his attacks renders it certain that they are due to organic disease of the heart, whatever the results of physical examination. By way of example, let me quote the words in which a man approaching 60 years of age recently described to me the attacks which he had experienced for some six months.

After telling me how regularly these attacks occurred at certain moments in his day—for example, after walking sixty yards from the point at which he nights from the bus that brings him home from business—and adding that at first he thought it was indigestion, because exertion directly after a meal brought it on, he went on to say that the onset of the attack was accompanied by the sensations associated with painful emotion—for example, the reception of bad news. "I know when it is coming," he told me. "I have a sort of uncomfortable feeling as if something were growing in my chest, or as if something were suppressed there. It makes me go slow, and I have to take short steps. If I do this it gets no worse; but if I were to hurry—I couldn't hurry!—a very violent pain comes on here" (pointing to the inner end of the third and fourth left interspaces) "like neuralgia. It makes me break out into a sweat. There may be a tingling sensation, not severe, down the left arm. It is gradually relieved if I stand still." He added that these sensations were not accompanied by nausea or faintness, and that he did not think any onlooker would guess that anything was amiss with him. Examination discovered little beyond a soft systolic murmur at the apex, the sounds being rather weak. His blood pressure was 165/75, and his vessels were normal to touch, though the retinal arteries were distinctly tortuous. The urine was normal.

Now that is a common kind of attack. It is customary to think of it as analogous with the painful limp that sometimes reveals the presence of sclerotic changes in the crural vessels, and on this analogy the syndrome has been labelled "ischaemia cordis intermittens" (Bischoff), and ascribed, on adequate grounds in my opinion, to coronary sclerosis. It is well to explain to its victim that Nature has set a limit to his activities, and has been considerate enough to provide him with an automatic check to prevent him from attempting indiscretions. Caffeine or diuretin, with or without a small dose of potassium iodide, will nearly always decrease the liability to these attacks. For the immediate relief of the pain there is nothing like the nitrites. Nitroglycerin is, I believe, the best of these for habitual use. The liquid form is more active than the tabella, especially if a dose of not less than 5 minims be given in combination with carminatives, such as capsicum and cardamoms. Persons with this degree of pain may enjoy a fair measure of activity for years if only they will recognize the inexorable nature of the limitation imposed on them. When it is associated—as so often it is—with a high arterial tension, great relief is often afforded by a relatively small decrease in pressure, such as may be secured by reduction of diet and stress, with little or no medicinal treatment.

That we do well to pay heed to such a history as this is exemplified by the following case.

A man, first seen at the age of 41, said that for four months he had been troubled by pain in the left chest and arm down to the fingers, coming on with exertion—for example, walking up a slope—and relieved by rest. The pain in the chest was like a pressure. His arteries were thicker than they should have been, and his blood pressure was 180/100 in the left arm, 170/80 in the right. Apart from a ringing accentuation of the aortic second sound I found no abnormal physical signs. His electro-cardiogram appeared normal, the x-ray screen discovered nothing beyond some widening of the aortic shadow, and the Wassermann test was negative. I saw him from time to time, and his doctor and I were gradually convinced of the serious nature of his trouble because we found that no treatment was able sensibly to relieve him. About a year after he was first seen a faint aortic diastolic murmur became audible, and a few months later he died suddenly in an attack of severe pain.

By way of contrast let me give you a brief account of two patients who died in or immediately after their first attacks.

One, a commercial traveller, aged 72, never ill before in his life, was taken ill about 10 a.m. at a country station twenty miles out of Bristol. He was seized with intense gripping pain, which began in the left side of the lower jaw and spread to the left arm and epigastrium. He felt too ill to go on with his journey, and came home. All day the pain persisted, and when we saw him in the evening he looked pale, with bluish lips, and was obviously distressed. His cardiac sounds were weak, and there was a systolic murmur all over the precordium. There was a little oedema over the shins, but the liver was not swollen, nor were râles heard at the bases. His pulse was only 72 and quite regular, and his blood pressure was 150/80. While we were preparing to give him morphine he sank on his knees—we had been unable

to persuade him to lie down—cried out that the pain was unbearable, and pitched over on his face dead. His pulse beat at 72 till it stopped.

The other patient was a clergyman, a very hard-working man of 60, whose doctor was called in eight days before we saw him together, on account of an attack of severe epigastric pain, in which he felt as if he were going to die. The pain was not related to food, but he was heaving wind and vomiting mucus. It all passed off, but the pain recurred once or twice, and in several of the attacks extended into the arms, the right more often than the left. On examination we found nothing indicative of cardiac disease, except that the first sound at the apex was occasionally doubled, but the cardiac nature of the pain was proved by his sudden death a few days later.

All these case-histories emphasize the diagnostic significance of the pain as described by the patient. We must be prepared to recognize the cardiac origin of a pain even when there is little or no objective evidence of cardiac disease to be gained by the most careful examination. At the same time it must be realized that signs of cardiac disease may accompany or follow an attack of pain. As an example of the former I may quote the following case.

A man, aged 37, is now under my care for aortic incompetence of syphilitic origin, on which it is probable that a slow endocardial infection has been engrafted. He has had several attacks of pain coming on without the least provocation, and described by my house-physician, Dr. J. C. Batt, as follows:

"March 22nd, 1928. The patient was lying in bed when he was seized with a pain in the right shoulder. This pain came on when he was lying quietly in bed, and at the time there was no exertion. The patient drew himself upright and was then conscious of a sensation of rapid palpitation over the precordium. The pain in the shoulder was described as knife-like and stabbing, and spread over the precordium and all down the left side as far as the ilium, but no further. During the attack he had an expression of intense agony on his face. The whole affair was relieved in about two minutes by amyl nitrite. Shortly after this the pain, etc., returned with equal severity about twenty minutes after the amyl nitrite had been given, but on repetition of this drug relief was once again afforded, with no return of the pain.

"April 3rd (9.30 p.m.). The patient was sleeping after 'his best day in hospital' when he began to dream that some horses were chasing him. Just as he was about to fall over a cliff to escape them he awoke with violent pain in the precordium. He sat up in bed with a 'pained expression' and placed his right hand over his precordium. This pain radiated to the left shoulder and through to the back of the joint. Throughout the attack there was dyspnoea and the pulse rate went up to 124. The left arm was not moved because the pain was apparently too severe in the shoulder, which during the attack was too tender even to be touched. Amyl nitrite again gave almost instant relief. The whole attack from time of waking lasted about a quarter of an hour. Pain described as like a knife sticking through him."

His electro-cardiogram, taken by Dr. Bruce Perry, shows changes very suggestive of gross disease in the coronary vessels or the myocardium, or both. We think he is less liable to pain when he is taking potassium iodide, and the attacks are partly relieved by amyl nitrite.

Of late much has been written of the syndrome of coronary thrombosis, or cardiac infarction as it is more accurately entitled. This syndrome consists of a severe attack of cardiac pain, often coming on at night, followed in a day or so by evidences of serious damage to the muscular wall of the heart. The patient when seen in or after the attacks of pain looks pale and collapsed, and the pain is obviously intense. Usually it is retrosternal, sometimes behind the xiphisternum, and constricting in character. In some cases there is vomiting, and this, with an epigastric location of pain, may inspire a diagnosis of biliary colic. Either at the time, or within a day or two, the pulse becomes rapid, often alternating, and sometimes irregular, with the total arrhythmia of auricular fibrillation or the hasty action of flutter. If it remains regular a notable fall in systolic pressure is often noted, with a corresponding reduction of the pulse pressure. The heart sounds are found to be weak and antering, and often pericardial friction is heard for a day or two. The temperature also rises for a few days, and there is a leucocytosis. Interesting and characteristic changes in the electro-cardiogram often follow in those who survive, and they have been clearly and convincingly described by Parkinson and Bedford.<sup>7</sup> What is worth insisting on is the value of morphine when the pain is at its height; not only does it give relief, but in some instances it appears actually to save life by diminishing shock. The nitrites, on the other hand, seem to have no effect, which is not surprising when the fall of blood pressure, which has already occurred spontaneously, is taken into account.

What is the connecting link between all these varieties of cardiac pain? To reply fully to this would involve too long an argument. Let it suffice to say that evidence accumulates in favour of the view that pain of this kind depends on interference with the supply of blood through the coronary arteries to the wall of the heart, the severity of the pain varying with the degree of that interference.

I must refer briefly to three terms: pseudo-angina, vasomotor angina, and tobacco angina. The first of these is, I am afraid, a "hedging" form of words. Either a pain is cardiac or it is not. Often, it is true, cardiac pain is exaggerated and its true character obscured by the extravagant accounts of it furnished by imaginative patients. All visceral pain is liable to be thus misrepresented. But the more carefully the history is taken the fewer will be the cases of pseudo-angina. Some of them appear to be due, as Sir Thomas Horder<sup>8</sup> has told us, to spasm of the oesophageal cardia; others are merely attacks of functional palpitation decorated by the patient with an account of pain over what he believes to be the position of his heart. In all cases it is well to say to oneself, "Either this pain is cardiac or it is not, and it is my duty to make up my mind about it."

Vasomotor angina appears in the textbooks, but I must confess that I do not see cases of it. Only one can I recall that appeared to belong to this category, though occasionally there are vasomotor phenomena—acrocyanosis and the like—in patients whose pain is obviously due to cardiac disease.

Tobacco angina is, it appears from the experience of others, an undeniable fact; but in most of the cases so described it seems to me that the tobacco is, at most, only partially responsible.

A professional man consulted me at the age of 55 because of pain behind the sternum, brought on by exertion. I could find no evidence of disease, and some months later he told me that on discontinuing the practice of smoking a pipe as he eyed to his work in the morning he had lost the pain. Two or three years later, however, he told me that he still got the pain if he went out after dinner to meetings. This he attributed to the smoky atmosphere. Once or twice he had runs of tachycardia. I saw him at the tail end of one of these, and it appeared to be a true paroxysmal tachycardia, but I had no opportunity of verifying this by graphic record. Eventually it was proved only too clearly that something more than tobacco was responsible for his attacks, for he dropped dead without warning.

#### 4. DYSPNOEA.

As regards attacks in which dyspnoea is the chief feature I will mention two varieties only—the so-called cardiac asthma, and acute oedema of the lungs.

The term "cardiac asthma" survives merely because no one has invented a more convenient one. It is cardiac, but it is not asthma, unless we decide to include within that word every kind of paroxysm of breathlessness. The circumstances under which the attack occurs are remarkably uniform. Among the last twenty patients seen in private practice for symptoms of this kind all but one have been men, and only one of them under 60 years of age. In every instance the attacks have occurred at night, in two only by day as well as by night. In three-quarters the blood pressure was high, and in several of the others there was reason to think that it had been high and was now reduced only by having brought about ventricular defeat. That, indeed, is the outstanding fact about the clinical picture; it is the clinical picture that is associated with ventricular defeat supervening on long-continued high arterial tension. There is evidence of hypertrophy of the left ventricle, but there is also evidence that in spite of its hypertrophy the ventricle is no longer capable of sustaining an adequate circulation even while the patient is at rest. Consequently oedema is a common symptom. I noted its presence in eleven of these twenty patients. Cardiac pain, on the other hand, is usually absent, or at all events not a prominent feature of the attacks. The heart sounds often betray evidence of ventricular failure in the shape of enfeeblement and gallop rhythm. Six of these patients showed signs of auricular as well as of ventricular failure, the rapid irregular rhythm of the former contributing to the completeness of the latter. In six of the fourteen with a regular rhythm there was alternation of the pulse.

Although this is the fully developed background of these attacks they may nevertheless constitute the first warning of serious disease. It is soon after getting into bed that the patient is conscious of dyspnoea. Often it wakes him out of sleep and keeps him from dropping off again, for as soon as he does so he is seized by the throat, so to speak, and apparently threatened with imminent suffocation, often in the form of terrifying dreams. He cannot lie down in bed; frequently it is impossible even to rest against a bank of pillows, and he has to sit up in an armchair. Sometimes even this does not suffice, and he has tried to find what rest he can by leaning forward with his head pillowed on his arms, on the back of a chair, or on a bed table. Indeed, one of the essentials in treating these attacks is to make provision, by means of one or other of these supports, for such small measure of comfort as is left to the unfortunate victim. I doubt whether there is any more distressing experience that falls to the lot of mankind than this, and it is most tantalizing to be able to offer so little help. Fortunately it is one of the many forms of agony in which the use of morphine brings relief. On the whole I am inclined to think that the value of the morphine is enhanced by combining atropine with it, but about the value of the morphine there can be no doubt whatever. By way of preventing recurrence of the attacks the best remedies to use are, I believe, the xanthine derivatives, particularly caffeine and diuretin. In some instances, when the supervention of fibrillation has precipitated the onset of these nocturnal paroxysms, the use of digitalis may, for a time at all events, decrease the overwhelming load borne by the ventricle and restore the patient to comparative comfort. Otherwise, the chief indication is to reduce the blood pressure by rest, dieting, and purgation, if this has not already been accomplished by the failure of ventricular output.

Acute suffocative oedema of the lungs is rare in my experience. A brief note of a case recently seen with Dr. Paul Bodman, to whom I owe the account of the attack itself, will serve by way of description.

The patient, a high-strung woman aged 60, had for some months experienced pain behind the sternum on exertion, relieved by stopping still. Recently she had also had attacks of dyspnoea at night. In one of these Dr. Bodman found her cyanosed, her face appearing bloated and hot, while the extremities were cold; she was intensely dyspnoeic, with bubbling respiration, and was coughing up blood-stained fluid. Her head felt full, but the veins in the neck were not distended. The blood pressure in the attack was 180/110, whereas at other times it was not so high; yet nitrites gave no relief. One curious fact about the attacks was that they were particularly apt to occur on Saturdays; another, that before the onset of an attack she often felt remarkably well; and also that in the attack there was often an imperative call to relieve the bowels. The attacks seemed to come on when she lay down. She found that in an hour or two the attack passed off, without much help from treatment. We decided to give her a course of diuretin, and this was followed by a relatively long period of freedom from the attacks, which relapsed as soon as the drug was stopped.

Dr. Anthony Birrell, who has lately published an account<sup>1</sup> of some examples of this syndrome, has found that venesection brings relief from the attack. He notes that the blood flows centripetally—that is, from the opening in the vein on the distal side of the incision. This observation may ultimately prove significant in determining the nature of the attacks, the clinical background of which appears to be the same as that of cardiac asthma.

One or two lessons emerge from a study of cardiac attacks. The first is the immense importance of listening to what the patient has to say; after all, he has been through the mill, and may therefore be presumed to know something about it. Even if the attack is obviously functional it is probably the source of much anxiety and distress, for there is something inherent in cardiac sensations of all kinds that appeals vividly to the instinct of fear. Much harm may be done by an unsympathetic attitude towards patients of this class, and it is especially important to avoid even the use of the word "nerves." On the other hand, I believe it is an even worse mistake to frighten the patient whose attacks are really serious by talking to him about sudden death. Usually he is only too well aware of the dangers that threaten him, and it will do more harm than good if the apprehensions that not unnaturally beset him are reinforced rather than allayed.

The patient's age is significant. Attacks due to organic

heart disease are rare in young subjects, while those that are symptomatic of functional disorder are common. Conversely, cardiac attacks arising after 40 are rarely functional in origin. In a majority there is a basis of organic disease, even though this may be overlaid by a superstructure of functional neurosis. It is in cases of this kind that one has to be most careful, especially as the patient's relatives, to say nothing of one's own inclinations, are apt to urge a diagnosis of "nerves." I must confess that I know of no golden rule by which errors of this kind may be avoided, except that which applies to every branch of diagnosis—namely, that of taking trouble over it.

In conclusion, it must be admitted that mistakes are bound to occur, and we must learn to take risks, always bearing in mind that it is the duty of the doctor to consider the safety and well-being of his patient at the expense of his own reputation.

## Observations

ON THE

## VALUE OF RADIOGRAPHY IN THE DIAGNOSIS OF OBSCURE DENTAL SEPSIS.

(With Special Plate.)

BY

JAMES F. BRAILSFORD, M.B.BIRM., M.R.C.S.ENG.,  
QUEEN'S HOSPITAL, BIRMINGHAM.

THE value of radiography in the diagnosis of obscure dental sepsis is now universally recognized. Physicians who, previous to the discovery of x rays, had urged that many of the "rheumatic" group of diseases (arthritis, fibrositis, myositis, neuritis, and certain forms of heart disease) were due to dental sepsis, were faced with the argument that those patients with the most obvious dental sepsis were the patients who suffered least from these diseases. When, however, it became possible to demonstrate on a radiograph deep-seated and unsuspected lesions, the physicians were able to show that these "rheumatic" conditions, which had not shown the slightest response to other forms of treatment, were cured or their progress checked by the removal of the teeth shown to be involved.

Most medical men are familiar with the obstacles which these early workers had to surmount, not only from the members of our own profession, but also from the dental surgeons, who were not prepared to sacrifice useful and "comfortable" teeth without more evidence of their dangerous character.

Patients suffering from dental sepsis may be roughly divided into two groups: (a) those in whom the sepsis is associated with local pain; (b) those in whom the sepsis is unassociated with local pain. The patient belonging to Group (a) usually makes the earliest appointment with the dentist, and in the majority of cases he is able by his clinical examination to detect the seat of the pain. In a few cases, even after a thorough examination, the cause of pain may not be detected, particularly as the patient's localization is so poor, and frequently the pain mysteriously ceases before or while the clinical tests are being applied and cannot be elicited by further testing. This may happen on several occasions. A careful radiographic examination of these cases may reveal the cause in the form of hidden or deep-seated caries, and save the dental surgeon much time and annoyance and the patient much pain. The changes revealed by the radiograph may be obvious or very slight, but even so it may afford the only clue to the site of the pain. It is, however, chiefly with patients in Group (b) that the radiograph is of the greatest value, because the lesion is often unsuspected by the patient, and frequently is not, and apparently cannot be, detected by the most carefully applied clinical tests; and it is not until

the physician or surgeon finds signs or symptoms of a diseased condition which he knows to be generally due to absorption of toxic products from septic teeth that the teeth are radiographed and the lesion demonstrated.

There would appear to be a very great difference of opinion amongst dental surgeons as to the significance of the radiographic findings. It is therefore advisable that the radiographs be interpreted by an unbiased observer. Some still attach no importance to any radiographic appearance, however gross, if the teeth are comfortable and apparently sound; others are prepared to treat lesions which show on the radiographs as dark areas (light areas on the prints made from radiographs as in the accompanying illustrations) of absorption of the periapical tissues, but do not feel justified in "sacrificing" useful and comfortable teeth solely on "slight" radiographic evidence. Experience has now proved that the extraction of such teeth often relieves the symptoms of the patient, and Price states that when such teeth, or cultures therefrom, are inserted into experimental animals the latter die of toxic absorption or infection. On the other hand, some dental surgeons go to the other extreme and extract teeth the best radiographs of which show not the slightest change. Yet Price says:

"I wish to stress that we have come to the time when involved teeth can be so definitely differentiated from those that are not involved or with a sufficient limit of error that we are not justified in condemning all the teeth for fear they may be involved. I am seeing continually patients who are suffering more from the inconvenience and difficulties of mastication and nourishment than they did from the lesion from which their physician or dentist had sought to give them relief."

The important clinical manifestations of hidden dental sepsis were described in 1922 by Dr. Leonard Mackey, whose valuable paper is supported by all the researches which have since been made.

#### THE RADIOGRAPHIC APPEARANCE OF SEPTIC TEETH.

It must be clearly understood that the evidence which the radiograph gives is only a "skeleton" picture of the pathological lesion. The actual lesion, certainly in bone pathology, is always of much greater extent than the radiograph suggests to an untrained observer. Therefore in dental conditions, where the important changes are relatively small in size, it is important to have radiographs which will show these details. Fortunately the close proximity of the radiographic film to the tooth enables a sharp and detailed picture to be obtained which will permit of magnification, and as the danger of the lesion is not to be judged by its size, such magnification will not mislead by showing the slight changes to be definite irregularities.

The outline on the radiograph of a normal tooth enlarged to the size of the radiograph of the femur head is seen to be quite as regular as the latter, whereas the outlines of teeth which show "slight" changes are markedly irregular—a femur head so irregular would be judged to be gravely involved.

Weston A. Price, who with a team of dental surgeons, bacteriologists, and laboratory workers has carried out a very extensive investigation on dental sepsis, considers that 10 per cent. of the teeth with septic roots give no indication of this on the radiograph; but even so, most of the process illustrations which he used in describing the "failure" of the radiographs show definite though "slight" changes, yet process illustrations cannot give the detail of the original radiographs.

There is no doubt in my mind that the figure of 10 per cent. can be considerably reduced by the skill in the radiographic technique and the care exercised in examining and interpreting the radiograph. Further, I am of the opinion that, every tooth which is producing systemic disturbance shows definite changes on the radiograph. The importance of this is apparent when we remember that the clinical tests, even when skillfully employed, may fail to reveal quite extensive lesions.

Burchard and Inglis state that "In cases of granuloma or blind chronic apical abscess there may be no subjective or local symptoms of disturbance cognizable to patient or operator."

A patient suffering from a toxæmia was sent for an x-ray examination of her teeth. She was annoyed at the suggestion that her illness was due to her teeth, and informed me that she paid regular visits to her dental surgeon, who had recently carefully examined the teeth and reported them to be quite sound. (See Fig. 1.)

Price, who has made an exhaustive study of the individual and family clinical histories, clinical, radiographic, and bacteriological examination of the teeth of 681 selected cases in a series of 1,400, has classified patients into three groups. He says that dental infections tend to produce the same type of tissue reaction around the teeth of different members of the same family.

**Group A.**—The radiographs of the teeth of this group of patients show very extensive rarefaction around all the involved teeth, and often extensive pyorrhœa (as in Fig. 2). He regards this local bone absorption as a sign of a good reaction and resistance to the infection on the part of the patients. Such patients, he says, rarely show symptoms of the rheumatic or degenerative disorders, and he accordingly classes them as having "absent susceptibility." Nevertheless, such patients come to hospital complaining of gastro-intestinal or other disorders probably brought about by the septic teeth. Clinically the gums show discharging sinuses, and the teeth are often loose, readily anaesthetized, and easily extracted; the sockets heal with great rapidity and without discomfort or secondary infection.

**Group B.**—In this group of patients the radiographs of the teeth show similar changes to those in Group A, but the periapical areas of rarefaction are bounded by a zone of sclerosed and therefore denser bone (as in Fig. 3). He regards this sclerosed bone as a sign of breaking down of the local resistance to the dental sepsis with the entrance of the septic material into the blood stream. Clinically there are signs of old fistulae and a history of former tenderness. Anaesthesia is less easily produced in patients in this group than in those in Group A. The teeth frequently are difficult to extract, and the sockets do not heal so readily. He says that these patients had acquired a susceptibility to the dental infection, and that, while no rheumatic symptoms were seen when the condition was acute, such symptoms had begun to appear, and they cleared with the removal of the septic teeth.

**Group C.**—The radiographs of the teeth of this group show condensing osteitis around the infected root with little rarefaction (as in Fig. 4). This appearance he regards as a sign of lack of local resistance to the dental sepsis. Clinically there is no evidence of fistulae; the teeth are seldom tender. They appear to be more liable to caries, but are usually free from pyorrhœa. Anaesthesia of such teeth is far from easy, and they are often very difficult to extract. There is great tardiness in healing, and the sockets tend to become infected and painful. Price says that these patients have an inherited susceptibility to the rheumatic group of disease.

This classification tends to explain why some patients with extreme and obvious dental sepsis have often few of the symptoms usually associated with septic absorption, while others with marked rheumatic symptoms have often no obvious dental sepsis, and the radiographs of their teeth show relatively slight changes—so slight that when indicated by the physician or radiologist the dental surgeon is loath to extract the teeth; yet it is often in patients with these "slight" dental lesions that extraction produces marked beneficial effects. As these important indications are relatively slight it is all the more essential that the radiographic technique should be good.

Most physicians will agree that these dental groupings are correct with regard to the susceptibility to rheumatic infections, but few, I think, will agree with the ideas on local resistance.

An examination of the radiographs showing bone sepsis of different types permits of the classification into three groups which resemble those indicated by Price.

**Group (a).**—Patients with bone sepsis due to pyogenic bacteria. The radiographs in these cases show rapid absorption or erosion of the infected bone, and frequently a large amount of pus is found. As the condition of the patient improves and his resistance is increased the rarefied bone increases in density and the patient shows little or no sign of rheumatic disorders, even though the degree of septic absorption, as judged from the patient's condition, was very severe.

**Group (b).**—Patients who formerly showed radiographic changes similar to those in Group (a), but, owing to the separation of sequestra or the inclusion of some septic foreign body, healing is very slow, and the radiograph shows that the

FIG. 1.—Radiograph showing large "cyst" (probably arising from the root-filled bicuspid) which has eroded the apices of the first bicuspid, canine, and central and lateral incisors. Patient had no local physical signs or symptoms, but a toxæmia which cleared on extracting teeth.

FIG. 2.—Radiograph showing extensive alveolar and periapical absorption.

FIG. 3.—Radiograph showing a large apical abscess with sclerosis of its bony wall and erosion of the tooth apex. The lateral incisor is root-filled and there is a little erosion of its apex.

FIG. 4.—Radiograph showing small areas of rarefaction at the apices of the bicuspid and molars with sclerosis of the surrounding bone. Patient suffered from pains in the back and along the course of the sciatic nerve as well as in the shoulder-joints.

FIG. 5.—Radiograph of molar with one root filled with opaque material, the other showing no sign of a nerve canal. There is sclerosis of the pericemental bone and secondary caries beneath the amalgam filling. Patient suffered from neuritis, which improved on removal of the tooth.

FIG. 6.—Radiograph showing retained stump with large abscess.

FIG. 7.—Radiograph of incisor teeth showing destruction of the pericementum around the apices of the central and lateral incisors and extensive destruction of the cancellous bone around. There is no definite boundary to the destructive process. Note the pulp stones in the central incisors.

FIG. 8.—Radiograph showing a large cyst with erosion of the apices of the central and lateral incisors which have had the pulps extracted and the root canals partly filled.

FIG. 9.—Radiograph showing "bulbous" roots to root-filled molar with periapical absorption.

FIG. 10.—Radiograph showing large area of periapical absorption with erosion of the apices of the first bicuspid, which shows secondary caries beneath the filling. There are similar but less marked changes in the second bicuspid.

FIG. 11.—Radiograph showing sclerosis of the pericementum due to the large filling and a normal antrum.

FIG. 12.—Radiograph showing erosion of the wall of the antrum and of the approximated root-filled bicuspid pericementum with dimming of the antrum.

FIG. 13.—Radiograph showing apical absorption around central incisor, not shown on "flat" radiograph.

FIG. 14.—Radiograph showing root-filled lateral incisor and canine. On the bicuspid side of the canine the pericementum will be seen pushed away from the side of the middle of the root. There is marked erosion of the apices of both teeth and very little root-filling, which shows signs of shrinking and retraction.

FIG. 15.—Radiograph of root-filled lateral incisor and canine, showing retraction and shrinkage of the root-filling preparation. The nerve canals are shown to be much wider in calibre. There is also an area of rarefaction of the periapical bone of both teeth and erosion of the apex of the lateral incisor.

FIG. 16.—Radiograph showing marked shrinking of the root-filling preparation and septic erosion of the apex of the tooth.

FIG. 17.—Radiograph of root-filled upper molar teeth, showing retraction and shrinking of preparation in anterior root and erosion and absorption around the distal root, which shows calcareous deposits. The floor of the pulp chamber had been perforated, and a deposit of calcareous material is shown on the projecting root-filling.

FIG. 18.—Radiograph showing root-filling in bicuspid roots; the filling projects beyond the apex in one, and an area of rarefaction has been produced in the surrounding bone.

FIG. 19.—Radiograph showing root-filling in bicuspid roots with areas of apical erosion and absorption. A small fragment of an instrument had been broken at the apex of the root and is lying in the rarefied area.

surrounding bone is sclerosed and very dense. This sclerosis most of us look upon as of the nature of a protective reaction against a chronic infection, and not as a breakdown in the resistance of the patient, though such patients often do gradually develop rheumatic symptoms, due probably to the long period of slow septic absorption.

*Group (c).*—Patients suffering from non-specific infective arthritis. The radiographs of the infected joints do not suggest ordinary bone sepsis: rarefaction, erosion, and sclerosis may be seen, but the changes are slow to form. They resemble the changes in the teeth of Group C. Numerous bacteriological researches have been made to attempt to discover the causal organism; various organisms have been suggested, but the lack of uniformity in the findings suggests that the condition is produced either by different organisms or by some bacteria or toxin which has not been discovered.

Price has shown that septic teeth from patients in this group, even when boiled, retain some toxin which is fatal to experimental animals. He found, too, that extracts from such teeth passed through a Berkefeld filter are also toxic to animals.

One of the most important points that Price has brought out is that the septic teeth from which absorption is taking place in patients with an inherited susceptibility to the rheumatic and degenerative disorders produce very little in the way of local clinical signs, which are small in magnitude. The fact that the patient has edentulous gums does not exclude the possibility of hidden dental sepsis. It is a fairly common thing to find that such patients have a retained stump which shows marked periapical erosion indicative of sepsis (as in Fig. 6). An x-ray examination may show definite evidence of apical sepsis of teeth which have not been filled and which show no evidence of caries. In some cases infection of the periapical area leads to the development of large cysts, which in the upper jaw may be mistaken for extension of the antrum (as in Fig. 8), but they can be readily distinguished from the latter by the fact that in the dental cyst the apices are denuded of the pericementum, whereas with the antrum extension the wall of the latter appears to be folded around the apices. Concomitant with the periapical erosion hypercementosis may occur, and the roots may assume a bulbous appearance on the radiograph. Such teeth may be very difficult to extract. In one case recently, where the radiograph showed similar changes to Fig. 9, the dental surgeon had great difficulty in extracting the teeth, and he told the patient that there had been a mistake in the radiographic report as the tooth was too firmly held to have been diseased. Brubaker reports that neuralgia, functional blindness and deafness, chorea, epileptiform fits, paralysis, cardiac neuralgia, insanity, and other related conditions have been cured by the extraction of hypercementosed teeth. In contralysination to hypercementosis we have erosion of the apices as a result of sepsis (as in Fig. 10). When the infected apex is near the antrum the infection may pass into the antrum (as in Fig. 12).

Radiographs with less marked changes are frequently seen, as in Fig. 13, which shows a large area of rarefaction, due to acute infection chiefly to the lateral side of the root-filled lateral incisor. The root-filling is not very opaque. It will be noted that the sclerosed pericemental bone is "wiped" out about half-way to the apex on this aspect, and to a lesser extent on the medial aspect of the lateral incisor. The area of rarefaction may not always be at the apex of the tooth, since many teeth have lateral canals through which the pericementum may be infected.

#### THE PULPLESS TOOTH.

A tooth which has been deprived of its pulp has lost its vital power, and inasmuch as it contains within its unfilled nerve canals and dentinal tubules (estimated as measuring three miles in length) dead organic matter which is brought into association with the circulating blood through the dentino-cemental foramina, it is liable, even if sterile when the pulp was extirpated, to be infected by any organisms circulating in the blood. It has been shown that, even when caries has only extended a quarter of the way through the dentine towards the pulp, approximately 50 per cent. of the pulps of such teeth are infected, and further, that it is impossible, with the most scrupulous care and the use of the best known bactericidal medicaments, to

be certain that the infection present has been eliminated. It is probably very rare for the nerve canals to be completely filled, even though the canal be simple and straight, as most of the substances used cannot be made to fill the canal accurately, and owing to absorption of the solvents used in the preparation the filling contracts and leaves a space which, with the dentinal tubules, is unprotected by any vital agents and is liable to become the storage place for bacteria and toxins. Price says:

"It is to be remembered that a small portion of a gangrenous pulp beneath a root-filling is equivalent to an entire gangrenous pulp as a cause of pericementitis. The vast majority of cases occur as a sequel to putrefaction of the pulp, either before or after instrumentation or as a result of infection of the apical tissue by instruments either unsterilized or reinfected by contact with oral fluids, septic fingers, etc."

When the nerve canal is delta-like, or has lateral openings, the pulp remnants cannot be removed, nor can the canals be suitably filled even with impregnation methods. To get out of this difficulty some authorities resect the apex of the tooth.

Bacteriological examination has shown that, no matter what medicament is used in the treatment of infected apices, dressings left in for forty-eight hours are found to be infected, and that even when all care has been used root-filled teeth may be a source of great danger to the patient. Experimentally it has been proved that such root-filled teeth may contain bacteria or toxins which, together or separately, produce toxæmia and death when inserted into animals.

Mayo says:

"Although the possessor of a tooth with dead pulp without local reaction may be enabled to eat better for a time, he is conducting his health on borrowed capital, as he may not have a physician or dentist who will appreciate that the disease or broken health that may develop is due to such an apparently trivial cause that persons comparatively well may later develop a variety of diseases that destroy health and happiness, if not life."

Whilo Inglis says:

"At present it looks as though no root-filled tooth can be considered other than as a life risk, while sterile filled roots can be infected from other sources of infection, of which there are many."

#### RADIOGRAPHIC PITFALLS.

The errors in dental radiographic diagnosis may be due to (a) faulty photographic and radiographic technique; (b) misinterpretation of the radiograph.

With regard to (a) it can be said that the manufacturers have done their best to produce an x-ray unit which is as simple in working as any snapshot camera. It is common knowledge that with either kind of apparatus the proportion of films of good quality is dependent upon the care, skill, and experience of the operator. The simplicity of the apparatus will enable the most ignorant beginner to obtain chance successes, and these chance successes are stored and exhibited to give a sense of self-satisfaction which tends to prevent further progress. It is not to be wondered at, therefore, that marks on radiographic films due to faulty technique may (1) be interpreted as pathological changes, which are not found at subsequent operation; (2) mask a pathological lesion which is present. I have known of a number of cases in which the pathological lesion was missed because the films were flat. Fig. 13 is an example of such a case. No amount of clinical or pathological knowledge will enable anyone to give a diagnosis from a faulty film.

#### Misinterpretation of the Radiograph.

This is due chiefly to: (1) lack of experience in interpreting radiographic shadows; (2) lack of knowledge of general and dental pathology.

With regard to (1) every radiologist who has correlated the radiographic and clinical, operative or post-mortem, findings knows that the radiograph may show only slight changes even when a massive lesion is present. Thus with acute inflammatory lesions of the skeletal tissues the radiograph may give no sign; even with the enormous development which one sees in some cases of periosteal sarcoma the radiograph may show nothing abnormal or perhaps a little localized thickening of the periosteum. It can almost be said, particularly in acute conditions, that the more attractive the physical signs, the less the radiographic signs.

In the case of dental radiography, as the lesions are often small, it is all the more important to pay attention to the finer details.

As regards (2) there is no question that for the best interpretation of radiographs the observer must have a good knowledge of the normal and pathological anatomy of the part. Most books dealing with the radiography of the teeth instance the interpretation of the mental and palatine foramina and loculi of the maxillary antrum as areas of periapical absorption, so that these mistakes are hardly likely to be repeated except by the beginner; even if they are, the worst that can happen is the sacrifice of one or perhaps two sound teeth.

The result of the wide knowledge of the faulty interpretation of these foramina has no doubt been responsible for the much more grave error which is brought to one's notice from time to time—that is, the interpretation of a definite periapical absorption as a normal foramen or sinus. It would almost seem that the larger the cyst the greater the possibility of it being interpreted as a shadow of the antrum. (See Fig. 8.) This is of great importance, because the systemic disease from which the patient is suffering continues or increases in severity as the suspected cause has been overlooked and allowed to remain—there being no local signs apparent to the patient or the clinical observer.

## SOME PROBLEMS OF GLYCOSURIA.\*

BY

GEORGE J. LANGLEY, M.D.LOND., M.R.C.P.,  
HONORARY PHYSICIAN, SALFORD ROYAL HOSPITAL.

THE introduction of insulin in the treatment of glycosuria has enabled us to overcome the urgency of diabetic coma in a way never before possible, but many problems remain.

Can the administration of insulin be regarded as a replacement therapy? There is much evidence that such is the case. It is usually recognized that the respiratory quotient rises under its influence from 0.7, indicating metabolism of proteins and fats, to unity, indicating the metabolism of carbohydrates. The glycogen store has been shown to increase very materially under its use. The blood sugar curve—that is, the amount of sugar in the circulating blood—is very materially altered; whereas the administration of glucose alone led in one case to a rise from 0.2 to 0.4, the combined administration of glucose and 20 units of insulin resulted in a fall to 0.05.

Regarding insulin, then, as an efficient replacement therapy, we are still left with very definite limitations.

1. The amount of insulin required depends upon the amount of carbohydrate to be dealt with.
2. The insulin must be given at the time of carbohydrate absorption.
3. The duration of maximum insulin efficiency would appear to be only four hours.
4. The preparation must be given hypodermically.

A consideration of these factors at once shows the very serious limitations of this line of treatment. The daily life of most persons includes four meals, which vary in themselves, and from day to day, as to their carbohydrate content. A complete replacement therapy would therefore demand four doses of insulin, given hypodermically, in

quantities calculated to deal accurately with the carbohydrate content of each individual meal. This is quite impossible, and it is found that patients are very reluctant to tolerate more than two hypodermic injections daily. The diabetic patient under insulin treatment, therefore, finds himself still limited as to time, quantity, and quality of food; he must be on a diet as rigid as heretofore, although containing material previously forbidden; and, in addition, must tolerate two hypodermic punctures every day. Two of the meals will be relatively generous, while the other two are designed to contain the minimum amount of carbohydrate.

There are two schools of thought in the composition of diabetic diets. One believes that the best results are obtained by keeping the patient on the lowest diet which will maintain weight and strength, and, in consequence, the minimum possible daily dose of insulin. The other school holds that a generous diet allowing for plenty of available metabolic material, with a relatively large dose of insulin, is the better line of treatment. A careful paper by Rabinovitch in the *Quarterly Journal of Medicine*, in which the results of about 1,200 cases have been analysed, has led him to the conclusion that a minimal diet yields the best results. This is the type of conclusion usually arrived at by a statistical method, but it is liable to omit the human factor. It is a matter of common experience that diabetics generally not only have larger appetites in consequence of the disease, but that they have always liked or required quantities of food beyond the average. If this be so, it is possible that treatment including a generous diet will be more satisfactory to the patient and be more likely to be maintained; and it will prove much less irksome than treatment along rigidly abstemious lines. It is possible that medical practitioners generally underestimate the limitations from which these patients suffer; the continued dieting, the regularity of their meals, and the ever-recurring hypodermic punctures, with careful consideration of any food provided outside their own homes, make for a monotony which usually proves hard to bear, and the more rigid its limitations the greater the mental load. If insulin can legitimately be regarded as a replacement therapy, then, in my opinion, it should be used to replace so far as it is practicable; the introduction of double strength insulin has enabled this to be achieved more easily than was the case when only one strength was available.

The relation of proteins, fats, and carbohydrates in the total diet offers a further problem to which no generally accepted answer has yet been found. Anything approaching the usual proportions of the average meal in this country would involve the use of impossibly large doses of insulin. Even the proportion found in milk (protein 3, fat 4, carbohydrate 5) requires relatively large injections, but is probably a basis which yields good results.

Certain difficulties present themselves in relation to groups of cases. The man who has to earn his own living by hard labour obviously needs a more generous diet than the well-to-do woman with no particular occupation. The dieting of diabetic children offers great difficulty, for they must be given suitable food in sufficient quantity to permit of adequate growth, and they are nearly always severe cases. It has been my experience that no satisfactory result can be obtained among the younger patients unless three insulin doses a day are given.

Changes in dieting when the insulin dose has been established are from time to time necessary, the commonest cause, perhaps, being loss of appetite which results from some pyrexial illness. There is no doubt that this constitutes one of the greatest dangers to the diabetic to-day. If the patient does not take the carbohydrate part of his diet the insulin would appear to become unnecessary. It frequently happens that a diabetic patient contracts influenza, or some other disease associated with a rise in temperature, and is put on a low diet without insulin. The metabolic processes are increased with the rise in temperature, the carbohydrates being the chief source of heat production; in this respect the diabetic fails completely, with the result that the proteins and fats are inadequately split, a rapidly rising ketosis occurs, and coma becomes imminent. The occurrence of pyrexia in a

\* A paper read before the Lancashire and Cheshire Branch of the British Medical Association.

diabetic is an indication for more insulin and more carbohydrate, not less. In my own cases I have found milk and glucose, with sufficient insulin to avoid acetone in the urine, a satisfactory line of treatment, but I have always had the advantage of frequent blood sugar examinations, and have further aided in keeping the blood sugar within reasonable limits, but at the cost of enormous doses of insulin. It is further tenable that much may be done to avoid coma by the administration by the mouth of sodium bicarbonate and sodium phosphate, the action of the latter depending upon the fact that acid sodium phosphate is secreted in the urine. Large doses of both salts can be added to each milk feed.

The experiments of Allen with partially depancreatized dogs showed that plentiful carbohydrate with high blood sugar caused early death, whereas carefully regulated diets maintaining a low blood sugar allowed the dogs to live considerably longer. The question therefore arises when a diabetic with high blood sugar comes under treatment whether the maintenance of a normal blood sugar level will permit of any degree of pancreatic recovery. It is my experience with diabetics of middle life that if the diet and insulin dose be correctly balanced and maintained for some months the dose of insulin required for the same diet does fall, but that the fall is slow and gradual. No case of complete recovery—that is to say, with a seriously abnormal response to 50 grams of glucose—has occurred with sufficient completeness to show a normal blood sugar curve after treatment; yet a few cases have given remarkably satisfactory results, more particularly those arising from septic absorption.

The large amount of work on diabetes during the past few years has revealed a good many fallacies among our cherished beliefs. Most of us were taught that the diabetic was peculiarly liable to septic infection, whereas it is now generally recognized that septic infection is prone to give rise to diabetes. Recently a woman, aged 32, was admitted to the Salford Royal Hospital with a carbuncle of the neck of seven days' duration. Sugar was present in the urine with much acetone, and although the patient was not in coma she was sufficiently sleepy to require rousing before she could take any notice. The slough was removed from the septic area and the blood sugar held in check by insulin. At the end of a week it was found that the patient could take a diet of over 2,000 calories, containing 85 grams of carbohydrate, without insulin and without either glycosuria or acetonaemia. She was discharged on a curtailed carbohydrate diet and without other treatment. Another patient, aged 60, was known to have had a very extensive fistula in situ and glycosuria for over ten years. Two operations and a long period of dressing produced a complete healing of the fistula, and the patient was able to take, without glycosuria, a diet restricted in carbohydrates, but permitting a very fair allowance of stout. Such cases, presumably septic in origin, occur in every diabetic clinic, and are very satisfactory once the originating sepsis can be cleared up.

The following case appears to me to belong to a different category.

A girl, aged 18, had been treated for a fortnight for soreness of the mouth. No local lesion was found, and various palliatives were tried without benefit. She had previously been in robust health. Some degree of thirst developed; the urine was tested and was found to contain sugar. The same day she became unconscious, the urine being then loaded with sugar and acetone. The coma lasted thirty-six hours in spite of the administration of over 300 units of insulin. Recovery gradually ensued, and by the end of a week the patient was taking a diet of 1,800 calories with 40 units of insulin twice daily. Although the diet remained unchanged, the dose of insulin had to be gradually reduced on account of recurrent hypoglycaemia, until at the end of three weeks of treatment the diet could be taken without insulin, and without either glycosuria or acetonaemia. At the end of a month's treatment she returned home on the same diet but without insulin, and remained energetic and well with no glycosuria. Six weeks later the festivities of Christmas proved too much for her self-control, and after two days of feasting the urine was loaded with sugar, which did not disappear until the original diet of 1,800 calories had been regularly adhered to for a week. Since then there has been no lapse, and the patient remains very well.

The temptation is almost irresistible to believe that diabetes in young subjects has an acute and infective origin; the onset in many of these cases suggests it strongly. If this be so, and they are adequately treated

from the first, to avoid any long period of raised blood sugar, which is known to be so deleterious to the islet tissue, it is surely not too much to hope that some of them will actually recover completely, and so be saved from the disease.

The feasibility of operation upon diabetic patients has undergone complete change with the introduction of insulin. The usual method adopted is to give the patient an adequate diet and the required insulin dose to maintain freedom from glycosuria for a week. On the day of operation the usual purging in preparation is dispensed with, and the patient before receiving the anaesthetic is given 50 grams of glucose and 10 to 20 units of insulin, dependent upon the amount of insulin required for his diet, as forming an estimate of the severity of his pancreatic deficiency. Chloroform is countermanded as an anaesthetic, but ether appears to be quite safe. Post-anaesthetic vomiting and the general dietary upset, consequent upon the anaesthetic, may occasion some difficulty in determining the required insulin dose for the first two or three days after the operation, otherwise this procedure causes little trouble.

Some time ago a woman, aged 38, who had been known to have diabetes for ten years, went into coma and remained unconscious for six days, in spite of very large insulin doses. She ultimately made a very good recovery, and led a fairly useful life, taking about 100 units of insulin daily; she was regarded as a severe case of diabetes. A year later she was seized with severe abdominal pain and vomiting, and some hours later a gangrenous appendix was successfully removed by Mr. Macalpine. The patient took the anaesthetic well, and made a remarkably good recovery without any signs of coma. The wound healed up well, as in ordinary cases. She unfortunately developed femoral thrombosis, which required prolonged rest in bed, but she is still alive and well and able to lead a normal life except for her dietary restrictions.

To undertake a laparotomy in this particular case appeared to be courting disaster, but very little trouble was experienced from her diabetic condition, and I personally do not regard diabetes as a contraindication to operation to-day.

It is now generally recognized that glycosuria does not always mean diabetes, and renal glycosuria in which the kidney passes sugar with the urine at an abnormally low concentration in the blood is a fairly common occurrence. But there are three other conditions which are perhaps not quite so frequently looked for and understood. The occurrence of sugar in the urine after mental excitement is fairly common. It was found in a considerable percentage of students during final examinations, and in football teams after exciting and important matches, and is believed to be due to the physiological mobilization of sugar resulting from increased adrenal secretion. During the past year three cases have come under my notice in which the diagnosis between cerebral haemorrhage and diabetic coma had to be made. All of them were very extensive cerebral haemorrhages, but all the patients had glycosuria, presumably caused by the haemorrhage, as one of them was known not to have had any urinary sugar on the morning of the stroke. The third condition is the frequent association of diabetes with exophthalmic goitre. In the majority of hyperthyroid cases the tolerance for sugar is within the normal limits, while in others there is a very definite intolerance, with abnormal rise and slow fall in the blood sugar content. These cases appear to be materially improved by insulin treatment, both as regards their diabetes and their hyperthyroidism.

Lately I have had under my care a patient with well-marked hyperthyroidism, who has a very low renal leak point and slight carbohydrate intolerance. In spite of this, three-quarters of the thyroid was successfully removed by Mr. Jefferson without any untoward event and with considerable benefit, but without the help of insulin.

Some form of therapy which can be administered by the mouth, and with a longer period of activity than that of insulin, is still being diligently sought. No such thing has as yet been found, but two attempts have been made. Insulin can be absorbed in the stomach, but only in very small quantities, if given either with alcohol or with saponin, but the quantity is not sufficient to make it practicable. The other attempt depends upon the fact that guanidine was thought by Noel Paton and Findlay to have a definite effect in lowering the blood sugar. The drug is much too toxic to be employed, but various derivatives have

been tried, and some can be tolerated. A product of this group known as synthalin is now on the market. It is doubtful whether it can be administered in sufficient doses to control the blood sugar, but there is no doubt that the drug does give rise to considerable gastritis and some diarrhoea. This is likely to control the amount of food ingested, and by so doing will materially improve the middle-aged diabetic, who eats and drinks too much.

## PULMONARY FIBROSIS:

### AN INVESTIGATION INTO THE ORIGIN AND COURSE.

BY

C. DE W. KITCAT, M.R.C.S., L.R.C.P.,

RESIDENT MEDICAL OFFICER, BROMPTON HOSPITAL FOR DISEASES  
OF THE CHEST;

AND

T. HOLMES SELLORS, M.A., B.M.Oxon.,

CASUALTY SURGICAL OFFICER, MIDDLESEX HOSPITAL; G. H. HUNT  
TRAVELLING SCHOLAR, UNIVERSITY OF OXFORD.

PULMONARY fibrosis in childhood inflicts such a physical handicap on its victims in later life that a short account of our attempts to investigate the origin and subsequent course of the disease may be of general interest and lead to further study. The materials for the investigation have been gathered from the records of the Brompton Hospital, and in the main confirm those recently published by Dr. Burton Wood.<sup>1</sup> We are using the term "pulmonary fibrosis" because it is at present the most familiar designation of the disease known as fibrosis, fibroid induration, chronic broncho-pneumonia, chronic basal pulmonary catarrh, and early bronchiectasis—which titles, we believe, indicate phases of the same condition.

Pulmonary fibrosis may be a disease entity *per se*, but it is commonly secondary to an attack of broncho-pneumonia, usually of the subacute variety, following some of the infectious fevers, especially measles and whooping-cough. Broncho-pneumonia invariably produces some degree of bronchiolar dilatation, and persistence of the inflammation promotes fibroid thickening of the bronchioles and air cells; moreover, the slight dilatation is in itself a cause of the cough which tends in vicious sequence to increase the weakness of the tubular walls. Pulmonary fibrosis begins in early childhood, a fact explained partly by the special liability at that age to infection by measles and whooping-cough, and partly by certain peculiarities in the anatomy of the lungs—namely, the relatively large calibre of the bronchi, the thickness of their epithelial lining, and the thick, but yielding, walls of the alveoli; these are embryonic and infantile distinctions which have disappeared in a healthy child by the fifth year.

Quite early in the investigation we found it essential to impose certain arbitrary limits to our search so as to keep it within reasonable bounds, and therefore made use of only such cases as fulfilled the following conditions:

(a) The age at the first examination must have been under 15 years.

(b) Each case selected must have been under observation for at least six months.

(c) Physical signs must have been present at the first examination and persisted over the whole period of attendance.

(d) At least five years must have elapsed since the last attendance.

Cases with any evidence of pulmonary tuberculosis or established bronchiectasis (at the first attendance) were excluded.

More than 23,000 notes from the out-patient department of the Brompton Hospital were reviewed, and 259 patients apparently suitable for investigation were followed up. Of these, 7 were found to have died and are not included in this report, but 53 attended and form the basis of inquiry.

At our examination a full clinical survey was made, with special reference to the following features: (a) Clinical history since last attendance at hospital. (b) Symptoms with particular reference to normal life and work. (c) Physique and capacity for work. (d) Physical signs in lungs.

### CLASSIFICATION.

The 53 cases are classified from an economic standpoint; we use the term "fit" to imply the capacity of an individual for a normal useful life.

1. Fit, without signs or symptoms—resolution has taken place in the interval ... ..	9 (17%)
2. Fit, but with physical signs—permanent injury to lung tissue, but no apparent impairment of general health ... ..	16 (30%)
3. Not fit and with physical signs—permanent injury to lung tissue accompanied by some degree of constitutional disability ... ..	23 (43%)
4. Bronchiectasis has supervened since last examined ... ..	5 (10%)

### COMMENTS.

*Complete Resolution.*—This group is small but definite; the notes show that no improvement had accrued during the period of treatment, and it is impossible to judge the age at which the induration resolved.

*Persistent Signs, but no Symptoms.*—It is remarkable that a good physique and general health can be maintained in spite of permanent damage to lung tissue.

*Persistent Fibrosis.*—These cases are the most numerous, and, with the next group, constitute a grave indictment of present treatment of the disease. The symptoms and signs are compatible in most cases; there is an increased tendency to coughs and colds, and the majority are confined to bed or house at frequent intervals during the winter months.

*Bronchiectasis.*—As mentioned previously, we rejected cases which showed the presence of established bronchiectasis while attending hospital, and this group only includes those in which the condition has developed since last seen. The number is small, but in addition the accounts of the seven deaths suggested this as the terminal cause.

*Syphilis.*—None of the patients examined exhibited clinical evidence of syphilis.

*Pulmonary Tuberculosis.*—All patients were examined for tuberculosis, and only one was found to have tubercle bacilli in the sputum. This case is not included in our figures.

### CAUSATION.

The primary causes were:

	Cases.
Measles alone ... ..	14 (26.5%)
Whooping-cough alone ... ..	8 (15%)
Measles with whooping-cough ... ..	16 (30%)
"Pneumonia" ... ..	14 (26.5%)
Scarlet Fever ... ..	1 (2%)

An accurate history of broncho-pneumonia following these fevers could not be definitely established, but was suggested in the majority of cases. Broncho-pneumonia is a frequent and often fatal complication of measles, and among the poor or weakly is apt to run an irregular but persistent course. It may last as long as six weeks, or even more, and in such a case fibrosis will probably ensue. Broncho-pneumonia is also the most serious complication of whooping-cough, and accounts for nine-tenths of the deaths from the disease. Our cases support the view that these two infections are mainly responsible for the production of pulmonary fibrosis. As the severity of both decreases with each year after the second, the fatalistic attitude of the laity—"let them catch it and get it over"—is to be deplored; since after the fifth year there is little danger of severe pulmonary complications to be feared from the infection or its sequel, every effort should be engaged to guard young children from any risk of contracting either, and especially should children with measles be protected from whooping-cough. "Pneumonia" appears frequently in the histories and gives rise to some confusion, for lobar inflammation is probably not intended; it is not a frequent complication of the fevers, and if present is always of a lobular variety. It would appear likely that a combination of impaired percussion note, weakened puerile breath sounds, and crepitations occurring in a febrile child might well at first sight suggest a diagnosis of lobar pneumonia, whereas actually the condition represents an exacerbation in a fibrotic lung.

## SYMPTOMS AND SIGNS.

The following symptoms and signs were found in patients who were unfit. Cough was invariably an early symptom, aggravated by cold and damp weather, and tending to become worse year by year; very marked liability to take cold was one of the most prominent features of the condition. If the cough became persistently paroxysmal a definite dilatation of the bronchioles was to be assumed. Slight breathlessness on exertion, and in advanced cases slight cyanosis, with parrot-bill clubbing of the fingers, pointed to right heart embarrassment. Contrary to the prevalent opinion, we found that the clubbing tended more to the early "parrot-bill" than the "drumstick" type. The sputum was scanty in quantity without characteristic peculiarity, unless bronchiectasis had intervened. The disease was almost always unilateral. The configuration of the thorax was often affected, there being slight scoliosis with narrowing of the interspaces and drooping of the shoulder; retraction to a degree indicating extensive pleural adhesion was not observed in any instance, nor was the heart markedly displaced. Respiratory movements and sounds were diminished over the diseased lung, and adventitious sounds were occasionally present. X-ray investigation following lipiodol injection into the bronchi would have been desirable, but was impracticable on account of the patients' daily routine; radiograms were taken in some cases.

## TREATMENT.

Without entering closely into details we would like to point out that certain indications are clear, of which the need of more efficient prophylaxis is the most prominent. Broncho-pneumonia (whether so-called primary or secondary to measles and whooping-cough) is well known to be the cause of a large number of deaths in childhood, but it is not so generally recognized that as a persistent sequel of these infections it leads to the disability which is the subject of this investigation. Too much emphasis, therefore, cannot be laid on the after-care of cases of measles and whooping-cough. In the treatment of incomplete resolution attempts must be made to reventilate the sclerosed areas by means of breathing exercises; patients are now being treated in this manner at Brompton with very beneficial results, but it is as yet too early to speak of permanent benefit. In early cases reventilation and expansion of lung are desirable, but where bronchiolar dilatation has occurred and appears to be becoming permanent, natural or artificial methods of reducing the size of the thoracic cavity to allow for the ensuing cicatrization should be considered. If the child is young enough the chest wall will probably retract sufficiently for some degree of compensation; but when the thorax is too rigid more radical measures—artificial pneumothorax, phrenicotomy, or more extensive surgical measures—may be indicated. Failing employment of such procedures, permanence of signs and symptoms may be expected, and treatment can only be symptomatic.

## Illustrative Cases.

## GROUP I.

A boy, aged 5½ years. Whooping-cough one year previously, since when he was never really well; persistent cough. Examination showed impaired percussion note, weak breath sounds, and crepitations at the right base. The patient attended for six months, at the end of which time the signs were still persisting. Re-examined aged 21. Has been very well for many years, and is able to do heavy work. All physical signs completely cleared up.

A boy, aged 11. Measles two years previously, followed by "pneumonia," since when he had had constant cough and sputum. Examination showed impaired note, weak breath sounds, and râles at right base. Diagnosed as fibrosis of lung. Signs did not clear up. Re-examined aged 23. Now perfectly well, working. Signs no longer present.

## GROUP II.

A girl, aged 7½. Measles and whooping-cough three years previously, since when frequent cough. Examination showed rhonchi and crepitations at both bases. Attended for seven months; signs did not clear up.

Re-examined aged 22. Healthy-looking woman; feels well and is able to work. No cough or sputum. Impaired note, weak breath sounds, and post-tussive crepitations at right base.

A girl, aged 7½. Whooping-cough three years previously, since when persistent cough. Examination showed impaired note, weak

breath sounds, and crepitations at right base. Diagnosis—? early bronchiectasis. Signs persisted during attendance.

Re-examined aged 23. Has been quite well for years. Able to work. Signs as before. No cough or sputum. Not subject to colds.

## GROUP III.

A girl, aged 5. Measles one year previously, since when cough and dyspnoea. Examination showed numerous crepitations at the left base, and these persisted during six months' attendance.

Re-examined aged 24. Pale, muddy complexion. Always has cough and about half an ounce daily of non-offensive sputum. Exacerbation of symptoms occurs every two to four months, necessitating retirement to bed. Able to work between attacks, but not completely fit.

A boy, aged 12½. Measles and whooping-cough two years previously, since when persistent cough. Examination showed weak breath sounds and coarse râles at the right base.

Re-examined aged 20. Always has cough with slight amount of sputum. Frequent colds, able to work, but not completely fit. Signs as before.

## GROUP IV.

A boy, aged 8½. Measles followed by whooping-cough when 6 months old, since when persistent cough. Examination showed coarse râles at both bases. The child never coughed up any sputum, but the signs did not clear up.

Re-examined aged 13½. Typical bronchiectasis with offensive sputum, confirmed by x-ray examination.

A girl, aged 6. Whooping-cough one year previously, since when persistent cough. Examination showed numerous crepitations at the right base. Diagnosis—? bronchiectasis.

Re-examined aged 14. Typical bronchiectasis with offensive sputum.

## CONCLUSIONS.

1. Pulmonary fibrosis of non-tuberculous origin frequently produces grave disability and seriously reduces the subject's economic efficiency; on the other hand, a reasonable proportion establish an "immunity" and labour under no apparent disadvantage.

2. Pulmonary fibrosis is a not infrequent consequence of the protracted form of broncho-pneumonia which follows measles and whooping-cough.

3. Protection against measles and whooping-cough in the first five years of life would tend to prevent its incidence.

4. Apart from prophylaxis, amelioration, if not absolute cure, may be expected by improved methods of treatment.

It will be noted that we have used the term "pulmonary fibrosis" throughout as a label for the condition, but this is not altogether satisfactory, and there would appear to be a distinct need for an official discussion with a view to determining the nomenclature.

Our thanks are due to the honorary staff of the Brompton Hospital for permission to make use of their records, also to the lady almoners for their assistance in tracing cases. For suggestions and advice we are indebted to Drs. G. E. Beaumont and W. H. Lister.

## SOLITARY ULCER OF THE BLADDER.

BY

GUY CHAMBERS, F.R.C.S. (ENG.),

HONORARY SURGEON, ISLE OF WIGHT COUNTY HOSPITAL; LATE CLINICAL ASSISTANT, ST. PETER'S HOSPITAL FOR STONE.

It is a matter of some interest that a review of the literature on general and urinary surgery reveals the fact that this condition is enshrouded in a certain degree of obscurity. In some works the disease fails to be identified as a clinical entity from other varieties of chronic ulceration, in others it is not even mentioned. Certain well-known writers, on the other hand, give the subject considerable attention and description under titles which appear to be synonymous.

Rowlands and Turner (1927) describe the chronic or callous ulcer of the bladder, which occurs nearly always in young men, but occasionally in women who have borne children. Haematuria is a fairly constant symptom. The condition was mentioned by Fenwick in 1900,<sup>1</sup> and again in 1904.<sup>2</sup> V. C. Hunt<sup>3</sup> discourses on submucous ulcers of the bladder, advises their excision, and the treatment of septic foci affecting the tonsils, teeth, nasal sinuses, etc.

Cabot describes a solitary ulcer that may be either acute or chronic. He mentions also an elusive ulcer that occurs chiefly in females and is associated with great frequency of micturition but without haematuria.

Frank Kidd, in his work on urinary surgery (1910), gives a clear and concise description. The causes of simple ulcer are classified as consecutive, spontaneous, and symptomatic; the consecutive variety being due to mechanical pressure of foreign bodies, stones, etc., the spontaneous due to bacterial infection of the bladder wall, and the symptomatic occurring in the course of diabetes or disease of the nervous system.

The second variety, which is the type under present discussion, is subdivided into acute perforating and chronic solitary. It will thus be seen that the nomenclature and description of this disease are somewhat varied, and that a brief account of its etiology, pathology, and clinical features may be of interest before relating a case which was sent to me some months ago.

#### *Etiology.*

This is not clearly understood. There is evidence in some cases of a toxic focus, such as pyorrhoica, septic tonsils, or sinus infection. Haematogenous infection is regarded as the probable cause. Comparison is made with the theory of gastric ulcer from infective emboli through the blood stream. The patients are usually young males with no antecedent urinary trouble or venereal history.

#### *Pathology.*

The ulcer is single, submucous, and shallow. In time it penetrates the muscular wall, and, in rare cases, the entire wall of the bladder, with subsequent infection of the pelvic cellular tissues or peritoneum, according to the site of the lesion. Cystitis appears before long, and the ulcer becomes encrusted with phosphatic debris. The ulcer is usually half to three-quarters of an inch in diameter. It is situated most frequently on the posterior wall, above and internal to the ureteric orifice. The margin is slightly raised; the base is somewhat shaggy and covered with fibrin or blood clot with, perhaps, some phosphatic encrustation.

#### *Clinical Features.*

The early symptoms are increased frequency of micturition and intermittent haematuria. Later the haematuria becomes more persistent and profuse, with strangury and pain referred to the penis. The general health becomes undermined in a very short time, with loss of weight and a moderate degree of anaemia. The symptoms of cystitis are superadded.

#### *Differential Diagnosis.*

Examination by cystoscopy will, of course, localize the source of the haemorrhage, and the ulcerated area found in the bladder must next be differentiated from tubercle and neoplasm. Bleeding may be so profuse during instrumentation as to make visibility difficult or impossible. Suprapubic cystotomy, for diagnostic as well as curative purposes, may have to be performed. Repeated bacteriological examination of the urine is made to eliminate tubercle. Coliform infection should be identified by the same means. Adherent blood clot at the site of the ulcer may lead to the suspicion of malignant growth, especially when cystitis is present.

The diagnosis is confirmed finally by the microscope. A section of the ulcer shows chronic inflammatory tissue near the edge, with new blood capillaries, and organized blood clot covering the base.

#### *Treatment.*

Palliative measures are not, as a rule, satisfactory. Curettage of the ulcer, and caustic applications, through a suprapubic opening, have met with varying success. Treatment by diathermy through the cystoscope is successful in early cases. Resection of the ulcer is the most satisfactory method. It should be done early. The presence of cystitis necessitates preliminary drainage with all the attendant difficulties of a second operation later. An ulcer situated in the trigone is best dealt with by the cautery.

#### *Case of Solitary Ulcer: Partial Cystectomy: Cure.*

A youth, aged 15, noticed blood in his urine during the afternoon of June 10th, 1927, following exercise at rowing earlier in the day. At night the urine was clear. The next morning blood was again present, but passed off towards the evening. The haematuria was painless and recurred each day. On June 17th,

as the condition was not improving under medical treatment, I was called in consultation by his doctor with a view to further investigation. His parents declared that he had looked tired and thin for the past two or three months. He had always been delicate since childhood. He was, however, a keen athlete, and played regularly at cricket or football, and was fond of rowing.

*Past Illnesses.*—He had tonsillitis and quinsy when  $3\frac{1}{2}$  years old, tuberculous glands in the neck, which were removed by operation, when he was 7, and typhoid fever at 8 years of age.

*Present Condition.*—He was pale, of muddy complexion, thin but wiry, and intelligent. Temperature and pulse were normal; blood pressure, 110 mm. Hg. The amount of blood in the urine was variable each day, at times half to a third of its bulk, at others almost clear. The haematuria was symptomless, but later he complained of frequency of micturition and a feeling of discomfort at the base of the penis. The urine was free of casts, bacteria, and, apart from blood, showed no other pathological cell elements. The urea concentration test indicated good renal efficiency.

*Cystoscopy.*—This had to be performed on three occasions on account of persistent bleeding. It was only on the third examination that a clear view was obtained. The ulcer was situated above and to the outer side of the right ureteric opening. Its size could not be clearly ascertained as it was only partly visible, but after operation it was found to be about three-quarters of an inch in diameter. There appeared to be a small pouch or depression of the wall surrounding the ulcer, over the edge of which several streams of blood could be seen trickling downwards like a cascade or waterfall.

*Operation.*—On July 8th I explored the bladder. The ulcer was bleeding freely; it was the size of a sixpence, but well clear of the right ureter. I resected a portion of bladder wall including the ulcer—approximately one and a quarter inches by one inch—closed the bladder, and drained by a suprapubic tube for a few days. The prevesical space was drained also.

Convalescence was normal. At the end of three weeks the wound was quite healed and the patient passed water naturally. On July 28th he left hospital.

During the following two months the urine was examined at weekly intervals and was found normal and free from blood on each occasion. There was no pain or frequency complained of at any time.

Before operation his weight was 6 st. 9 lb. On September 27th, two and a half months after operation, he weighed 8 st. He was then looking well, with a fresh and healthy colour, and stated that he felt better than he had done for several months. He was taking moderate outdoor exercise.

*Pathological Report* (from the Clinical Research Association).—"The section shows a superficial ulceration covered with partially organized blood clot. The epithelium is represented by a very small compressed fragment. There is inflammatory infiltration, but no sign of tuberculousis."

## LARYNGEAL DIPHThERIA IN OLD AGE.

BY

J. D. ROLLESTON, M.D., M.R.C.P.,

MEDICAL SUPERINTENDENT, WESTERN FEVER HOSPITAL, LONDON.

LARYNGEAL diphtheria is rare at any period of adult life, and becomes increasingly so with advance in age. In a paper published some years ago<sup>1</sup> I illustrated this by the fact that my experience had been limited to four examples of the kind among 1,156 cases of laryngeal diphtheria, with or without faucial and nasal involvement, admitted to hospital between August 17th, 1899, and December 31st, 1915, during which period 11,313 diphtheria patients of all ages were admitted, 821 being aged 20 years and over. Of the four cases, three of which were fatal, the youngest was aged 24 and the eldest 45.

The present case is remarkable for the much greater age of the patient, and is, as far as I can recall, the oldest example of diphtheria that I have seen, with the exception of a moderate faucial attack in a woman aged 94, recorded by G. W. Ronaldson in this Journal.<sup>2</sup>

The patient was a woman, aged 76, who was admitted to hospital on March 20th on the sixth day of disease. On admission the tonsils and uvula were covered with membrane, which was also visible on the tip of the epiglottis. The cough was croupy and the voice was lost. A culture of diphtheria bacilli was obtained from the throat. An intramuscular injection of 24,000 units of antitoxin was given on admission and repeated on the following day. No other active treatment, local or general, was employed, and rapid disappearance of the membrane and laryngeal symptoms took place. No complications ensued, apart from a trace of albumin in the urine from the tenth to the twelfth day, but in view of the severity of the attack and the likelihood of subsequent paralysis it was considered advisable to keep the patient in bed till the forty-second day. On her discharge from hospital on the fifty-sixth day she showed no sign of paralysis and the knee-jerks were active.

Apart from the rarity of laryngeal diphtheria in advanced life the case is of interest in the following respects. The pernicious doctrine which has received support in two of the most recent textbooks on diseases of the throat—that antitoxin is of no value after the fifth day of disease—is falsified by the rapid subsidence of the symptoms after injection of the large doses which the patient received. The absence of any serum reaction was due partly to the use of a refined serum and partly to the fact, which I have illustrated on several previous occasions, that serum reactions are often absent or ill marked after severe angina in spite of the administration of large amounts of serum.

Recovery was all the more remarkable as the prognosis of laryngeal diphtheria in adult life is usually unfavourable.

Lastly the case is an excellent example of what C. Zoeller,<sup>2</sup> who has recently recorded an attack of laryngeal diphtheria in a middle-aged man, describes as the “caprices of spontaneous immunization.”

The great majority of town dwellers—especially those in capitals such as London and Paris, where diphtheria is endemic—undergo a process of occult spontaneous immunization, and only a comparatively small minority contract the disease. In some cases, however, this process of spontaneous immunization does not take place. Zoeller's patient was a colonel aged 50, who, in spite of the fact that he had been living in Paris and other communities where diphtheria was prevalent, had not become spontaneously immunized, but had contracted an attack of isolated laryngeal diphtheria followed by extensive paralysis, the laryngeal involvement being attributed to the fact that he was a heavy smoker.

In my patient tobacco could be excluded, and the involvement of the larynx was merely due to the natural course of the disease.

## TREATMENT OF FRACTURES OF THE CLAVICLE.

BY

H. H. GREENWOOD, M.B., B.S.LOND., F.R.C.S.,

SURGEON TO THE G.W.R. HOSPITAL, SWINDON.

In the *British Medical Journal* of April 28th (p. 723) there was a comment on the treatment of fractures of the clavicle, with a reference to modifications of the usual Sayre's adhesive plaster method. Whatever variant be employed, adhesive plaster condemns a strong hairy man to a month or so of mild purgatory, and inflicts on the more tender skin of a woman or a child an irritation that is wellnigh intolerable; over the scene of the final removal of the plaster it is better to draw a veil.

In the majority of cases of fractured clavicle the fracture is situated somewhere within the inner two-thirds. Leaving out those rare and troublesome fractures close up to the sterno-clavicular joint, and those near to the acromio-clavicular joint, which present special problems in treatment, these fractures can be adequately treated by the padded ring method. This is no new idea, but the rings which I have used for the past two years in hospital and private cases are, I believe, an advance on previous devices. The rings are made of wash-leather tightly packed with wool, and having incorporated with the wool a spring. They have been made for me by Mr. Walgrove, of 4, Hardwick Place, Harrington Square, N.W.1.

The method of application is important. The anterior strap of webbing is drawn sufficiently tight to keep the anterior part of the ring in the sulcus internal to the head of the humerus, so that on pulling back the rings pressure backwards is made on the outer fragment. The strap is fastened to the ring on each side by a stout safety-pin, and should then lie across the chest above the level of the mammae. Two straps are used behind, and are drawn up as tightly as comfort will allow; they also are pinned to the rings. Generally it will be found that on the next and

succeeding days the patient will tolerate further shortening of the posterior straps. When the rings are efficiently adjusted the arm of the affected side is placed across the front of the chest with the hand pointing towards the opposite shoulder, and loosely fixed there by any convenient method—bandage or sling. The thickness of the ring acts as an axillary pad, giving leverage outwards of the outer fragment.

I have found this method far more effective than any plaster method for the majority of cases, and as to comfort there is no comparison. In a busy out-patient department the saving of time is considerable. It is so simple that nurses quickly learn how to adjust the rings, and the patient only needs inspection by the surgeon before being allowed to go home. One young amateur jockey with a comminuted fracture found himself so comfortable that at the end of a fortnight he could ride at full gallop without discomfort—needless to say, without the surgeon's permission.

From the illustrations it will be seen that the appliance leaves free the breast in the female, neither pressing on nor irritating that organ. Usually it will be found that the most effective leverage is secured by tightening the upper strap behind, while the lower strap is only drawn sufficiently tight to counterbalance the pull of the anterior strap.

In the earlier rings made for me I tried a covering of rubber sheeting, but this soon perished; it was more expensive, it gave less secure purchase for the safety-pins, and caused unpleasant sweating in the axillae.

## PYREXIA DUE TO INFECTED DEAD TEETH.

BY

LEONARD G. J. MACKEY, M.D., M.R.C.P.,

HONORARY PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM, AND TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

The following three cases are interesting examples of a prolonged fever arising from apical abscesses, and they have several features in common—namely:

1. The fever was considerable and of long duration in each case, and terminated at once on extraction of the infected tooth or teeth.

2. In none of the cases is it known when the fever began; so it may have been of much longer duration than is shown by the charts.

3. All three patients complained only of vague ill health; they had no pain and there were no symptoms pointing to any known disease. In Case I I had the patient's temperature taken most carefully to make sure that she was not malingering. In Case II the patient protested that he felt well enough to be in his shop and resented being kept in bed. In Case III the patient refused to remain in bed after two weeks and returned to his business.

4. In all three cases the discovery of the lesion was made by a radiologist. In Case I a solitary abscessed tooth was seen by the radiologist in skiagrams taken of the nasal sinuses. In Case II the abscessed stump was completely covered by clean healthy gum. In Case III the abscessed teeth were discovered amongst several root-filled teeth by the radiologist.

It is not improbable that some of the apparently healthy possessors of abscessed teeth would prove to be running an evening temperature if they submitted themselves to the

test of the thermometer. It is also probable that a pyrexia which is attributed to the patient's illness is sometimes due to an unsuspected root infection, and that if encountered, say, after an operation, or after an attack of pneumonia, or in a person with valvular disease, it might be the cause of much anxiety to both patient and doctor.

It cannot be too frequently stated that root abscesses are quite common in the apparently edentulous, and the fact that a patient has clean empty gums does not warrant us neglecting to advise an x-ray examination of them if the patient's clinical symptoms are such as can be caused by some obscure focus of infection.

Vague ill health, brachial neuritis and sciatica, fibrositis, weakness of the heart muscle, and—may I add?—pyrexia are among the least serious consequences of root abscess.

#### CASE I.—Pyrexia for Seventeen Weeks.

The patient was a middle-aged lady whom I saw in consultation with Dr. L. Kirkby Thomas in 1921.

She had had a febrile illness for seventeen weeks, without any physical signs or symptoms that afforded the slightest clue to the cause of her high temperature, which at times reached  $103^{\circ}$ , as is shown in the accompanying chart. All the investigations usually carried out in such a case proved fruitless, including, I am ashamed to say, tests carried out at my suggestion to discover if she was malingering.

Finally, we decided to have her sinuses radiographed, and, though they proved normal, the radiograph revealed an abscess at the root of a solitary tooth.

With the extraction of the tooth on the following day the pyrexia ceased, and her health, which had been somewhat affected by her long fever, rapidly improved, and has remained good up to the present day.

The temperature chart was made by the nurses in attendance on the patient. No one knows when the pyrexia began.

#### CASE II.—Pyrexia for Six Weeks.

This patient, a middle-aged man, was under the care of Dr. G. C. Hartley, who was first called to see him in January last because the patient's wife discovered that her husband had a high temperature every evening. Dr. Hartley, finding no obvious cause for the pyrexia except a suspicious tooth, had the tooth extracted; in spite of

way; but all tests, including blood cultures and Widal and Wassermann reactions, proved negative. A radiograph of the patient's gums, however, revealed a small abscessed

CASE II.

root of which there was no part visible from the mouth. This root was extracted, and for the first time since the discovery of the pyrexia the temperature became normal. A few days later, on account of bleeding, the socket was plugged, and the temperature immediately rose again. The next day the plug was removed, and the temperature fell to normal and has remained so ever since.

The accompanying temperature chart was commenced by Dr. Hartley when the patient was in his charge, and was continued by the nurses at the Queen's Hospital. It is not known when the pyrexia began.

CASE III.

#### CASE III.—Pyrexia for Seven Weeks.

A business man, aged 47, a patient of Dr. J. M. McQueen, in September, 1927, complained of a vague ill health and loss of weight and strength. His evening temperature was found to be between  $101^{\circ}$  and  $102^{\circ}$ , but no cause for this could be discovered, nor had he any symptoms which gave any clue to the origin of the pyrexia.

The usual investigations and tests were made, but all proved negative till an x-ray examination revealed small abscesses at the roots of three root-filled teeth.

With the extraction of his teeth the pyrexia ceased and his health rapidly improved.

He reports that he has been quite well since the teeth were removed, and that there has been no further rise of temperature.

The accompanying chart is constructed from notes kept by the patient and Dr. McQueen. It is not known when the pyrexia began.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### RUPTURED MALARIAL SPLEEN: SPLENECTOMY: RECOVERY.

THE following record may be of interest since rupture of a malarial spleen in Jamaica usually causes sudden death, followed by a coroner's inquest. Moreover, the patient was not seen until thirty hours after the accident causing the rupture.

A man, aged 37, whom I had known for several years to be suffering from malaria, with a large spleen, was on August 22nd, 1926, at about 11 a.m., thrown from a "buggy," falling chiefly on the abdomen. Shortly after the accident he vomited twice; during the following night he had severe abdominal pains, and passed two blood-stained stools. He was not seen by me till 6 p.m. on the following day (thirty hours after the accident), when he was in a collapsed condition, with a pulse of 120, and complained of severe pain all over the abdomen, but most acute in the hypogastrium and right iliac fossa. The abdomen was rigid and very tender all over, with dullness in the flanks; no superficial reflexes could be made out positively.

He was removed to hospital, and at 7 p.m. his abdomen was opened through a right rectus incision. The peritoneal cavity was full of blood, for the most part dark and clotted, but there was evidence of profuse fresh bleeding. The abdominal organs were quickly examined and the spleen was found to be ruptured—

this, however, the pyrexia continued. Eventually the patient was admitted into the Queen's Hospital, and I investigated his condition in the usual

ruptures A and C (see photograph) being easily felt. This wound was at once closed with forceps and an upper left rectus incision made, but as there was some difficulty in delivering the spleen an incision was made along the margin of the lower ribs to meet it. The spleen was then easily delivered, the pedicle clamped and tied, and the organ removed. At this stage the patient's condition was so poor that after rapidly cleansing the peritoneal cavity both wounds were quickly sutured in single layers and a drainage tube was inserted into the pelvic cavity; this was removed in forty-eight hours. Saline injections were given continuously during the operation, and rectal salines for the next twenty-four hours. I find it difficult to give blood transfusions in Jamaica owing to the high incidence of syphilis and to the aversion of the natives to act as donors.

The wounds showed superficial sepsis for a few days; but for this there was an uninterrupted convalescence. The man was discharged in four weeks from hospital, apparently quite well; he has not returned to me with an attack of malaria, but reported four weeks after with an attack of gonorrhoea. The spleen weighed 16 oz. on the morning after the operation. The ruptures labelled A, B, C, D in the accompanying photograph were on the outer surface; rupture E was on the inner surface.

#### Conclusions.

The haemorrhage must have stopped temporarily, but was renewed by the jolting over a four-mile rough road to hospital. Evidently no large vessel was implicated. The two blood-stained stools may have been caused by a contusion of the bowel which did not appear on the peritoneal surface, or have been due to the common practice of the peasantry of dosing themselves with calomel to remove "bruised blood." Another notable feature of the case is the lack of shock, which I have often observed among the natives.

D. LAURENCE TATE, F.R.C.S. Ed.

Montego Bay Hospital, Jamaica.

#### PNEUMOCOCCAL PERITONITIS.

THE interesting case reported by Dr. Seymour (May 26th, p. 885) prompts me to describe another case of pneumococcal peritonitis, which eventually recovered.

A woman, aged 35, developed acute primary pneumonia involving the lower lobe of the left lung. The crisis occurred on the eighth day, with considerable collapse, vomiting, and copious evacuation of the bowels. Subsequently the abdomen became distended and a faint rash appeared on the flanks. A Widal test on the 11th day was negative. Distension of the abdomen progressed and constipation became absolute; there was no vomiting, but the tongue was very dry, and the facies was Hippocratic. On the advice of Dr. Carey Coombs, pituitrin was ordered every four hours. The patient became very collapsed after the third injection, but the bowels were opened and gradually the acute abdominal condition subsided. The temperature, however, began to rise again, and repeated efforts were made to locate a possible empyema, without success.

On the 21st day the patient became suddenly collapsed after a hard cough; soon afterwards the presence of a small quantity of fluid was demonstrated at the left base. The patient also began to cough up pus; presumably a small interlobar empyema had burst into the main pleural cavity. After this episode the patient made progress and the signs in the chest cleared up.

On the 44th day and again on the 60th day, the patient had a slight attack of intestinal colic. On the 66th day the colic recommenced, peristalsis was visible, constipation became absolute, and she began to vomit.

Mr. C. O. Bodman opened the abdomen under gas and oxygen anaesthesia. Through a median incision the small intestine was seen to be universally distended and densely matted with adhesions in the pelvis. The large intestine was not distended,

but was involved in the adhesions in the pelvis; some adhesions were soft and recent, others were tough. Numerous adhesions and hands were divided, but owing to the condition of the patient jejunosomy had to be performed.

After eleven weeks the fistula was still discharging an excoeriant fluid, so a second operation was performed by Mr. C. O. Bodman, the scar of the previous operation being excised. On opening the peritoneum it was seen that the adhesions were less numerous than on the former occasion, but the last loop of the ileum was densely adherent to the depths of the pelvis. The fistula was found to be connected with the upper end of the ileum; this was dissected away from the abdominal wall and anastomosed with the transverse colon.

The patient made a satisfactory recovery and was seen recently a year after operation; she was in excellent health and had suffered no further abdominal discomfort.

Apparently at the time of the crisis there was a peritoneal effusion which resolved, leaving in its wake a mass of adhesions; these, in course of time, contracted and caused the obstruction.

I wish to thank Mr. C. O. Bodman, honorary surgeon to the Bruce Wills Memorial Hospital, for permission to record the details of this case.

FRANK BOBMAN, M.B.,  
Assistant Physician, Bruce Wills Memorial  
Hospital, Bristol.

## Reports of Societies.

### MALARIAL TREATMENT OF GENERAL PARALYSIS.

At a special meeting of the Devon and Exeter Medical-Chirurgical Society at the Devon County Mental Hospital on May 24th, with Dr. G. G. GIDLEY in the chair, the medical superintendent, Dr. R. EAGER, opened a discussion on general paralysis of the insane, with special reference to the treatment by malaria, which had been conducted for about two and a half years at this hospital.

Dr. EAGER said that general paralysis was an organic disease of the cerebral cortex, which gave rise to motor paralysis and extreme mental deterioration; the average duration from the incipient symptoms to death was four years. At present it had to be considered incurable, although remissions might occur. Pathologically the disease was an invasion of the cerebral cortex by the spirochaete of syphilis, and, in addition to the Wassermann and globulin reactions, diagnostic importance was attached to the increased cell count in the cerebro-spinal fluid and to the colloidal gold reaction. Dr. Eager emphasized the greater incidence of the disease in the industrial centres as compared with rural areas; he cited his own experience at the Devon County Mental Hospital and the fall in the figures since cases from Devonport had ceased to be admitted. Further, the disease was almost unknown in uncivilized countries. As regards its incidence in syphilitic infection, 3 per cent. was given as the average figure for the development of general paralysis; lightning pains and ataxia were not, as a rule, concomitant symptoms. Dr. Eager then discussed the three typical stages of the disease, and showed a case under treatment at the hospital illustrative of each stage. In the first stage, that of mental exaltation, appeared the classical ideas of grandeur; this was the most hopeful period for treatment. Next came loss of initiative, when, for instance, the artist failed to secure tone for his pictures and the musician to gain his accustomed encore. Later there followed untidiness and slovenliness of habit. At this period the physical signs present were frequently inequality and sluggish reaction of the pupils; tremors of the face, tongue, and hands; and an increase in the patellar reflexes. In illustration of this stage Dr. Eager showed a man, aged 40, who, on admission, declared himself to be the Prince of Romania, and claimed a flight from Australia in three minutes. His pupils were unequal and the knee-jerks exaggerated; there were tremors of the fingers, and the tongue was protruded in the "trombone" fashion. In the second, or congestive stage, Dr. Eager drew attention to the loss of facial expression and the tendency to sit "huddled up." He showed two men in whom both characteristics were evident. Some improvement had been noted physically in these two cases after malarial treatment. In the course of the third stage, or stage of extinction, there occurred the

contractures of the limbs and a mental condition of apathy and dementia. A bed patient was carried in as an example of this stage. Dr. Eager then passed to the subject of acute delirious mania, suggesting that some of these cases may be examples of general paralysis in the early stage. It was regrettable that the violent condition of these patients on admission often made it impossible to perform the routine tests for diagnosis. Again, there might be a demented condition in general paralysis from start to finish. Reference was made to the juvenile type and the relation to congenital syphilis. Such cases occurred under the age of 20, and the patients were imbecile, although physically conforming to the adult form of the affection. In diagnosis epileptic fits were often difficult to distinguish from those occurring in early cases of general paralysis. As regards the incidence of remissions, Dr. Eager gave 4 per cent. as his own experience, but he stated that 14 per cent. had been noted in the Bethlem Royal Hospital.

Dr. C. F. BAINBRIDGE then gave an account of the experience drawn from two and a half years' trial of malarial therapy, referring briefly to the history of the treatment and to the effects of intercurrent infections, such as pneumonia and sepsis, in the causation of remissions which had suggested artificial infection. Thus typhus, relapsing fever, and typhoid fever had been given a trial. The credit for the introduction of malaria belonged, however, to Professor Wagner Jauregg of Vienna, whose first attempts meeting with disappointment caused him to give up the treatment for some years; on resumption, in 1919, the results proved more reassuring. As regards the mode of action Dr. Bainbridge said there were two schools of thought, one holding that antibodies were concerned, the other that the effects of high temperature were responsible. Although it was admitted that high temperatures were inimical to spirochaetes it would seem that antibodies played the important part in malaria therapy. There was no doubt that a great change occurred in the brain as the result of malarial infection in general paralysis. Before the treatment it had been demonstrated that spirochaetes swarmed in the cerebro-spinal fluid, but after a malarial attack there was considerable reduction and an accompanying evidence of trauma. Dr. Bainbridge mentioned that in the first instance the infected mosquitos had been obtained from the Ministry of Health, a benignant tertian strain having been required owing to the average patient being far too weak to risk infection with a malignant tertian parasite. He also explained the three methods for the introduction of the infection—namely: (1) by direct transmission from the mosquito (he exhibited the small glass container with gauge lid and small circular opening for adaptation to the thigh of the patient); (2) by injection of infected blood into the loose cellular tissue; (3) direct injection into a vein of defibrinated infected blood. The third method gave a more prompt result, but the first has been of more general use. After infection in the mosquito season the patient remained under mosquito netting for the protection of others, and a four-hourly chart of the temperature was kept. As a rule ten to twelve pyrexial attacks up to 105° F. were allowed to pass by untreated, but sponging was employed on any indication that the fever was getting beyond control. Dr. Bainbridge had observed elevations to 107° F. Having regard to the type of patient the greatest caution was necessary, not only with reference to the control of the temperatures, but also in ensuring methodical routine examinations of the heart and lungs. A careful watch was also kept for the appearance of jaundice. Quinine hydrochloride had been found to answer well in the subsequent treatment of malaria, but occasionally relapses occurred, some of which were welcomed and allowed to run a temporary course if the previous results had proved negative as regards the symptoms of general paralysis. During treatment the patient manifested physical debility, but on the other hand there was definite mental improvement. As an illustration Dr. Bainbridge mentioned the case of a man who on admission had promised to present him with a golden Rolls-Royce, but during treatment the generosity dwindled to less exaggerated suggestions, until finally, on discharge, the man appreciated his previous delusions. He was at present very cheerful,

but a little excitable, and there was some tendency to confusion of words. He had also found that, as a rule, inequality or other defects of the pupil remained unchanged, but that speech, handwriting, and gait improved. The important point was to give the treatment in the primary stage, and here there was considerable, and indeed almost insurmountable difficulty, with regard to the so-called pauper patient, who could only be admitted on certificate. In reviewing the cases treated at the Devon County Mental Hospital it was essential to remember that many of them had come under treatment by malaria infection at a late stage. Some risk seemed justifiable at the present time when there was no other known agent capable of removing or depleting spirochaetes from the cerebro-spinal fluid. The salvarsan series of drugs had been proved to be futile in this respect. Of the 21 patients treated in the past two and a half years 4 had been discharged considerably improved, 1 awaited discharge considerably improved, 10 had improved either mentally or physically, or in both respects, and 3 had died, but it was interesting to note that at the necropsy no spirochaetes were found in the brain. Of the remainder, 2 had definitely deteriorated and 1 patient was still under treatment. As a precaution all cases thus treated and subsequently discharged were notified to the respective medical officers of health in view of the possibility of latent malaria. Dr. Bainbridge concluded his address by showing three of the discharged patients benefited by malarial treatment; they admitted that their condition had been greatly improved in hospital, and were grateful for their treatment.

Dr. C. F. PATERSON, pathologist to the hospital, described the laboratory technique involved in the diagnosis of syphilitic infection of the nervous system and the more recent tests employed in the examination of the cerebro-spinal fluid. He said that in neuro-syphilis the cerebro-spinal fluid only reflected the meningeal inflammation, but since this was a frequent accompaniment of vascular or gummatous disease some alteration was usually found in the cerebro-spinal fluid; the amount of alteration had been found to vary with the degree of meningeal inflammation and with its situation. Although the final diagnosis of general paralysis often depended on the examination of the spinal fluid, it would be unjustifiable to attach value to a single examination, and a thorough examination of all the elements might merely go to prove the presence of a severe syphilitic infection. In the same way the occurrence of plasma cells and the paretic curve of Lange (held to be pathognomonic of general paralysis), might only be indicative of severe syphilitic disease of the central nervous system. In the opinion of Dr. Paterson more reliance could be placed on the colloidal tests, and more value could be drawn from the paretic curves if they remained constant after many months of antisyphilitic treatment—the opposite being noted in other syphilitic infections. The pressure in the spinal fluid would be found considerably raised in general paralysis, tabes, and in neuro-syphilis generally in the secondary and tertiary stages, but an important point in differential diagnosis was the fine fibrin web which sometimes formed, after settling for some hours, in cases of general paralysis. Again, there was an increase in the cell count in all syphilitic infections of the central nervous system, but in the case of general paralysis this increase was frequently so high as to be diagnostic in itself. Dr. Paterson added that the increased globulin finding could not be regarded as a conclusive test, but he mentioned some observations made by Dr. Eager during the war, when more opportunity was given for the investigation of early cases; these indicated that a positive globulin reaction was present before a positive Wassermann reaction developed. On the whole it was concluded that more evidence was to be obtained from the colloidal gold tests.

Mr. SHUTE of the Ministry of Health gave a short account of the steps taken to obtain a pure strain of malaria infection, and by means of diagrams and slides showed the various phases in the life-cycle of the malarial parasite as observed in the mosquito and in man.

Dr. GIMLER mentioned the somewhat unusual occurrence of a husband and wife who both developed general paralysis—the wife showing symptoms some eight years

after the death of her husband. He asked why general paralysis did not develop in all cases of syphilis.

Dr. EAGEN, replying, said he had no experience of the dual occurrence of general paralysis in a man and wife. It was possible that spirochaetal strains existed with selective qualities which accounted for the comparatively low incidence of general paralysis in syphilitic infection. He did not claim at this stage that malaria treatment was a cure for general paralysis, although striking improvement had followed such treatment in some cases, and was at present maintained.

Dr. BAINBRIDGE, in reply to a question by Dr. Fleming, stated that he had not noted hallucinations in the patients under the malaria treatment.

### TREATMENT OF HARE-LIP.

At a meeting of the Section of Surgery of the Royal Society of Medicine, on June 6th, with the President, Mr. WARREN LOW, in the chair, a discussion was held on the treatment of hare-lip.

Dr. VICTOR VEAU (Paris) said that there was always sufficient tissue present in all types of hare-lip to allow of reconstruction of the deformity. He classified the cases into four groups: (1) simple unilateral cleft, (2) total unilateral cleft, (3) simple bilateral cleft, and (4) total bilateral cleft. The first and second groups formed by far the greatest number of cases. Discussing the operative technique in the treatment of the simple type of hare-lip, Dr. Veau said that accurate suture of the muscles was the most important detail in all operations for hare-lip, since these structures gave the thickness and shape to the lip. He usually used one (or more) deep cutgut sutures for the muscles, which he had carefully defined. Attention was next paid to the muco-cutaneous junction, which he sutured very accurately with fine silk, using magnifying glasses. The speaker pointed out that the prominence of the vermilion border of the lip added very considerably to the cosmetic result. He described the incision he employed to reconstruct the "Cupid's bow." Many photographs were shown of cases before and after treatment; the results in most instances had been excellent. He mentioned that the skin sutures should not be inserted deeply, otherwise scarring was certain to occur. Dr. Veau enumerated the effects of poor operations, such as notching of the free edge of the lip, inclusion of skin in the mucous portion, and inclusion of mucous membrane in the skin region. He described operations to remedy these defects, and again emphasized the importance of suturing the muscles. In cases of unilateral total hare-lip, the speaker said that the most difficult portion of the deformity to correct was the spreading out of the nostril over the cleft. Retraction of the upper lip following treatment was very unsightly and should be prevented. He did not remove the premaxilla, but if necessary divided the bone and displaced it gently backwards. He recommended reconstruction of the floor of the nose by turning down a muco-periosteal flap from the septum together with a small flap of muco-periosteum from the palate, after cutting the frenum and stripping up the lip. After repairing the lip, he passed a deep suture through the deep aspect of the deformed ala on its outer side, under the floor of the anterior nares, bringing it out through the skin of the face just external to the normal ala and tying it there. This suture pulled in the flattened ala. The speaker showed photographs illustrating the good results he has obtained by this method. He said that the earlier the operation was performed the better was the prospect of a good nostril. He was certain that reconstruction of all the elements taking part in the production of the deformity was essential.

Mr. C. H. FAGGE classified hare-lip into three types: partial, unilateral, and bilateral. He had always found that the tissues were defective, and that even in the partial type the ala of the nose was deformed on that side. The speaker carried his incision up into the nostril, and he undercut the cheek on the outer side before suturing in order to overcome the splaying out of the nostril. A wide nostril produced difficulties in speech, and excision of a portion of the alar cartilage had not met with much

success. He said that eversion of the ala could not be corrected, and also that the apex of the nostril was usually depressed. In bilateral cases retraction of the lip presented the greatest difficulty, but an epithelial inlay and the use of a prosthetic apparatus overcame the deformity.

Mr. T. PAMFRET KILNER said that he and Mr. Gillies had had most experience of the secondary operations on cases with poor results from primary operations. He strongly recommended the simplest methods in the primary procedure, correcting all the layers concerned and reducing raw surfaces to a minimum. He had not seen good results from primary operations, and he condemned strongly all flaps and zigzag incisions. More attention should be paid to the remoulding of the nostril than to the production of an artistic vermilion border. He did not sacrifice any skin. Mr. Kilner was in agreement with some American surgeons concerning the importance of moulding the alveolar cleft by submucous wiring. This produced better contour and more regular dentition, and obviated the necessity for muco-periosteal flaps. He thought that replacement of the premaxilla should be gradually produced. He used Logan's traction bow to relieve tension on the sutures, which were removed in three to five days. Referring briefly to the secondary operations, he said that the epithelial inlay and prosthesis was the best treatment for the retracted upper lip following operations on cases of bilateral hare-lip; for readjustment of the lip he employed the "Cupid's bow" operation, excising a small area of skin and suturing the mucous membrane to the new skin edge, so producing a new and shapely muco-cutaneous junction. The nose was remodelled by fracturing the nasal bones, resetting the whole nose, and, if necessary, carrying out a cartilage graft from the ribs.

Mr. O. L. ADDISON said that the best time to operate was during the first few weeks. He thought the immediate result was a secondary consideration. There was no necessity for wiring the alveolus if the lip was sutured early, for the gap gradually closed. The speaker agreed with Mr. Fagge that there were always defective tissues present and that the eversion of the nostril could not be corrected. He disliked the method of reconstructing the anterior part of the floor of the nose, and also any attempt at filling up this gap with other structures. The epithelial inlay was an excellent method of treating the flat retracted lip.

Mr. C. W. G. BRYAN said that he operated at three to six weeks. He freed the sound side widely, moving the sound nostril inwards to help to mould the deformed side. He never sacrificed any tissue, and considered the "Cupid's bow" operation a very valuable procedure.

Mr. C. A. R. NICHOL said that he operated at two to three months, since then the tissues were stronger and a better hold could be obtained. If the child was seen early, he instructed the mother to press the projecting alveolus back several times a day. The effect was often remarkable after a month's treatment. In severe cases he fractured and wired the alveolus. He did not undercut the outer side of the cleft, only the inner; this allowed the columella to be moved inwards, and, after suturing, this was held by the fixed outer portion of the cleft. Many operations were usually necessary in order to obtain a satisfactory result, and a really good nostril was never seen after repair of the deformity.

### PATHOLOGICAL SPECIMENS.

A MEETING of the Section of Pathology of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on April 27th, with the President, Dr. T. T. O'FARRELL, in the chair.

#### Diverticulitis.

The PRESIDENT exhibited a piece of intestine which had been removed by Dr. L. G. GUINN from a man aged 57. Twelve years previously a tumour of unknown nature had been excised from the bladder, and, one year later, a faecal fistula appeared at the site of the wound over the pubes. The fistula had since alternately closed and opened, and during the last few years both urine and faeces had been discharged through it. When the patient was first seen by Dr. Guinn there were three apertures.

On cystoscopic examination the urine from the right kidney was observed to be cloudy, and there were two openings in the posterior wall of the bladder; no faecal matter exuded from these and their exact relation to the rectum could not be determined, though, on palpation there appeared to be some connexion with the right ureter. The difficulty in determining the exact condition of affairs was due to the presence of a large mass in the right side of the pelvis, which suggested the presence of a new growth of the intestine. The mass, in which was incorporated a considerable length of the pelvic colon, had been removed together with a small section of the bladder wall. An anastomosis had been made between the two cut ends of the intestine and the rent in the bladder had been repaired. The patient made an uninterrupted recovery, and since operation had passed urine and faeces in a normal manner. The resected intestine measured 11 cm. long (after fixation). When opened no ulceration was visible, but the muscular wall was very much thickened, the average depth being 1.5 cm. Transverse sections at several points showed many diverticula extending deeply into the wall, some almost reaching the outer surface. Histological sections were made of several places, but no evidence of malignant disease could be discovered. Where diverticula were present they exhibited chronic inflammation, plasma cells being abundant. Some diverticula showed no mucous lining, the lesion being represented by a narrow channel surrounded by inflammatory cells, but distinctly connected with the lumen of the bowel. Here and there were collections of inflammatory cells, representing, probably, the apices of diverticula.

#### *New Growths.*

Dr. J. T. WIGHAM showed specimens of a sarcoma of the spine in a boy, aged 8, who had been admitted to hospital on account of symptoms believed to be due to the recurrence of a tumour in the bones of the spine. One eye had been removed two years earlier for what was stated to be an angiosarcoma. There was no recurrence in the affected orbit. The condition began as a gradually increasing tumour of the upper dorsal vertebra, extending backwards as a projection of a soft fluctuating mass, and forwards into the mediastinum, causing a curvatura of the spine backwards and to the left; there was progressive paralysis extending from below upwards. The patient had no pain and his blood was normal except for anaemia; x rays showed the development of the tumour, and the soft fluctuating projections yielded no fluid. He died in a very emaciated condition. At the necropsy no tumour was found below the diaphragm. A thoracic tumour had partly invaded the lungs, but chiefly compressed them. In structure it was a small round-celled sarcoma, almost entirely composed of cells; in many places it was almost liquid, like thick cream, and sometimes bloodstained. The spinal cord was bent round a sharp angle; it was compressed and degenerated, but the tumour had not actually invaded it. It was not possible to be sure that the recurrence had actually taken place in the bones, which were greatly eroded.

Dr. Wigham showed next a tumour of the thyroid gland. He said that a gland removed from the neck had been received for investigation as to its nature. It was approximately spherical, about 2 cm. in diameter, and surrounded by firm fibrous tissue. It showed a structure of coarse, somewhat hyaline fibres, enclosing separate cells, many of which were polynuclear. A diagnosis was made that it was probably some type of lymphadenoma. Shortly afterwards the discomfort due to a swelling in the neck, which proved to be an enlarged thyroid, began to increase, and a hard, largely adherent left lobe of the thyroid was eventually removed. The thyroid itself, which clinically was undoubtedly malignant, proved to have the same structure as the gland. In many places it was more fibrous and less cellular, but a kind of capsule, which was stated to be formed from the sterno-mastoid, showed no muscle, but a more cellular structure than the thyroid itself. There was practically no glandular appearance in the tumour, and, in general, the appearance was more like a sarcoma than a carcinoma. Dr. Wigham referred to Ewing's belief that nearly all the tumours described as

sarcoma of the thyroid were really carcinomata, but added that most of the malignant tumours of the thyroid illustrated in the books of Ewing or other authors were very cellular structures, sometimes easily confounded with exophthalmic goitre, but not at all of the fibrous nature of this specimen.

Dr. Wigham also showed a fibroma of the tongue. The patient had noticed a whitish nodule on the side of his tongue. From its position and general appearance it was thought to be probably a secondary nodule of some malignant tumour, although rather hard. On removal and incision it was found to be hard, white, and sharply marked off from the surrounding tissues. It had never given pain or discomfort to the patient. On examination it proved to be a pure fibroma with hard hyaline fibres and very few cells, about 2 by  $1\frac{1}{2}$  by  $1\frac{1}{2}$  cm. in size.

Dr. LAIT exhibited specimens of a primary carcinoma of the lung in a woman, aged 57, who was admitted to hospital complaining of oedema of the left leg, a dry cough, weakness, and a gradual loss in weight. She was anaemic, and there was dullness over the front of the right side of the chest from the third rib downwards. There was slightly impaired vocal resonance over the area; The Wassermann reaction was negative. The presence of a tumour was confirmed by x-ray examination. At the necropsy a diffuse tumour was found occupying almost the entire lung; it was soft in consistency and cream-coloured. There was little fluid in the pleural cavity. The liver contained a few superficial metastases the size of peas, and the spleen had one deep-seated secondary deposit about as large as a walnut. Both suprarenal glands contained metastases, and the tumour had involved the pericardium on the right side. No tumour was found in any other situation. On laboratory investigation the tumour was found to be a primary carcinoma of the lung originating from the alveolar epithelium. In its growth it had utilized the lung stroma in a remarkable way, the tumour cells lying along the alveolar walls and bronchi, the structure of which was clearly definable. In places the growth filled the alveoli with a solid mass. Tumour cells were also found inside blood vessels. These cells were mostly cuboidal or also columnar; very often it was hard to distinguish their outlines, and this syncytial character was most marked in the section from the suprarenal gland. The etiology of lung tumours was discussed; tar taken into the lungs with road dust and inhalation of the exhaust gases from motors were mentioned as causes of the increased incidence of pulmonary carcinoma.

#### *Fractional Test Meals.*

Dr. J. J. McGRATH read a paper on fractional test meals, and showed lantern slides. In his paper he analysed the result of tests which he had personally conducted in a series of forty cases.

The PRESIDENT drew attention to the fact that test meals were untrustworthy in cases of gastric ulcer, but were reliable in cases of duodenal ulcer and of cancer.

Dr. R. H. MICKS said that test meals did not really determine the presence of a disease, but only served to withdraw hydrochloric acid from the stomach. They were, however, relatively safe as a means of making a diagnosis of oesophageal obstruction. He drew attention to the occasional disadvantage of analytical procedures, and said that in some cases the presence of an ulcer was perfectly clear clinically; it was very often possible to tell by examining the fasting juice whether the ulcer was benign or malignant.

Dr. A. DUNCAN had found Uffelmann's test for lactic acid of very little use in clinical practice, and he always used the ferric chloride test. He was doubtful if in malignant cases the presence of a small amount of lactic acid was of as much value as Dr. MacLean had implied. Considerable amounts of blood were frequently found in patients who had no ulcerative lesion in the stomach.

Dr. R. A. Q. O'MEARA drew attention to the importance of making certain that hydrochloric acid was present before starting a test meal, even a fractional one. The one-hour method was the best for diagnosis of gastric carcinoma, and it should be possible in this way to diagnose at least 80 per cent. of cases.

## Rebicus.

### EPILEPSY.

THE numerous problems of epilepsy, its nature, its varieties, and its possible causes have lately been the subject of several important contributions to the medical press, so that the English translation of Dr. MUSEKENS's well-known book<sup>1</sup> comes at a very opportune moment. British readers will be grateful for this opportunity of studying a volume which in many respects is unique of its kind.

Dr. Muskens deals with his subject on very broad lines, approaching it by way of physiological experiment on the simple myoclonic reflex. The first part of the book is devoted to a long and careful account of his studies on myoclonic reflexes and the myoclonic epileptic fits—studies in physiological experiment which throw much light on the subsequent development of the author's views on the etiology of the epileptic fit in man. The second part is concerned with the results obtained by various experimental injuries of the central nervous system in the production of epileptiform attacks. The third and largest section of the book deals with the epileptic disorders in man and their treatment. The neurologist, in perusing this section, will be struck by the evidence of the very careful and prolonged study of his patients which the author has made over a period of many years, a study which clearly entitles his views to the respect of all students of the disease. Great stress is laid on the occurrence of interparoxysmal myoclonic minor convulsions, an observation which was at one time much emphasized by Russell Reynolds, but which seems lately to have largely escaped general recognition. The value of the discussion on the more purely clinical aspects of the disease is enhanced by the details of many personal cases, which are never too long or too numerous to interrupt the general flow of the argument.

Traumatic epilepsy, with its own problems of causation and treatment, is fully described; but we are a little disappointed to find that the subject of the status epilepticus and its treatment hardly receives the detailed description which its interests and importance demand. Full details are provided for the general management and treatment of cases; generally speaking, the author's methods of treatment may be regarded as conservative. There is here little encouragement for those who claim success for any particular method of treatment—for example, by diet or protein shock or psychotherapy. A small but valuable appendix gives the composition of many of the secret proprietary remedies for epilepsy.

In conclusion, it may be fairly claimed for this volume that it represents a worthy monument of the author's personal experience and experiments, which can be cordially commended to all students of this complex disorder.

### THE ACTIONS AND USES OF DRUGS.

THE book entitled *Pharmacotherapeutics, Materia Medica and Drug Action*,<sup>2</sup> by Dr. S. SOLIS-COHEN and Dr. T. S. GITHENS, is an encyclopaedia of drug treatment whose scale may be judged from the fact that it comprises 2,000 pages and about a million words. Its aim and scope are defined in the preface as follows:

"In this work the endeavour has been made to set forth what is known of drug action—pharmacodynamics—as ascertained by exact methods of study, and to emphasize the uses of drugs that may be based thereon; but also to call attention to empirical measures not based on known pharmacodynamic data, but having reasonable evidence of usefulness. For this and other reasons the drugs here discussed have been classified according to their chief uses—in the main, a clinical classification, having in view the needs of practice, but always with due regard to chemistry and pharmacodynamics. It has been deemed wise to preface the detailed study of individual drugs and classes of drugs by the discussion of certain general principles, chiefly biologic, which may serve to guide the use of drugs not only, but of all classes

of remedial agents. In this discussion are included certain aspects of the newer developments in physics and chemistry; and stress is laid not only upon the adjustive and adaptive powers constituting the self-defence of the organism, but also upon the monodynamic conception of disease recovery; that is to say, the view that disease and recovery are not separate states or opposing forces, but one continuous, albeit complex, process, in which derangement and restoration are from the first associated."

In the space at our disposal we can only indicate the main features of a work planned on such comprehensive lines. Its general arrangement is as follows. The first quarter is devoted to a discussion of the general principles of drug treatment, with information regarding the sources of drugs, their standardization, and so forth. The remaining three-quarters give a systematic account of all the drugs used in medicine that are of any importance. Medicaments are divided into three main orders: (1) "antipathogens"—that is, all the drugs used to combat invasion of the body by micro-organisms and other parasites; (2) "tissue alterants," a term which includes demulcents, rubefacients, irritants, caustics, etc.; and (3) "function modifiers," comprising all drugs used to influence the functions of the body. In the case of each drug its history, chemistry, materia medica, pharmacology, and therapeutics are described.

The chief impression produced by a rapid glance through the volume is one of admiration for the immense industry of the compilers—industry of a type that hitherto many had thought to find only in Germany. Detailed study of a few sections chosen almost at random confirms this feeling of admiration; for the authors give a very full account of modern views regarding the pharmacology and therapeutics of each drug. It is indeed a remarkable achievement to have produced so large a work and to have kept the whole of it up to date. Only a small proportion of the space is occupied by details of materia medica, and most of the text is devoted to a summary of the information available concerning the therapeutic actions of drugs. The size of the book is indeed a testimony to the very large amount of pharmacological knowledge that has been accumulated, and it is interesting to note how large a proportion of the work referred to is of recent date.

The volume appears to be an excellent work of reference on drug treatment, which should prove of great service to the medical profession, since it includes within a single cover masses of information that have hitherto been difficult to obtain except from monographs. It is a book that can be recommended to all medical practitioners who wish for a full and detailed guide to modern drug therapy. Unfortunately no references are given, but the inclusion of any effective bibliography would have swelled the volume to an unmanageable size. As it is, the publishers are to be congratulated on having compressed such a large amount of printed matter into a single volume of reasonable bulk and weight; this has been achieved by the use of thin paper. In conclusion, we may say that the price (three guineas) seems very reasonable for a work of such dimensions.

### LARYNGOLOGY.

IN the third edition of his book on *Diseases of the Larynx*,<sup>3</sup> for several years out of print, Mr. BARWELL has included chapters on the trachea, bronchi, and oesophagus, and endoscopy now finds an established place. The twenty-one years which have elapsed since the first edition was published have been a period as full of progress in laryngology as in any other branch of medicine. The development of endoscopy, which has reached the stage of definite routine procedure, is largely, but not wholly, responsible for this. The management of cases of laryngeal tuberculosis is now very different, and there has been advance in the control of malignant disease in this region. All this is fully described in Mr. Barwell's book, and in consequence the whole outlook is changed. Nevertheless, he never loses sight of the fact that laryngology is based on the examination of the larynx by the indirect method with the laryngoscope.

Textbooks on diseases of the larynx usually include also

<sup>3</sup> *Diseases of the Larynx*. By Harold Barwell, M.B.Lond., F.R.C.S. Eng. Third edition. Oxford Medical Publications, London: Milford, Oxford University Press, 1926. (Demy 8vo, pp. xv+278; 112-figures. 12s. 6d. net.)

<sup>1</sup> *Epilepsy*. By L. J. J. Muskens, M.D. of Amsterdam. Foreword by Sir Charles S. Sherrington, O.M., G.B.E., M.D., F.R.S. London: Baillière, Tindall and Cox, 1928. (Roy. 8vo, pp. xiv+435; 54 figures. 25s. 6d. net.)

<sup>2</sup> *Pharmacotherapeutics, Materia Medica and Drug Action*. By Solomon Solis-Cohen, M.D., and Thomas Stetebury Githens, M.D. New York and London: D. Appleton and Co. 1928. (Med. 8vo, pp. xv+2009. 65s. net.)

descriptions of diseases of the nose and pharynx, so that the limitation of this work to the larynx and the adjacent regions which can be explored by the endoscope presents an unusual feature. It is, however, justified by the peculiar methods of examination just mentioned, which require much patience and long practice before the skill of a master is acquired, and of necessity relegate the treatment of serious disease to the hands of relatively few. If further justification were needed it is to be found in the presentation of his subject by the author, who has spared no pains to render his account complete and to provide the most recent information. He is even capable of being in advance of time, for he refers to "the late J. W. Bond": Dr. Bond is happily still with us.

Mr. Barwell has taken as much trouble to provide suitable illustrations as he has to perfect the text, and his book reflects admirably the advance of laryngology.

### INFANT NUTRITION.

THE latest addition to the by no means small number of books on the subject of infant feeding has several claims to special consideration, and in *The Principles of Infant Nutrition and their Practical Application*,\* by Drs. K. H. TALLERMAN and C. K. J. HAMILTON, will be found a very successful attempt at approaching the problems of infant feeding from the physiological point of view. It is only with a sound knowledge of the normal digestive processes of the baby and its nutritional requirements that the practitioner can look after a "feeding" case, and this book should greatly assist him. Beginning with chapters on these fundamental subjects the authors go on to discuss breast-feeding and the disorders likely to arise, with their treatment. Next comes a very good chapter on the premature infant, and then the authors open the large subject of artificial feeding. Here the arguments for and against certain special forms of feeding—such as with lactic acid milk, alkaline additions to the milk, protein milk, etc.—are set out, and the use of these various modifications is well shown in the next chapter on the nutritional disorders. In conclusion, there is an appendix giving details of certain methods of preparing feeds. An elaborate table enables the quantities of milk, water, and sugar in a milk mixture to be easily calculated. Each chapter is followed by an extensive bibliography, very carefully compiled. The authors are to be congratulated on producing a book on this subject which keeps to the fundamental and general principles without advocating any one path to success with the difficult infant. It should prove of value to the student and practitioner, and also to the specialist in this branch of medicine, especially on account of its extensive bibliography.

### DISEASES OF THE HAIR AND SCALP.

THE *Treatise on Diseases of the Hair and Scalp*\* by Dr. DANA HUBBARD is a sound and almost an exhaustive handbook of the subject. The author has not confined himself to conditions which are peculiar to the region under consideration, but has also included a discussion of such conditions as syphilis, lupus, eczema, etc., which only incidentally affect it. He begins with an account of the anatomy of the scalp—mostly, it appears, derived from that given by MacLeod—followed by a chapter on the physiology and racial peculiarities of the hair. While his account of diseases of the scalp is adequate, it does not differ materially from the chapters on the subject to be found in many good textbooks of dermatology, and there is nothing particularly novel in the therapeutics recommended. But Dr. Hubbard goes far beyond these commonplace matters. He is not afraid to invade the regions where fashion reigns, to advise on the style of hairdressing best suited to his feminine clients, even to sum up the arguments for and against bobbing, and to indicate a strong personal preference for long hair. Dr. Hubbard

has had the advantage of being associated during many years with the public health service of New York, and his work is influenced in many directions by this association. It appears that in New York all barbers' shops, hairdressing establishments, and beauty parlours are registered, are compelled to conform to certain articles of the sanitary code, and are periodically visited by sanitary inspectors to see that they do so. If they do not they are liable to be struck off the register and debarred from trade. Dr. Hubbard prints the articles of the sanitary code which are applicable in this connexion, and we are bound to admit that they are very sound, and it would be greatly to the public advantage if similar measures were adopted in this country. The employment of x-rays is likewise subject to supervision by the Public Health Department, and the sanitary code provides for the safety both of the operators and of the patients by strict regulations, which have to be observed by all practitioners, whether duly qualified medical men or not. Moreover, every place where x-rays are to be used has to be specially licensed. One very wise provision is to the effect that no licence will be granted for a basement, and great stress is laid on efficient ventilation. Again we have to confess that similar action on the part of the sanitary authorities would be most beneficial here; there are no doubt many x-ray workers whose health is jeopardized by the conditions under which they have to work, although some improvement has lately been brought about by the inspectors of the National Physical Laboratory, who will always report on an x-ray installation if requested to do so. Hospital authorities frequently follow their recommendations. But in these matters it is not sufficient to rely on voluntary effort. For these reasons, as well as for its other merits, we hope that Dr. Hubbard's book will be widely read in this country. It is attractively written and well produced.

### HOW TO START IN GENERAL PRACTICE.

A good deal of attention has been devoted during the last few years to the steps which should be taken for the instruction of senior students or newly qualified practitioners in medical ethics, including under this term the duties which devolve upon practitioners in relationship to the State and on the methods and relationships of private medical practice. It is no doubt true that such instruction can, on the whole, best be given orally, in a series of lectures or talks to senior students, especially if these are undertaken by carefully chosen persons who have themselves had experience of the things they are to talk about, and if ample time is allowed for specific questions to be raised by the students themselves. By way of supplement to such instruction, or in its absence, a handy guidebook can be of great use, and such a serviceable manual is *How to Start in General Practice*,\* by Dr. Isaac G. Briggs. Its contents are confined strictly to the field indicated by its title. It has nothing to say with regard to special branches of practice, nor, except very incidentally, with rules of ethical professional conduct or with the duties of a practitioner in relation to the community. It might indeed, with advantage, have included a chapter on the possibilities and conditions of part-time employment of a general practitioner in connexion with the school medical service, and with maternity and infant welfare clinics; for such appointments can sometimes be obtained at an early stage of the practitioner's career, may be very interesting in themselves if the duties are seriously undertaken and conscientiously carried out, and may constitute a very welcome source of auxiliary income. The book is severely practical and has but little claim to literary merit. This is, no doubt, designedly so, for though its extreme detail occasionally seems to savour of advertisement, it is true that there is little use in telling a beginner to obtain a book or account form, a piece of furniture, a drug or instrument of such and such a kind, unless he is also told exactly where he can obtain it. In these matters the book is full of information, and even though methods of fitting up a consulting room or dispensary, or of keeping records and accounts differing from those described may be

\* *The Principles of Infant Nutrition and their Practical Application*. By K. H. Tallerman, M.C., M.D. Cantab.; M.R.C.P. Lond., and C. K. J. Hamilton, M.C., B.M.Oxon, M.R.C.P. Lond. London: W. Heinemann (Medical Books), Ltd. 1928. (Demy 8vo, pp. vii + 183. 10s. net.)  
\* *A Treatise on Diseases of the Hair and Scalp*. By S. Dana Hubbard, M.D. London: H. Kimpton. 1928. (6 x 9½, pp. xv + 500; 77 figures, 4 plates. 25s. net.)

\* *How to Start in General Practice*. By Isaac G. Briggs, M.R.C.S., L.R.C.P. London: J. Murray, 1928. (Cr. 8vo, pp. ix + 158. 6s. net.)

preferable in particular practices, the advice given is invariably sound and valuable, and such advice must necessarily be based upon personal experience. Especially helpful for the newly qualified practitioner are the chapters on "purchasing a practice" and "building a new practice"; many difficulties will be avoided if he follows the detailed advice therein given. It may, however, be doubted whether it is always wise to consult a local dentist, or even the local British Medical Association secretary, with regard to the character and suitability for purchase of an individual practice, even though such inquiries are made with the permission of the vendor. Nor are we sure that it is always best, during the period of introduction, for the purchaser to "bear all expenses and receive all profits, paying the vendor the locum fee usual in the district." The advice, in a later chapter, to plan to do for oneself many of the simpler forms of laboratory investigation is, on many grounds, very wise, though commonly neglected. An excellent principle for general guidance is laid down by Dr. Briggs in the sentence: "Your patients are your guests: make them at home." On the other hand it may be that he goes too far in underestimating his guests when he says, in a warning to the beginner against explaining too much, "There are no intelligent patients."

### THE PROCESS OF EVOLUTION.

Nothing gives thoughtful men more encouragement than to see a demand for small books which handle serious subjects, such as those of the To-day and To-morrow Series. Dr. RUSSELL BRAIN has written for this series a readable and brilliant essay on a neglected aspect of evolution. He accepts the theory of evolution as the only explanation of the world of life, but believes we are still ignorant of the biological processes which bring about the transmutation and transformation of species. In this all who have examined the writings of Lamarck and of Darwin will agree. "Those who object to neo-Darwinism," he writes, "on the score that it does not explain the facts, maintain that the simultaneous and harmonious adaptational transformations required of evolution could not possibly be produced by haphazard mutations in the time available." To account for the evolution of man's posture thousands of structural units have to undergo a correlated change at the same time—a possibility outside the bounds of chance. Dr. Russell Brain is therefore of opinion that Lamarck's conception, which was also Darwin's, must be true, and that a way will yet be discovered of showing how functionally wrought modification can become hereditary. The school known as neo-Darwinists has thrown this part of Darwin's theory overboard. Dr. Russell Brain contends it must be restored; otherwise Darwin's theory is devoid of a "creational machinery."

### NOTES ON BOOKS.

In his monograph on the three-gland theory of urinary secretion<sup>1</sup> Professor PÜTTER discusses the question, not from the experimental point of view, but from a comparative study of excretory processes in general as exhibited in the animal series. His investigations lead him to the conclusion that the renal function in man is best explained by regarding the kidney as a complex of three glands. The primary functions of the kidney being the removal of the end-products of metabolism, of water, and of salts, he finds that in fishes and in many worms these functions are subserved by cells of a single type, while in the ascending animal scale there is a gradual separation of functions, so that in mammals two distinct structures are differentiated for the excretion of the end-products and water respectively—namely, the convoluted tubules and the Malpighian corpuscles. Further, there develops in mammals, in close relationship with these two glands and from small beginnings, a structure, which is also represented in amphibia—namely, the narrow limb of the loop of Henle. In this it is probable that sodium chloride and water are to a certain extent resorbed, a function analogous in a minor degree to that sub-

served by the cloacal mucous membrane of birds and many reptiles. A third element becomes differentiated in mammals in the form of the thicker distal limb of the loop of Henle; this is called the "salt-gland" by the author, its function being, in his opinion, to discharge the salts of the alkaline metals in a state of high concentration. The second—distal—group of convoluted tubules present in the human kidney are considered to have a function similar to that of the proximal group, although there is probably some differentiation, at present unknown.

Dr. GEORGES GIREL has prepared an account of the treatment of epithelioma of the skin and mucous membranes<sup>2</sup> according to the method of radiotherapy introduced by Dr. J. Coste, in which use is made of the less penetrating rays, no filtration is employed, and a strong dose is given at a single application. Dr. Girel discusses the mode of action of the longer wave-lengths on the tissues, and the histological appearance of the various tumours so dealt with. He describes in detail the technique he employs, and shows how a relatively simple form of apparatus is sufficient. A good bibliography is appended, and the book will, we think, be welcomed by those interested in this particular branch of radiotherapy.

The handy guide to *Mosquito Reduction and Malarial Prevention*,<sup>3</sup> by Drs. J. A. CRAWFORD and B. S. CHALAM, medical officers in charge of antimalarial measures in India, was reviewed in these columns (1927, i, 881) less than a year ago, and has now passed into a second edition. The authors have now added an appendix on Paris green (aceto-arsenite of copper), which, when scattered on the surface of water, is swallowed by the anopheline larvae and poisons them. It is insoluble in water, does not damage fish, aquatic insects, or ducks, and is diluted with fine road or clay dust. The mixture of 1 part in 100 must be kept dry, otherwise it will sink. Modestly introduced, this is a very useful book for malarial inspectors and managers of tea gardens, as, indeed, the rapidity with which a second edition has been called for would tend to prove.

To the "Notable British Trials" Series has been added the *Trial of Samuel Herbert Dougal*,<sup>4</sup> which contains the story of what was commonly known at the time as the Moat Farm murder. As the evidence which led to the conviction and execution of Dougal was largely circumstantial, and as the body of his victim was identified mainly by her apparel, there is not much of medico-legal interest in the trial itself. The main features from the medical aspect are probably the psychological studies exemplified by Dougal, whose career as a criminal and a ruthless woman-hunter was really remarkable, and by Camille Holland, who, at the age of about 57, after an almost austere life, yielded herself to Dougal and met her death at his hands. The strange association between this murderer and his victim is handled with considerable skill in the introduction by Miss TENNYSON JESSE, the editor of the volume.

A further edition of *How to Become a Nurse*<sup>5</sup>—the eleventh to be published since this useful little book was first produced under the editorship of the late Sir HENRY BURDETT in 1899—has appeared, incorporating the most recent information available on the subject covered by its title. The introductory chapter contains much sensible advice to would-be nurses, while the greater part of the book consists of a directory of hospitals, etc., in Great Britain and Ireland, with details of nursing salaries, terms of engagement of probationers, and status as training institutions.

In *Humanity and Labour in China*<sup>6</sup> Dame ADELAIDE ANDERSON describes a visit she paid to that country during the years 1923 to 1926, in the course of which she made a very careful investigation of industrial conditions generally. A considerable amount of information about different phases of Chinese life is set out in an interesting manner, and her discussion of such questions as child labour and the general progress of industrial reform in China is illuminating. The book is also attractive as a travel diary, and there is a pleasant description of the country through which she passed.

## THE INTERPRETATION OF GASTRIC SYMPTOMS.

ABSTRACT OF THE CROONIAN LECTURES DELIVERED BEFORE THE  
ROYAL COLLEGE OF PHYSICIANS OF LONDON,

BY

CHARLES BOLTON, C.B.E., M.D., D.Sc.LOND.,  
F.R.C.P.LOND., F.R.S.,

PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

### LECTURE I.

AFTER a short survey of the views that had been advanced by older writers, Dr. Bolton said that the conception of dyspepsia had returned to that of two hundred years ago, and that it was now widely regarded as signifying a group of symptoms resulting from functional disturbance of the stomach as a primary affection or due to organic disease; and the leading idea to be kept in mind in investigating cases should be the exclusion of organic disease. The first object in diagnosis was to ascertain the part of the gastric mechanism that was upset and the disturbance in action that it showed, and then to discover the cause of the disturbance. A thorough examination of the symptoms of the patient afforded the earliest and most delicate index of this disturbed action. Neglect of this was the greatest source of danger of missing serious organic disease. Although at first sight the varied symptoms of which patients with dyspepsia complained might seem to defy classification careful observation showed that there were several different combinations constantly recurring, and he believed it possible to classify dyspepsia into such symptom-groups, to explain them in terms of physiology, and so to build up a rational pathological physiology of the stomach.

The observations recorded were based on a series of 1,009 cases, but before proceeding with their analysis it was necessary to explain his views on the mechanism of the production of pain. Modern research had shown that the symptoms of dyspepsia were not due primarily to alterations in the chemical process of digestion but to alteration in the motor functions; and it was now generally agreed that visceral symptoms were in general almost entirely muscular in origin. The muscular sensations might be grouped as (1) minor sensations—for example, the feeling of tightness, fullness, or vague discomfort, etc., (2) pain of varying degree; there was no real difference between the two, the sensations sometimes passing on to pain or alternating with it. Both were due to excessive muscular tension, which was the resultant of two forces—stretching and muscular contraction. Normally great variations in contraction tension did not occur, and Sherrington had explained this by demonstrating the ability of the muscle to lengthen and shorten without apparent alteration of the contraction tension. The mechanism on which this postural activity depended, however, might be interfered with, and the most important cause of such interference was irritability of the neuro-muscular mechanism; sensitiveness of the nervous system varied in individuals, and was a large factor in the production of pain.

Local pain undoubtedly occurred; the minor sensations, when exaggerated into pain, were certainly examples of local pain, but although local pain originating in the oesophagus was fairly well localized, local gastric pain was, as a rule, too diffuse to be very helpful. Referred pain, on the other hand, was of much greater importance, because it was the chief gastric pain, and the position was constant and localized. In analysing his cases he had found that the areas of cutaneous hyperaesthesia mapped out by Head were of little help, as they were uncertain and irregular in occurrence. He divided the body into areas separated by transverse lines; the sternal region, extending from the root of the neck to the ensiform cartilage, represented the oesophagus, and was subdivided by a line across the fourth costal cartilage into upper and lower sternal areas. The area between the ensiform and the umbilicus he called the sterno-umbilical region; the transpyloric plane joining the ninth costal cartilage cut across the centre of this area, which could be subdivided into upper, middle, and lower

sterno-umbilical regions. Classifying the 624 cases of his series which showed pain in one area only, according to the site of pain, there were:

#### Sternal region:

Upper, representing upper oesophagus ... 53 cases  
Lower, representing lower oesophagus ... 119 "

#### Sterno-umbilical region:

Upper, representing body and stomach... 223 "  
Middle, representing pylorus ... 152 "  
Lower, representing pylorus ... 77 "

The mechanism of the stomach was likely to be upset at the time at which it was subjected to the greatest stress; the oesophagus and body were therefore likely to be disturbed at an early stage during filling of the stomach, the pylorus at a later stage during emptying. If, therefore, pain in these areas really represented disturbances in the corresponding parts of the stomach it should be possible to correlate the position of the pain with the time of onset after a meal. The following figures showed that this was the case.

		Symptoms occurring	
		Early.	One hour or later after food.
Upper sternal	...	66.6%	12.5%
Lower sternal	...	30.1%	38.4%
"	...	27.8%	47.3%
"	...	12.8%	74.4%
"	...	2.7%	90.1%

It was therefore justifiable to conclude:

- (1) That pain occurring in the upper sternal region usually came on at once after food or irregularly, and was associated with disturbance of the upper oesophagus.
- (2) That pain in the lower sternal region came on at once or late, and was associated with the lower oesophagus.
- (3) That pain in the upper sterno-umbilical area was associated with the body, and might come on early, but more often late.
- (4) That pain in the middle and lower sterno-umbilical areas was associated with pyloric disturbance, and usually came on two hours or more after food.

There was another feature of gastric pain, and that was its tendency to shift forwards as the disease proceeded, and so to appear sooner after a meal than was originally the case. Although this was most noticeable in cases where pain first appeared late it was also to be noticed in all types of case, and in severe cases the pain might eventually become constant, the patient being free from pain only in the early morning before food was taken. This was due to an increased irritability of the neuro-muscular mechanism of the stomach. The normal muscular response of the stomach to food was dependent upon a nervous reflex, which with constant irritation responded more and more easily, until in severe cases the mere presence of food, however mild, would excite the abnormal movements responsible for the symptoms. The oesophagus and body of the stomach were liable to develop early and constant pain, not only in virtue of their position and functions, but also because they were better represented in the central nervous system and were more subject to its influence. This view was supported by analysis of the cases of irregular pain, which was more commonly due to disturbance of the body or oesophagus than to that of the pylorus. Pain coming on irregularly, either early or late after food, was equally distributed between the cardiac and pyloric ends, and sometimes depended on the particular meal taken; pain occurring at any time, either day or night, was certainly much more frequently associated with body and oesophagus, and was often caused by increased pressure due to posture in an irritable stomach (straining, stooping, lying down, etc.), and above all to emotional disturbance. Constant pain, even with a presumably empty stomach, was characteristic of a high degree of nervous instability of the stomach, particularly affecting oesophagus and body. Pain in the back, if present, was usually at the same level as that in the front or higher up; oesophageal pain extended from top to bottom of the scapulae; pain associated with the body from the sixth to the tenth dorsal spine; and pyloric pain from the eighth dorsal to the second lumbar spine. Localized points of pain occurred in two areas: (1) opposite the ninth costal cartilages, more frequently on the right side than the left, and pain appeared late and was associated with the pylorus; (2) over the nipple region, usually on the left side and indicating oesophageal origin.

## LECTURE II.

Pain occurring in multiple areas was more difficult to classify, but the points were worthy of notice. The pain frequently began simultaneously in all positions, and when this happened the time of onset might be taken as indicating the origin, as in the single pain areas. The pain also often spread upwards or downwards during digestion. Upward spread usually meant a primary pyloric disturbance, whereas rapid downward spread usually pointed to considerable nervous instability.

*Sensation of fullness*, although primarily a symptom of body disorder occurring in 90 per cent. of cases with pain at the cardiac end, was found also in 80 per cent. of cases of pyloric pain. This was easily to be understood; the sensation depended on the volume of the gastric contents; if the irritable pylorus held up the gastric contents a sensation of fullness would result; if, however, the pyloric irritability showed itself late, when the contents had largely left the stomach, the sensations produced were those of hunger. Absence of pyloric relaxation was not necessarily accompanied by pyloric pain, as this only occurred when the pylorus or adjacent part of the vestibule became spasmodic, so that there was yet a third type of pyloric irritability, which was associated with the sensation of fullness but without pyloric pain. There was no doubt that these pyloric types constituted the most important group of sufferers from dyspepsia.

*Relief of Pain.*—The symptoms of functional disorder of the stomach occurred at different phases in functional activity, and ceased when the work of the particular part affected was finished. Factors causing the disappearance of pain were therefore as important as those causing it in explaining the mechanical disorder giving rise to it. Three common ways of obtaining relief were by food, by eructation, and by vomiting. Of the cases which were completely relieved by food more than half fell into the group of pyloric pain (mid and lower sterno-umbilical areas); but on analysing the time of onset it was found that in the large majority of all cases where pain was completely relieved by food the pain appeared late; so that it was probable that even those cases in which the pain was located in the cardiac or oesophageal areas were mostly secondary to a primary pyloric disturbance. On the other hand, patients who were not relieved by food were mostly the subjects of early and irregular pain. Two factors were involved in the causation of cardiac pain—the irritant nature of the gastric contents and an overaction of the neuro-muscular mechanism. The taking of food brought into play the mechanism for inhibiting muscular movements seen during normal filling of the stomach; this inhibition was naturally less effective in cases where the central nervous system was unduly irritable, and as it was the primary cardiac and oesophageal cases in which such irritability was most common, these were naturally the cases that showed least relief by food. On the other hand, the irritant nature of the gastric contents tended to exhibit itself chiefly during the later stages of digestion, when the more digestible portion of the meal had been allowed to leave the stomach; in these cases food diluted the residual contents of the stomach, and gave relief by increasing the bulk and also by diluting and neutralizing the free acid if present.

*Eructation of gas* was so constant a symptom as to be of little diagnostic help; the gas was practically always air swallowed with food, with saliva, or voluntarily; it did, however, indicate, when excessive, an unstable nervous system. Eructation of fluid was much less dependent on the nervous system, and gave some help. On the whole, acid eructations were associated more commonly with pyloric cases, and bitter or tasteless eructation with cardiac or oesophageal cases. The distinction was due to the fact that in the former group the function of the pyloric sphincter as a regulator of gastric acidity was interfered with, and hyperacidity of the gastric contents resulted.

*Vomiting.*—Nausea occurred so irregularly and in such a multitude of conditions as to be of little diagnostic importance. Vomiting, however, was of the greatest importance; it occurred in 22.8 per cent. of the whole series of 1,009 cases, and was therefore much less frequent

a symptom than pain, and indicated a high degree of irritation of the stomach. To assess its significance it was essential to take careful note of its origin and onset, for the reflex tended to become more excitable, and the vomiting then lost its initial character. It was also frequently induced by reflexes from all parts of the body, by affections of the central nervous system, and by blood poisons, so that the indications of a gastric origin required close attention. It occurred in about the same proportion of cases in the pyloric and cardiac groups, but much less frequently in the oesophageal group. The main cause of vomiting was pain. In 63 per cent. of his cases which showed vomiting the act occurred at the height of the pain, and in these there was rather a higher proportion of pyloric cases than cardiac; oesophageal pain was the least likely to cause vomiting. The next most active cause of vomiting was regurgitation of fluid from the stomach to oesophagus; 11.7 per cent. of the cases were due to this cause. The regurgitating fluid irritated the fauces and caused retching; this condition was found much more frequently in oesophageal cases, and was especially common in neurotic subjects. The third cause was the voluntary one in which the patient made himself vomit to relieve his symptoms. Sometimes the habit was continued as an involuntary one, and the patient then complained of it as his chief symptom. This group contained but few with oesophageal symptoms. These three factors—pain, regurgitation of fluid, and voluntary vomiting—accounted for 85 per cent. of his cases.

*Wasting* was an important symptom in cancer and pyloric obstruction, and also in certain remote diseases with gastric symptoms. Functional disturbances of the stomach, including uncomplicated ulcer, did not cause wasting; but this symptom might be associated with it in three conditions: (1) severe vomiting, (2) voluntary reduction of food to relieve symptoms or because the patient was afraid to eat, (3) loss of appetite with nausea. All these were indications of a neurotic individual. The wasting impaired the nervous system, and symptoms were aggravated.

*Appetite* was good in most of the pyloric cases; these included the most robust individuals and contained the smallest number of neurotics. Among cardiac and oesophageal cases about half had a fair or poor appetite.

*Sex of Patient and Shape of Stomach.*—In males the pyloric region was affected twice as often as the body; in females the pyloric region and the body were affected to an equal degree. With regard to shape of the organ it was not justifiable to look upon any form of dyspepsia as due to any particular shape of stomach. Normal individuals varied about a certain average as regards position and shape of stomach, and also as regards each of its functions; the type of stomach affected must produce some modification in the processes resulting from any disturbance, but all people, whatever the sex or the shape of the stomach, were liable to the same affections, and any differences in individuals in liability to any particular affection depended on the make-up of the nervous system and the habit of the individual. The greater nervous tendency of the female was shown by comparing the two sexes as regards the time of onset of symptoms; the female showed in every position of pain a much greater tendency than the male to feel the pain quite early.

*Organic Lesions.*—Gastritis and uncomplicated ulcer were the only two organic lesions that need be mentioned. Gastritis was present in some degree in all chronic ulcers, but if it produced any symptoms they were indistinguishable from those due to irritability of the body of the stomach, except by the type of vomiting and examination of the gastric contents. Ulcer, on the other hand, was of great importance for the present purpose because we knew the position, and could therefore locate the irritable focus producing the symptoms. Duodenal ulcers must be considered with gastric ulcers, as whichever side of the pylorus the ulcer was situated the effect on the pylorus was the same. In duodenal ulcer 87 per cent. of cases of isolated pain exhibited pyloric pain, 12 per cent. showed cardiac pain, whilst in exceptional cases there was no pain, but merely a sensation of fullness and regurgitation. This entirely agreed with

the conception of pyloric irritability previously described. Of 59 cases of gastric ulcer 23 were found by the surgeon to be pyloric and 36 in the body; in the pyloric group there was pyloric pain in 88.8 per cent., whilst in the cardiac group there was pyloric pain in only 40 per cent. and cardiac pain in 60 per cent. That a certain number of ulcers of the body caused cardiac pain had been noted by various people, the explanation being that an ulcer on the lesser curvature in the vestibule might give rise to irritability of the pylorus through the myenteric plexus. These results indicated that the pain in ulcer was not produced by irritation by gastric contents of afferent nerve fibres in the base of the ulcer, as in that case the referred pain should always indicate accurately the position of the ulcer; rather the pain indicated the segment of the stomach irritated. Duodenal and pyloric ulcers acted as a focus of irritation to the pylorus with secondary cardiac symptoms, so that the pain was usually pyloric and only occasionally cardiac. Ulcer of the body irritated the cardiac portion and pain was usually cardiac, but in a smaller proportion might by its position irritate the pylorus and produce pyloric pain. The pain of ulcer was thus of precisely the same nature as that of functional disturbance, and it obeyed the same laws, so that it was impossible to separate them clinically.

*Reflex Effects on the Stomach.*—Our knowledge of reflex dyspepsia as a result of disorder to some other organ was fragmentary, but from a clinical point of view the most important sources of origin of such reflexes were the biliary apparatus and intestines. With regard to gall-stones, he had found that in a series of 59 cases that had been operated upon the greater number suffered from gastric symptoms originating in the body; this agreed with general medical opinion and was in conformity with a number of observations recorded on the gastric acidity in gall-bladder conditions. It was much more difficult to come to any conclusion on the question of reflex irritation from the intestine; but, with regard to appendicitis, he agreed with those who held that chronic appendicitis did not exist except as the end-result of an acute attack. In a series of cases of appendicectomy for gastric symptoms in which removal of the appendix produced no effect, an analysis of the position of the pain gave results not unlike those in whom operation had been postponed for a supposed but non-existent ulcer.

### LECTURE III.

The symptoms of functional disorder of the stomach could thus be classified into three groups or syndromes: pyloric, cardiac, and oesophageal, each connected with a different part of the gastric mechanism; it remained to consider what alterations in the mechanism were responsible for the production of these symptom-groups and the cause of those alterations.

#### *Pyloric Syndromes.*

The causes of these were: (1) Indigestible and irritating food; the function of the pylorus was to hold up portions which required further disintegration, so that these irritants led to deficient pyloric relaxation. (2) Hyperacidity of gastric contents, which resulted from delayed pyloric relaxation itself, maintained the irritability, and induced spasm. The facility with which these two causes produced their effect depended upon the stability of the nervous system, which might be affected adversely by (1) a direct effect upon the myenteric plexus by a chronic ulcer or very rarely by cancer; (2) by reflex irritation from elsewhere in the alimentary system; and (3) general conditions, such as neurasthenia, although these produced their effect most often in the other syndromes.

Effects of the pyloric irritability were the same whatever the cause: the pylorus was interfered with in its double capacity (1) as a regulator of the output of food, and (2) as a regulator of the acidity of the gastric contents. The pyloric sphincter determined the rate at which food left the stomach; at the beginning of digestion it relaxed enough to allow liquids and finely divided solids to pass, other material being shot back into the pyloric vestibule for further disintegration; the gastric contents thus became more irritating as digestion proceeded. If indigestible and

irritating food were taken the factors bringing about pyloric relaxation became less effective, the pylorus refused to relax, and finally became spasmotic; peristalsis then increased in vigour, as in the case of all opposed muscles, so that the internal pressure was raised. If when the spasm came on the greater part of the food had left the stomach the exaggerated movements of the stomach were of the same nature as the normal hunger contractions of the empty stomach, and pain was blended with the sensation of emptiness or hunger. If the gastric contents at the time of pylorus spasm were considerable the pain was associated with a feeling of fullness. As the cardiac sphincter relaxed there might be occasional regurgitation of acid fluid into the oesophagus, with a burning sensation in the throat, and the fluid might reach the mouth and be spat out. As the second function of the pylorus in regulating the acidity of the gastric contents by permitting the regurgitation of alkaline duodenal contents had recently been denied, it was necessary to give a brief description of the foundations on which this idea was based. Beaumont was the first to recognize bile in the stomach, but no attention was paid to it until Boldyreff clearly established the spontaneous regurgitation of bile and intestinal juices into the empty stomach of both dog and man. Boldyreff proved conclusively that if acid were introduced into the stomach it was neutralized by regurgitation of pancreatic juice; he thought the process of regurgitation neutralized the gastric contents down to 0.15 per cent. as the optimum acidity for digestion by trypsin. That this neutralization also occurred as a normal process in the digesting stomach in man had later been demonstrated by estimations of the chlorides in the gastric contents after fractional test meals. In the normal subject the acid of the contents gradually rose to somewhere about 0.2 per cent. at the height of digestion and then gradually fell towards zero as the stomach emptied; if gastric juice of constant strength continued to be secreted throughout the curve must continue to rise steadily; but, if secretion stopped when the acid peak was reached the acid concentration of the gastric contents would remain at that level and the curve would appear as a horizontal line; if the gastric juice fell off in acidity the curve would lie between the two levels, and experiments by Roseman on dogs suggested that such a fall in the acidity of the gastric juice did actually occur, but the lowest percentage reached was 0.319 per cent. HCl, so that it was impossible for gastric juice to act as a diluent of gastric contents which had, on an average, only an acidity of 0.2 per cent. HCl.

The only other process which could bring down the acid of the gastric contents was neutralization. Chloride estimations by the fractional method showed that, as the acid curve fell, the curve of neutral chloride increased *pari passu*, the total chloride curve remaining unaffected. The conclusion was that the true secretory curve was not the acid curve, but followed closely the total chloride curve; and that the acid curve represented the process of neutralization, which in turn depended upon relaxation of the pyloric sphincter. The hypothesis was formed that in pyloric irritability the pylorus refused to relax at the usual time and neutralization failed to occur; the course of the acid curve then depended on the secretory activity of the stomach and the behaviour of the pylorus; it might continue to rise as in the "climbing" curve, or it might draw a horizontal line, or, if the pylorus relaxed occasionally, it might fall with each relaxation and rise again as the pylorus tightened up. There were a number of facts confirming this conclusion.

1. Bile appeared in the stomach from the beginning in the cases of excessive neutralization.
2. In organic obstruction of the pylorus by ulcer where regurgitation was prevented, the acid curve did not fall.
3. Where the pylorus is cut out or after gastro-enterostomy the total chloride curve is unaffected, but achlorhydria is established by free regurgitation.
4. In certain cases of pyloric hypertension atropine in addition to diminishing secretion converted a climbing curve into a normal one by allowing pyloric relaxation.
5. After recovery from dyspepsia the pylorus could be irritated by adding badly cooked split peas to the meal and a normal curve be transformed into a climbing one.
6. The rapid ups and downs that were sometimes seen in the acid curve could only be explained by the vagaries of a sphincter muscle.

Recently objections to the neutralization hypothesis had been brought forward, and it had been suggested that the stomach secreted a juice rich in neutral chlorides, which brought down the acid curve by dilution. MacLean had obtained from dogs, with a Pavlov pouch, acid curves of gastric juice showing a similar shape to those obtained from the digesting stomach in man, during test meal examinations, and he concluded that the same processes were at work in both cases, but the lowest percentage of acid he obtained from a measurable quantity of gastric juice at the end of secretion was 0.2 per cent. HCl, and this would obviously produce no fall in the acidity of gastric contents which was not above 0.2 per cent., however much neutral chloride the juice might contain in addition to the acid. There were a number of observations which were inexplicable on MacLean's hypothesis, one example of which was an investigation on an hour-glass stomach in which no fall of acid was found in the contents of the upper sac, whilst a normal fall was found in the contents of the lower sac; it was impossible to suppose that in this case the upper sac was secreting acid and the lower sac salt. Further information on this point had been obtained by x-ray examinations, and with Salmond he had found that the normal condition was for the duodenal cap to be filled under pressure, not only by the stomach, but by antiperistalsis in the duodenum, which occurred in 93 per cent. of cases examined, and duodenal contents could be seen regurgitating into the stomach. Analysis of his cases strongly supported the view that the hypothesis formed as to the probable course of pathological events giving rise to the pyloric syndrome was correct. Pyloric hypertension as evidenced by deficient neutralization occurred in 76 per cent. of cases with pyloric pain, in 37 per cent. of cases with cardiac pain, and in 25 per cent. of cases with oesophageal pain.

#### *Cardiac Syndrome.*

In contradistinction to the pyloric syndrome symptoms were here manifested in both phases of gastric activity.

*Causes.*—During filling the first cause was bolting the food, which prevented the stomach from accommodating itself in the normal way; the second cause was irritability of the neuro-muscular mechanism, brought about as described in the pyloric syndrome. During emptying abnormal activity of the neuro-muscular mechanism again interfered with normal accommodation, the exciting cause being the irritant nature of the gastric contents.

*Effects.*—With too rapid filling of the normal stomach the contraction tension was raised and a sense of fullness resulted; when irritability had supervened a reflex tonic reaction was at once excited and a sense of fullness or pain was experienced within a few minutes. Although during actual eating pain might be relieved by vagal relaxation of the body, when the meal ended excessive contraction occurred. Such patients felt quite full after eating small amounts, and they reduced their food in consequence; there was thus no stimulus to the lengthening of the muscles, which then contracted all the more. No relief was obtained, therefore, from the diminished diet, and wasting occurred from insufficient food. During emptying increased irritability of the neuro-muscular mechanism produced an increase in the tonic contraction with symptoms which usually appeared between half an hour to two hours after eating. Owing to increased pressure in the body oesophageal regurgitation might occur here as in the pyloric syndrome.

#### *Oesophageal Syndrome.*

Oesophageal symptoms were accounted for by the regurgitation of material or gas from the stomach. This was normally only prevented by the tone of the cardiac sphincter. As long as the gastric contents were neutral regurgitation might occur without producing any sensations. In the later stages of digestion if the gastric contents were acid repeated regurgitation led to increased irritability of the mucous membrane and muscular coat of the oesophagus; ring spasms occurred, accompanied by aching or sensations of tightness, or burning in the lower

chest, and sometimes by severe pain at the ensiform. If the patient was neurotic symptoms were liable to occur whatever the reaction of the gastric contents.

### LEAD TETRA-ETHYL IN MOTOR SPIRIT.

#### COMMITTEE OF INQUIRY.

THE committee which, under the chairmanship of Sir FREDERICK WILLIS, is inquiring into the use of lead tetra-ethyl in motor spirit resumed its sittings on June 6th,\* when Sir WILLIAM POPE, professor of chemistry at Cambridge University, gave evidence.

Sir William Pope was asked about certain ethyl tests which have been carried out in America on a monkey. He replied that in his view such experiments on animals did not afford guidance as to what was likely to happen in man. Other experiments in America, in which a number of garage men concerned in the use of ethyl petrol were compared with certain controls, struck him as having only a slight bearing on the case because the men using the ethyl petrol had, no doubt, been carefully cautioned and were aware that they were exposed to something more than the average risk. The important thing was to ascertain what was likely to happen to the careless garage hand. Asked whether he considered the amount of lead found in the faeces a good index to the lead in the body, he said that it left out of account the effect on the central nervous system. In his view lead poisoning might go on for twenty or thirty years. The fact that in America this substance had already been used for five years without any case of poisoning apparently occurring was not altogether reassuring to his mind; he attached a certain amount of importance to it, but he thought it very probable that public health supervision in the States was not as perfect as in this country. He believed that in the States lead poisoning was not notifiable as it was here, so that it was not, perhaps, so likely that the authorities would necessarily be acquainted with any cases occurring. He also felt foul of the description of the material as "tetra-ethyl lead"; it should be described as "lead tetra-ethyl." In reply to the chairman's question, he said that he believed the committee would find it very difficult in any reasonable time to answer what was set out in its terms of reference. His suggestion would be that stringent regulations should be drawn up, and a leaflet issued calling attention to the possible dangers.

In answer to Sir C. J. Martin the witness said that undoubtedly if the petrol containing lead tetra-ethyl were splashed about a great increase in the number of cases of poisoning would be found. In reply to Dr. W. E. Dixon, he said that he had himself made lead tetra-ethyl on a number of occasions during the last thirty years; neither he nor his assistants had suffered from lead poisoning, but they had taken no risks. Asked what became of the lead tetra-ethyl when it was absorbed in the body, he said that in his précis of evidence he had given an account of four men who died after such absorption. In two of these cases the volatile lead substance—presumably lead tetra-ethyl—was discovered in the brain; in the other two there was no volatile lead in the central nervous system. Possibly it was a question of length of time; it might have been absorbed in some non-volatile compound. In reply to Sir William Willcox, he said that the slow degeneration wrought by lead on the nervous system might take many years. He agreed that not only had the time factor to be taken into account, but also the possible idiosyncrasy; the careless worker had to be borne in mind.

At the close of his evidence Sir William Pope was again questioned by the chairman as to his evident scepticism with regard to the United States evidence. Sir Frederick Willis suggested that the five years' experience of the United States afforded a certain margin of safety whereby this country, following in its wake, might always have ample warning of any ill effects. Sir William Pope said that he was not altogether satisfied that this would divert any danger in this country. His reason for hesitation was the incomplete character of the United States health records as compared with those here.

Other witnesses examined at this sitting were Dr. H. B. Baker, professor of chemistry, Imperial College of Science and Technology, who expressed the view that there was a danger in lead tetra-ethyl in petrol, and suggested that a conclusive experiment might be made on those who suggested that no such danger existed, and Professor G. I. Finch, also of the Imperial College, who said that while a saving of many millions would be effected in the national petrol bill by the use of lead tetra-ethyl, he thought that, in the absence of proper regulations, it would involve very real dangers to the community, though it might be ten or fifteen years before the effects of the poisoning would be observed.

SATURDAY, JUNE 16TH, 1928.

## THE NINETY-SIXTH YEAR.

PREPARATIONS for the Annual Meeting of the British Medical Association at Cardiff are now well advanced; the programme for the eighteen scientific sections, of which the provisional outline appears in our *Supplement* this week, is nearing completion; and with the forthcoming publication of the Supplementary Report of Council the full record of the Association for the 1927-28 session will lie open to inspection.\* That record is presented primarily to the general body of members in whose name and by whose authority the work is carried on from day to day, and to the elected representatives whose function it is to pass judgement on their behalf upon what has already been done and to lay down the lines of future advance. Beyond this, it should be regarded both as a challenge to the indifference or antagonism of non-members, and as a manifesto to the growing section of the public which takes critical and sometimes captious note of the way in which the medical profession seeks to satisfy the increasing claims of the community for expert guidance in all that affects the common health no less than for individual help in sickness and accident. The record must be studied in detail to appreciate its full scope and significance, but something may be gained also from a cursory review that throws into relief the resources at the command of the Association and the manner in which they are being employed.

Membership, a useful if not an exhaustive index to vitality, shows healthy progress. The figure to-day stands at 33,700—an increase of over 1,300 since December, 1926, and over 9,000 in the past five years. The progress of the Medical Association of South Africa as an integral part of the British Medical Association has amply justified the high hopes with which incorporation was accomplished in the opening days of last year; and the presence of Dr. Braekenburg at the South African Medical Congress in Bloemfontein and the general success of his mission have demonstrated not only the strength but the practical value of the bonds established by the Association between the profession at home and overseas. Arrangements for the Annual Meeting of the Association at Winnipeg in 1930 are already in hand, and preliminary consultations have taken place in London between delegates from Canada (Dr. T. C. Routley, General Secretary of the Canadian Medical Association, and Dr. J. D. Adamson of Winnipeg, representing the Manitoba Medical Association) and the officers and officials of the British Medical Association. The report from Ireland lays stress on the impetus to medical organization given by the Medical Secretary's visit early last year. Alike in Scotland, where the Edinburgh office has been enlarged, and at the headquarters in London, where the ground is being rapidly cleared for the first part of the building scheme sanctioned by the Representative Body last year, the Association is providing itself with homes in keeping with its status and activities. Meanwhile, lest growing

numbers and growing material resources should tend to the inertia of institutionalism, the machinery of the Association is under constant scrutiny, and modifications are always being made to keep pace with fresh developments. The inauguration in the past year of special groups of spa practitioners and consulting pathologists has given the Association an opportunity to approach, by way of schemes for the spa treatment of insured persons and for the ordered development of pathological services, problems of real importance to the public and the profession in a manner which appears to justify this new phase of organization.

Its primary object—the promotion of the medical and allied sciences—the Association has served through the customary channels. The circulation of the *British Medical Journal* still exceeds the growing membership, and there is abundant evidence of the care with which its pages are studied by readers in all parts of the world. A larger amount of money, which includes a special grant to a supervisory centre for rheumatic children, has been distributed for the promotion of research, and more and more use is being made by members of the improved service now given by the Association's Library. There is also a steady demand from the Branches and Divisions for British Medical Association Lectures. The special feature of the year's work for the advancement of medical science has been the inception of two schemes for collective research. This is a return to—or rather a development of—an undertaking in which the Association was a recognized pioneer nearly seventy years ago, and for which it commands to-day resources hardly dreamed of by those who set on foot the modest venture of 1862. The response to the recent inquiry into the after-results of gastro-enterostomy has already surpassed the most sanguine hopes; that on the treatment of varicose ulceration shows good progress.

In its special reports on lunacy and mental disorder, on puerperal morbidity and mortality, on treatment by electricity and radiation, and on the possibility of formulating an international medical code for use at sea—just as in the working out of a scheme for the alternative provision of ophthalmic benefit under the National Health Insurance Acts through clinics—the main task before the British Medical Association has been to secure agreement on the best way to safeguard and extend the application of existing knowledge for the benefit of the community. It is in the preparation and discussion of such reports as these that the Association makes its most characteristic contribution to the education of the public in health matters, by securing a consensus of professional opinion upon questions in which the many conflicting voices tend to confuse both the administrator and the general public. That the more direct means of guidance are not neglected is shown by the list of bodies, official and voluntary, on which the Association is represented and with which it has conferred. In the conference on the remuneration of non-professional teachers and research workers, attended by representatives of most of the medical schools in Great Britain and Ireland; in that on puerperal morbidity and mortality, at which every type of expert worker concerned in the problems of midwifery took part; and in the discussion on contributory hospital schemes, attended by some 250 representatives of the medical staffs of hospitals throughout the country, those best qualified to speak on the several matters under review have been brought together by the Association. Progress has been made also with inquiries into psycho-analysis and into encroachments upon the sphere of private practice, although the reports of the special

\* The Annual Report of Council for 1927-28, with Appendixes, was printed in the *Supplement* to the *British Medical Journal* of April 28th. The Supplementary Report will appear on June 30th. These two documents form the basis for the deliberations of the Annual Representative Meeting at Cardiff from July 26th to 28th.

committees dealing with these subjects will not be available for discussion this session.

Turning next to the large and important field of professional life watched over by the Insurance Acts Committee, it should be borne in mind that the revision of disciplinary machinery has still to stand the test of experience, and that the Committee's work arising out of the Insurance Bill whose terms are now before Parliament is by no means completed. Here, as in all that the Association undertakes, it may be claimed that the economic basis of efficiency and the essential conditions of freedom and responsibility in every form of medical practice have been kept constantly in view. One feature only of the year's work calls for an admission of failure. It must be owned that the £4,000 or so collected by the Association for distribution among medical charities during 1927 falls lamentably short of the annual income of £20,000 which the Council desires to secure for this purpose. Let us hope that the increase of more than £1,000 over the amount collected in 1926 may be taken as an earnest of better things to come.

Such in barest outline is the record of the past twelve months. If it compares not unfavourably with that of other less peaceful years we shall do well to recall with gratitude the many devoted workers whose capacity for service and for leadership has brought our Association to its present security and pre-eminence. In doing this we shall think especially of two who have passed from us so recently that their loss is hardly yet realized, who finished their work for their profession during the period under review—J. A. Macdonald, formerly Chairman of the Representative Body and Chairman of Council, and at the time of his death chairman of the Journal Committee; and Dawson Williams, for thirty years Editor of this *Journal*.

### THE INTERPRETATION OF HEART SYMPTOMS.

THE study of Medicine, as defined in the official curriculum, is a very wide and comprehensive enterprise. It includes features which do not, at least to those setting out on the voyage, appear to have a very direct relation to the main purpose of the journey. In the necessary discipline of the preliminary studies, the student, naturally eager for practical affairs, is apt to see mere irritating and gratuitous obstacles. Sooner or later, however, he arrives at what he has throughout felt to be his goal—that is, the study of the patient; and it is with this study that he is to be engaged throughout his professional career. The proposition is easily stated; yet the application of it in life and practice is one of the most arduous and anxious tasks to which human nature is ever addressed itself.

The individual problem is to provide the patient with wise and helpful advice, and this necessarily rests on a diagnostic conclusion—a conclusion which, in turn, must proceed from an analysis and valuation of evidence. Thus, in the last resort, it is on the faculty of rightly weighing evidence that the success of the practitioner in relation to the individual patient actually depends. If it is a commonplace to say that part of this evidence is provided by the description which the patient gives of his own sensations and part by the personal observations of the physician, it is not the less true that the comparative value of these two contributions has been differently estimated at different dates. In primitive days the patient naturally and easily held the field. With the development of physical methods of

examination and of extended methods of objective investigation, personal testimony from the patient suffered some eclipse; and the development of laboratory tests made a further contribution to this result. Facts depending on the direct and first-hand observation of the physician seemed to offer themselves as being in degree, and even in kind, testimony far superior to the statements—often vague and halting—contributed by the patient as an account of his own sensations. Undoubtedly at one time there developed in practice a tendency to minimize, and even to disregard, the patient's story, and to rest a diagnostic and prognostic conclusion mainly or entirely on the results of objective examination; and naturally this attitude of mind particularly expressed itself when symptoms affirmed by the patient found no support in the physical facts of the case. In recent years, however, there has been a decided movement towards a higher appreciation of the subjective evidence provided by the patient. In part this has been due to a recognition of the truth that physical methods of examination have their limits, particularly on the negative side; whilst another factor contributing to the same result is the doctrine that the beginnings of disease—the stage where treatment has its greatest opportunity—are to be detected by the interpretation of symptoms rather than by the changes which can be demonstrated by physical signs. From these and other influences the patient's story may now be regarded as evidence having a claim to a degree of attention that it has not always received.

The general proposition here stated is often conspicuously illustrated in patients who are, or on various grounds believe themselves to be, the subjects of cardiac disease. That the majority of fears of this order are ill founded is a familiar experience with every practitioner, but this does not exclude the possibility that a negative conclusion based solely on physical signs may be equally at fault. It is only by reviewing both symptoms and physical signs that a sure diagnosis and a confident prognosis can be reached. This is one of the lessons lucidly presented in the lecture by Dr. Carey Coombs which we publish on another page of this issue. Such symptoms as palpitation, extrasystoles, and fainting attacks naturally cause the patient much alarm, and often lead to considerable emotional disturbances, which in turn are reflected in stories overcharged with emphasis. Dr. Coombs shows that the clinical value of such stories cannot be abruptly determined by the mere absence or presence, as the case may be, of physical evidences of valvular or other cardiac flaw. In other words, the stethoscope is not a final court of appeal in the clinical interpretation of the patient's sensations; it offers a contribution, and indeed an important contribution, to such a task, but its testimony is something to be added to the common stock, and to be considered in relation to the facts presented by the patient as a statement of his own discomforts and inconveniences.

In his lecture Dr. Coombs has set out in considerable detail the clinical features of various forms of heart attacks, and his observations, we feel sure, will have a wide range of helpfulness. They are evidently based on first-hand and careful bedside observations, and the fact that in some instances the pictures fade away at the margins, that they are not altogether mutually exclusive, and that here and there some individual case escapes classification, only means that they are nature studies, and not, like the academic camel, evolved out of the philosopher's inner consciousness. In this respect they come into the best order of clinical teaching.

There are other features of this lecture that deserve cordial recognition. Granted that the study of the patient is thorough and inclusive, Dr. Coombs is all for the courageous and the confident conclusion. With the "hedging" diagnosis he has neither patience nor sympathy, and he puts "pseudo-angina" into this category; "vasomotor angina," though honoured in the textbooks, he "does not see" in practice; and the welfare of the patient, he urges, has a claim which must take precedence of the practitioner's desire to be on the safe side. If "safety first" is to be the motto, it is safety for the patient rather than for the reputation of the doctor. All this has a decidedly robust note. At the same time it is free from any encouragement to rash and hasty conclusions, for the decision for or against the existence of cardiac danger is to be a considered judgement on all the evidence, and not the outcome either of an easy optimism or of a vacillating mind. "The pain is either cardiac or it is not," and it is the practitioner's duty to "make up his mind about it." These are the stirring terms in which Dr. Coombs exhorts his colleagues to enter the valley of decision.

It may be freely allowed that such an exhortation is not inappropriate to the field of cardiac diagnosis and prognosis. Doubtless nowadays cardiac murmurs, or at least some of them, have had their importance reduced, but even when this is allowed a suggestion of cardiac disease sometimes provokes a "be on the safe side" policy, and under this restrictions are imposed which are without justification unless cardiac disease is actually present. Unnecessarily to deprive a child of the activities appropriate to its age, or to leave an adult suffering from functional palpitation under the depressing verdict of "a weak heart," is certainly not "the safe side" for the persons principally concerned. The medical attendant may sometimes have to take a risk, and he will certainly make some mistakes. But, given the necessary investigations and an informed judgement, the interpretation of symptoms having *prima facie* a cardiac significance ought to be undertaken with confidence and concluded with decision.

### OBSCURE DENTAL SEPSIS.

To the onlooker in medicine few things have been more impressive in recent times than the awakening of medical interest in dental and tonsillar sepsis as factors in obscure systemic infections. That there has been a gradual change of attitude on the part of the family medical attendant towards his patients' teeth will scarcely be denied. How many doctors fifteen years ago thought of toxic absorption from a tooth socket when treating a case of sciatica or of unexplained pyrexia? In the early days of enlightenment pyorrhoea alveolaris was thought to be of prime importance; now it is apical sepsis that holds the centre of the stage, and the pulpless tooth—the "filled dead tooth"—is increasingly recognized as a menace to health. Bit by bit the evidence has been sought for, and pieced together, incriminating hidden dental sepsis as (to say the least) a predisposing cause of general disease. The fruits of the pioneer work of Dr. William Hunter have thus in the course of a few years become a commonplace of medical practice. In this advance radiography has been of inestimable value. It is true that there is still a good deal of controversy about the interpretation of the x-ray appearances round the apices of pulpless teeth, and that all dental surgeons are not yet agreed as to the treatment of such teeth; but with improved

technique and growing attention to the subject knowledge is accumulating.

A further effort towards systematization in the diagnosis of obscure dental sepsis is made by Dr. J. F. Brailsford in the article illustrated with radiograms which appears at page 1013 of our present issue; and the note by his colleague Dr. Leonard Mackey (printed at page 1021) gives three more proofs of the trouble an infected tooth root may cause until its mischievous activities are recognized and ended. These papers, following recent communications bearing upon the same subject by Mr. Arthur Bulleid<sup>1</sup> and Mr. A. P. Bertwistle,<sup>2</sup> and the debate on the pulpless tooth at the Royal Society of Medicine,<sup>3</sup> indicate very plainly the new outlook on dental sepsis in relation to constitutional disease. Fresh light on the problem, leading to something in the nature of standardized procedure, may be expected in the near future if odontologists and radiologists and pathologists continue to work hand in hand; but it is all-important, we think, that physicians and surgeons and general practitioners should regard themselves as essential members of the team. That the ophthalmologist also is concerned in this matter was preached many years ago by Mr. William Lang, who had noted and reflected upon the close connexion between some eye infections and dental sepsis; and at the congress last April of the Ophthalmological Society of the United Kingdom Mr. A. F. McCallan,<sup>4</sup> when discussing the ocular changes observed in association with focal sepsis, reported that one in five of a consecutive series of private patients coming merely for refraction were found on radiographical examination to have apical abscesses. In short, as Dr. Patrick Watson-Williams wrote the other day, at the end of his paper on nasal and oral sepsis in the etiology of gastro-intestinal and pulmonary diseases,<sup>5</sup> "in medicine there is but one field, which ever calls for team work."

### PLAGUE IN AUSTRALIA.

"ONE time with another," said Sir William Petty, "a plague happeneth in London every twenty years." Less fortunate than old London in this one particular, Australia suffered a revival of plague in 1921 after a respite lasting for only half of the period specified by the Caroline sage. Drs. Cumpston and McCallum have made this recrudescence the occasion of collecting the scattered records of plague incidence in the continent, and presenting them as a consecutive account in *The History of Plague in Australia*.<sup>6</sup> In this volume we find perfect pictures of typical epizootics and epidemics of plague, which fortunately occurred in so small a compass as to make a close study possible throughout. Moreover, in some instances the earliest beginnings of an epizootic were observed and traced to the actual ship responsible for introducing the infection. The close association of human plague and rat plague was always demonstrable, but the experience in certain of the outbreaks brings home to us how readily a rat epizootic may be overlooked, no sign of plague being noticed, nor any rumour of an unusual mortality reaching the authorities, until the sudden occurrence of a human case leads to the discovery of numbers of mummified rats, presumably dead of plague, in or near the premises affected. On the other

<sup>6</sup> *The History of Plague in Australia, 1900-1925*. By J. H. L. Cumpston, M.D., D.P.H., and F. McCallum, M.B., B.S., D.P.H., D.T.M. and H. Commonwealth of Australia, Department of Health. Service Publication No. 32. Melbourne: H. J. Green. (Med. 8vo, pp. 238; 12 figures.)

hand, when extensive and systematic trapping, combined with routine laboratory examinations, leads to the early discovery of a rat epizootic, there may be a curious freedom from human plague for a considerable period. The 1921-22 outbreak in Sydney is particularly instructive in this respect; rat plague, of ship origin, was detected in September, 1921, and continued briskly for two and a half months before it spread to man. The secondary foci of infection were established by some means of transport which left the rats of the traversed interval unaffected, and it is interesting that in most of the subsidiary outbreaks infection was definitely centred around some produce store or stable which had been supplied with fodder and the like from the primary focus. The danger to man was everywhere directly proportional to the accessibility of the interior of buildings to rats, having regard to the fact that the disease tended to pick out individual rodents, the majority of the colony being unaffected (an immunity possibly due to the low degree of flea infestation noted below), and that infection was active only in circumscribed areas, which were attacked in succession. On the whole, it appears that *Rattus rattus* (both in its *rattus* and *alexandrinus* subspecies) and *Rattus norvegicus* were of about equal importance as sources of plague, but the proportion of infected mice was at times high. Thus among 1,335 plague-infected rodents captured in Sydney there were 567 *R. rattus* (the common ship rat in Australia), 397 *R. norvegicus*, and 171 *M. musculus*, though in no instance were infected mice found except in association with plague-stricken rats, and there was nothing to suggest that mice of themselves served as an independent focus of disease. As would be assumed, *R. r. rattus* and *R. r. alexandrinus* were found to interbreed readily, but all attempts to cross *R. rattus* and *R. norvegicus* failed, for the doe of each species repelled the advances of the male of the other, and the consequent combat resulted in the rout of the *rattus* male or in the death of the *rattus* female, the fiercer *norvegicus*, whatever the sex, holding the field. The Siphonaptera, exclusive of fleas, taken from rodents were all embraced in the genera *Xenopsylla*, *Leptopsylla*, *Ceratophyllus*, *Ctenocephalus*, and *Pulex*, in the order of frequency, with a general preponderance of the species *X. cheopis*. Rats harboured a surprisingly high percentage of mouse fleas (*L. musculi*), sometimes over 40 per cent. of the total catch secured. The flea population per rat, as recorded, was very scanty; in Sydney, for example, among 20,000 rats there was an average of only one flea to every eight rats, which suggests that some considerable number of rats sent for examination may have been already dead and deserted by their ectoparasites. Within the same period 8,000 mice are recorded as having harboured the astonishing total of twelve fleas. Plague in Australia, both rodent and human, was strictly seasonal in its incidence, and reached its maximum intensity in summer, to die down again in winter—that is to say, keeping pace with the activities of the insect vector, for, as was written centuries ago, "The fleo . . . wexeth slowe and fayleth in colde tyme, and in somer tyme it wexeth quiver [alert] and swyft, and spareth not kynges."

#### INCOME TAX: CHANGES IN PROPRIETORSHIP OF PRACTICE.

During the past two or three years substantial changes have been made in the general scheme of assessment for income tax; it is opportune to refer to one alteration—namely, the fiscal consequences which now attach to a change in the proprietorship of a medical practice, if effected after April 5th, 1928. Prior to the year 1927-28 the "three years' average" formed the basis of assessment, notwithstanding the fact that the result was to charge a successor on the basis of the earnings of another

man, but as a check on the hardship which that rule might have created, the successor was entitled to have the assessment revised to the amount of the earnings for that actual year, provided that he could show that the profits had fallen short from some specific cause since or by reason of the change. For the year 1927-28 the three years' average basis was replaced by that of the previous year, but this proviso remained in force. As regards changes subsequent to April 5th, 1928, the proviso disappears, and is replaced by an entirely different rule. Unlike the former option, that now given to the taxpayer is such that it is unwise to postpone its consideration; the matter has become one to be discussed and settled at an early stage, preferably as part of the negotiations for the purchase or sale of the practice or share which it is proposed to transfer. The change may, of course, be complete, as where a single-handed practice is transferred from one practitioner—or his executors—to another, or partial, where a share only is transferred and there remains in the group of proprietors at least one individual member, who thereby gives partial continuity to the practice. In the business world the former is probably more common than in the medical profession to-day. In the former and simpler case the new rule, Section 32 (2) of the Finance Act, 1926, is definite and conclusive; the practice is to be dealt with as if it had ceased and been recommenced by the successor. Suppose, for example, that A sells his practice to B as from October 5th, 1928. In that case A's liability for the year ending April 5th, 1929, will, so far as that source of income is concerned, be represented by his earnings during the six months ended October 5th, 1928—not by one-half of the assessment for 1928-29, which will have been made on the preceding year's basis—and the revenue authorities will have the option of revising the assessment for 1927-28 to the amount of the profits of that actual year. So far as B is concerned, he will be chargeable for the six months to April 5th, 1929, on the amount of his earnings for that period, and for the year to April 5th, 1930, on the amount of his earnings for the year to October 5th, 1929, with the option of having the assessment reduced to the amount of the earnings for the year to April 5th, 1929, if he wishes. In passing, it may be noted that in cases where the change has adversely affected the profits—not merely the cash receipts—of the practice the new scheme may prove to be a little kinder to the successor and a little more severe to the predecessor than the former method of adjustment. Coming now to a partial change in proprietorship—as, for example, by dissolution or the retirement or admission of a partner, or where a single-handed practitioner takes another man into partnership with him—it is now provided that "the tax payable by the persons who carry on the profession . . . shall, notwithstanding the change, be computed according to the profits or gains of the profession . . . during the period prescribed"—that is, during the year prior to the year of assessment. There is, however, a proviso (and to this matter we wish to direct special attention) to the effect that where all the persons concerned in the proprietorship, whether before or after the change, "require by notice signed by all of them . . . and sent to the inspector of taxes within three months after the change took place," then the practice shall be treated as if it had ceased and been recommenced—that is, as in the case of a complete change of proprietorship. The result of exercising such an option, both as regards successors and predecessors, will be seen from the illustration given above. It is clear that if the statutory grant of that option is to have any real value, the question should be considered as part of the matters discussed when negotiations for the transfer of the partnership share are proceeding. Not only is that the most convenient time, but in view of its effect on both parties to the transaction, if it is then overlooked or postponed

it may be difficult, if not impracticable, to arrive at unanimity and give the necessary notice within the statutory time limit of three months from the date of change. It is, of course, usual to make that change in a manner and at a time calculated to interfere as little as possible with the normal flow of the practice income, but that is not always possible, and it is not difficult to conceive of circumstances in which failure to consider and exercise the option in question would involve the parties to the transaction in the payment of a larger amount of tax than the full application of the law would have required.

#### NARCOTIC PLANTS.

IN the appropriate setting of the old Physic Garden at Chelsea on June 7th, Dr. W. E. Dixon, F.R.S., reader in pharmacology at the University of Cambridge, delivered a Chadwick Lecture on the subject of narcotic plants. It was an interesting discourse on the various specimens (in the green leaf) which were on the table in front of him, and was lighted up by a genial philosophy. One of Dr. Dixon's observations was the curious fact that all over the world the national beverages containing caffeine were dependent upon plants without any characteristic smell or taste. Of all the alkaloids, he said, caffeine was the most widely used by man. It was found in the leaves and beans of the coffee tree, in tea, and also, in small quantities, in cocoa. It might be said that tea, coffee, and cocoa were not narcotics, but that was because they were not taken in large enough quantities. People of all races seemed to crave for something which exerted on the brain a mild narcotic influence. This craving might be understood among highly civilized peoples, accustomed to work or play at high pressure and subject to the strain of modern life. In such circumstances anything might be seized upon which prevented the exercise for the time of the higher faculties of the mind; but why should the primitive people in Northern India smoke Indian hemp, which also produced a narcotic effect on the nervous system? To some extent it was explained, as was the taking of opium, as a social function. The natives sat round in a ring and practised this indulgence, passing into a state of languid ease, obtaining an exalted sense of their own superiority, and losing their relationship to time and space, so that the minute became an hour. Such was the result which followed the use of the essential oils exuding from certain plants. Often these oils were closely allied, though the plants producing them were very different. Who would imagine that attar of roses, eucalyptus, and turpentine had much in common? Yet when any of these was taken by the mouth the person taking it smelt of roses. In the days of imperial Rome the maidens used regularly to take a drop of turpentine so that the fragrance of the queen of flowers might cling about them. Another essential oil of very powerful properties was exuded from the nutmeg, and in the early days of tea drinking in this country the nutmeg grater was an accessory to the teapot, a little of the aromatic kernel being used to give a fillip to the tea. But, of course, the outstanding example of the narcotic plant is tobacco, whose innocent leaf Dr. Dixon exhibited to his audience. Incidentally, he said, it was a fortunate thing that we did smoke tobacco and not eat it or inject it. This led him on to the generalization that in all these matters, so long as we kept away from the chemist, we were tolerably safe. Who ever heard of the juice of the vine doing any serious harm until the chemist came on the scene and practised his distillations? With opium, again, the great mischief was not done until the chemist came along and extracted its chief narcotic principle, morphine, and offered the hypodermic needle. In the same way, when tobacco was used for smoking it was relatively harmless, although Dr. Dixon emphasized the evil effects of inhala-

tion, pointing out how the CO fixed the haemoglobin, and how even the non-smoker who had the misfortune to ride in a full-blast smoking carriage with the windows closed suffered with the guilty and had a certain percentage of his blood put out of action. But of nicotine it must be said that its effects were marvellous in that it seemed at the same time to soothe the irritability of the supersensitive and to stimulate the dull and apathetic. How to correlate those two actions was a task which must be left to others. On the general question of tobacco smoking and of narcotic indulgence Dr. Dixon remarked on the sad paradox that we seemed to get our chief pleasures in life by escaping out of life. But in smoking he thought there were some values not often considered—for example, the ritual of smoking, the lenitive effect of its rhythms, and the half-unconscious occupations it afforded.

#### THE VINEGAR EEL-WORM.

WITH fitting ceremony the Grocers Company has just celebrated the five hundredth anniversary of the granting of its charter by King Henry VI, though its history goes back much further than the fifteenth century. Long before the Wars of the Roses the grossiers, wholesale dealers in drugs and spices, were merchants of high standing in the City, and even earlier they had been preceded by the pepperers. From their ranks were recruited some of the merchant adventurers whose sailors scoured the seven seas—and discovered much thereby—in the search for those condiments so earnestly desired by our forefathers. Nowadays the Grocers Company has forsaken the high roads of commerce and politics for the quiet lanes of education; and it seems fitting that one of its research scholars in sanitary science should just have completed the publication of a trilogy on the vinegar eel-worm, for if the peppers and spices of the East have fallen somewhat from their esteem in these days of cold storage, vinegar must still, above all, be regarded as the condiment of the people. The vinegar eel-worm has been known to naturalists almost since the discovery of the microscope. It was recognized by Petrus Borellus in 1656, and included by Linnaeus in his *Systema Naturae* in 1765, with the specific name of *redivivum*, a name which indicated the prevalent belief that the worms could revive after desiccation. Linnaeus had placed the worm in his comprehensive and appropriate genus, *Chaos*, from the depths of which it has, we hope finally, been extricated (after a long forensic argument by Mr. Peters) as *Turbatrix aceti*.<sup>1</sup> A few millimetres in length, and just visible to the naked eye as an active little hair-like creature in the surface layers of the fluid, it spends its entire life in vinegar; and in that unpromising material not only waxes abundantly, but manages to lay up a reserve of food in the shape of neutral fats and other substances. Whence it came no one knows. It is conjectured that it originally found its way from the slime moulds on trees, where its cousins are still found. Whither it goes is still obscure, but from Mr. Peters's own experiments it does not seem to take kindly to residence in man, although that must surely be a more salubrious spot than a weak solution of acetic acid of doubtful purity. He has traced it through the entire process of the manufacture of vinegar; it is found spasmodically, being absent now and again when the temperature is too high or when the liquid must pass through filters; it reappears in the most unlikely places, probably being transported from one vat to another by the vinegar fly, *Drosophila* sp. (a relation of that useful little insect which supplies our geneticists with much of their information and many of their theories), until it is finally found in the casks from which the vinegar is drawn off in bulk for

<sup>1</sup> B. G. Peters, *Journal of Helminthology*, Vol. V, pp. 133-142. See also pp. 183-202, and Vol. VI, pp. 1-38.

general consumption, sometimes in such enormous concentrations that 2,000 worms can be found in a single cubic centimetre—which represents about 1 per cent. of the volume of the vinegar! The function of this nematode in our human scheme of things appears to be at least doubtful. It is a fascinating object of study for the naturalist, but it eats the "mother of vinegar," and is therefore something of a nuisance to the manufacturer. In the past it has served as an aid to the quack medicine vendors, and Jabez Hogg records that in his day the charlatan's dupo was often invited to view through the microscope "a drop of fluid derived from his natural juices," doctored unbeknown to him with a drop of vinegar containing the eel-worms. Weil, however, in 1881, suggested that it might act as a facultative human parasite when he found all the members of a family suffering from a gastric disturbance simultaneously with a very heavy infection of the household vinegar. The removal of the vinegar coincided with the disappearance of the symptoms. But *post hoc, ergo propter hoc*, and subsequent investigators have failed to confirm this suspicion; indeed, Mr. Peters swallowed some seventy thousand in vinegar—slightly diluted and sweetened—with no ill effect, except to the worms! He concludes that the public need not be unduly alarmed from the health point of view by their presence in draught vinegar—curiously enough the bottled variety seems invariably to be free. The complete eradication of the worms from all stages of the manufacture of vinegar would be difficult and costly, and the end does not seem to justify the means. A few additional precautions in a well-organized factory would probably secure its exclusion from the storage vats.

#### OTO-LARYNGOLOGY.

In our last issue, at page 982, we gave a general account of the summer meeting of the Sections of Laryngology and Otology of the Royal Society of Medicine, held in London on May 31st and the two following days. The outstanding feature of the proceedings was the communication by Dr. Otto Mayer of Vienna on the pathology of otosclerosis; the microscopical preparations and drawings which he displayed excited the admiration of all. Dr. Mayer, as stated in our issue of May 26th (p. 909), has received the first award of the Dalby Memorial Prize, for his work on the pathology of the internal ear, and he was the guest of honour at the banquet held by the two sections on June 1st. Appropriately, the toast of his health was proposed by Sir Charles Ballance, who was mainly instrumental in founding the prize to perpetuate the memory of Sir William Dalby. Sir Charles vividly recalled the personality and sagacity of one who is already little more than a name to many, and in welcoming Dr. Mayer reminded his hearers of the debt they owed to Vienna, and especially to the teaching of Politzer, Urbantschitsch, and Alexander.

#### THE MEDICAL INSURANCE AGENCY.

We published last week a report of the dinner held on May 30th in celebration of the twenty-first anniversary of the foundation of the Medical Insurance Agency. As was well said by Mr. A. D. Besant on that occasion, the keynote of the Agency has always been service. When the Committee of Management held its first meeting in 1907 it resolved that the whole of the surplus funds should be devoted to the benefit of insured members who had fallen on evil days. This policy was subsequently widened, and since 1910 the Committee has distributed to medical charities upwards of £20,400, of which by far the greater part has been by way of direct grants to the Royal Medical Benevolent Fund and its Guild and to the Royal Medical Foundation of Epsom College. During the twenty-one years of its existence the Agency has negotiated life and

endowment assurance policies securing for members of the medical profession capital sums in the neighbourhood of one and a half million pounds, and has arranged many thousands of sickness, accident, fire, household, and motor car insurances on behalf of medical men and women. The last seven years, in particular, have shown remarkable progress. Whereas the premium income, in round numbers, was £30,000 in 1921, it was £80,000 in 1927, and the annual amount of rebates to doctors insuring through the Agency has increased by £2,000, the total sum thus saved to members of the medical profession being nearly £29,000. Such figures speak well for the prudence and foresight with which the affairs of the Agency are managed. We note with special pleasure a resolution passed by the Committee of Management at the meeting which preceded the dinner on May 30th. It was decided to offer to the Council of Epsom College, out of the funds now standing to the credit of the Agency's benevolent account, £500 to establish a scholarship, to be known as the "Dawson Williams Presentation Scholarship," in memory of the late Editor of the *British Medical Journal*, who was one of the founders of the Medical Insurance Agency.

#### MEMORIAL TO SIR DAVID FERRIER.

In view of his pioneer work upon the functions of the brain and of his scientific eminence, many of the friends and colleagues of the late Sir David Ferrier, M.D., LL.D., F.R.S., are of opinion that in some way his memory should be perpetuated. A committee of subscribers is now being set up, and will meet shortly to decide what form this memorial should take. We are asked to say that contributions, however small, from members of the medical profession will be gratefully accepted and acknowledged. They may be sent either direct to "The Ferrier Memorial Fund," Westminster Bank, 1, Cavendish Square, W.1, or to Dr. Aldren Turner, 18, Harley Street, W.1, who is acting as treasurer. The other signatories to the appeal are Sir Charles Ballance, Professor William Bulloch, Sir James Purves-Stewart, and Sir StClair Thomson.

We publish in the *Supplement* this week a full report of the conference called by the British Medical Association on June 6th to discuss the relation of hospital staffs to contributory schemes for hospital benefit. The attendance was very large, including representatives of the medical staffs of some 40 voluntary hospitals in London and about 150 elsewhere in Great Britain and Ireland.

The annual meeting of the British Association for the Advancement of Science will be held in Glasgow from September 5th to the 12th, under the presidency of Sir William Bragg. The Association has visited Glasgow four times previously—namely, in 1840, 1855, 1876, and in 1901. The discussions will be arranged in thirteen sections, and the presidents of those more nearly related to medicine are as follows: chemistry, Professor E. C. C. Baly; anthropology, Sir George Macdonald; physiology, Professor C. Lovatt Evans; psychology, Professor T. H. Pear; and botany, Professor R. H. Yapp. The subject of Sir William Bragg's inaugural address is "Modern developments of the physical sciences and their relation to national problems." Professor E. A. Westermarck will deal with the study of popular sayings in the Frazer Lecture on social anthropology, and Professor F. G. Donnan will speak on the mystery of life. Numerous excursions and receptions are being arranged in connexion with the meeting. Membership tickets and further information may be obtained from the secretary, at the office of the British Association, Burlington House, Piccadilly, W.1.

# NINETY-SIXTH ANNUAL MEETING of the British Medical Association, CARDIFF, 1928.

TOWER OF CARDIFF  
CITY HALL.

**A**FTER an interval of forty-three years the British Medical Association will hold its Annual Meeting in Cardiff this summer under the presidency of Sir Ewen Maclean, M.D., F.R.C.P., Professor of Obstetrics and Gynaecology in the Welsh National School of Medicine, who will deliver his address to the Association on the evening of Tuesday, July 24th. The sectional meetings for scientific and clinical work will be held, as usual, on the three following days, the morning sessions being given up to discussions and the reading of papers, and the afternoons to demonstrations. The Annual Representative Meeting, for the transaction of medico-political business, will begin on the previous Friday, July 20th. The names of the officers of the eighteen Scientific Sections are published in the *Supplement* this week, together with an outline of the provisional programme; further details will be announced from time to time as the arrangements for the work of the Annual Meeting take final shape. On the last day of the meeting (Saturday, July 28th) there will be excursions to places of interest in the neighbourhood. We publish below the fourth of a series of descriptive and historical articles, written for the occasion by Dr. Donald Paterson. The first appeared on December 3rd, 1927, the second on January 28th, 1928, and the third on April 21st.

## THE COUNTRY ROUND CARDIFF.

VISITORS to Cardiff approaching it from the east become aware of features which distinguish its surrounding scenery from the rest of the Principality. Wales is essentially an upland region, with more than a fourth of its area lying over a thousand feet above sea-level, and its main lines of communication run from east to west rather than from north to south—a factor which has largely determined its political history. From the escarpment of the old red sandstone which forms the northern rampart of South Wales as far as the Bristol Channel on the south, the country is unlike the north and central upland in having a lower relief and the possession of great mineral wealth. Within this area the county of Glamorgan presents characteristics of its own, with two types of scenery which sharply contrast. Its northern two-thirds is occupied by the high ground of the coal-field, the southern edge of which forms a more or less bold escarpment—here and there rising over a thousand feet, like the Garth Mountain that towers over the Taff Valley; and dividing the hill country from the lower undulating district of the Vale. The upland of the coal-field, with flat-topped hills and deeply cut valleys, rises gradually northwards to the Brecon Beacons. Viewed from a height like Twm Barlwm, near Newport, it appears a vast expanse of moorland clothed with rough pasture, uncultivated and uninhabited save by a few mountain ponies and sheep, yet it conceals within the folds of its valleys a dense population, often overcrowded, and affords a marked contrast to the bare uninhabited hills.

On the other hand, the Vale, with its lower relief, is a well-cultivated land, thickly strewn with old churches, country seats, white farmhouses, and ruined castles. Of

the last-named it possesses perhaps a larger number than any district in this country, some still imposing in their grandeur, others in an advanced stage of ruin or decayed into mere sites, eloquent witnesses to the fierce struggle that made life anything but pleasant in the March six or seven hundred years ago.

Glamorgan is a well-watered county. Its chief streams, charming in their variety, run more or less parallel in a southerly direction. Some rise in the Beacons, others within the coal-field, and flow rapidly throughout their

whole length to the sea; few are navigable even at high water. They breach the southern rim of the coal-field in a series of gorges, which afford access to the mineral wealth of the valleys and determined the position of the chief ports—Cardiff depending on the gorge of the Taff, Newport on that of the Ebbw.

On the northern rim of the coal-field, at the head of the Vale of Neath, an interesting example of river capture, due to rapid cutting back of the river Neath and the

diversion of several smaller streams, has given us one of the beauty spots of the county. The capture has resulted in the formation of a valley of great charm, with almost inaccessible limestone gorges, lovely waterfalls, swallow-holes, and underground streams, and the great Dinas Rock, within which, legend tells, Arthur still sleeps fully armed among his knights.

Further east the river Ely—after piercing the ridge upon which Llantrissant, one of the most picturesque of Glamorgan hill towns, with its ancient castle, sits astride—flows down a valley of pastoral beauty and winds across the alluvial Leckwith Moors to fall into the estuary of the Taff under the headland of Penarth. The flooding to

LLANTRISSANT, GLAMORGAN.

which it is subject in its lower course has become a serious matter now that the meadows which took its overflow have been built over with crowded dwelling houses. On its left bank, about two miles from Cardiff, St. Fagan's Castle, a seat of the Earl of Plymouth, built in Elizabethan times on the site of an original castle then in ruins, has a quaint vandyked appearance from the sharply pointed gables round two sides of the frontage.

The Taff, a rapid stream throughout its course, emerges from the Brecon Beacons into a valley that had few equals in charm before industrial change transformed it. The river has been the good fairy of the city—a river goddess presiding over its destinies. From its upper reaches it contributes the splendid water supply which has made the city the healthiest of towns; from its valley and those of its tributaries come the minerals which form the life blood of the port; its waters feed the great docks, whilst in its lower course, flowing between thickly wooded banks, with Castle Coch rising sentinel-like from the steep side of the gorge, and lower down the towers of the Cathedral showing above the trees, it affords to the citizens a fair and pleasing prospect.

To the east the Rhymney River, in escaping from the coal-field, makes a winding detour and ends as a tortuous stream flowing across the Cardiff Moors. Its valley, bare and more shallow in its upper part, opens out lower down, and at Caeprhilly, where it becomes a wide-spreading vale, the eye rests upon the massive ruins of the old castle, the great border fortress that represented the high-water mark of mediaeval military architecture, whose "concentric" system of defences made it too strong to attack, and left it a history almost without feature.

The Vale is watered by numerous short streams, which reach the sea through gaps in the cliff. The Thaw, rising to the north, flows past the old walled town of Cowbridge under the remains of Llanblethian Castle, with its fine gateway, and along by the ruined manor house of Beaupré, which still retains its Renaissance porch, to fall into the sea at Aberthaw. Further west the Ogmore leaves the mountains of the coal-field, passes through the pleasant town of Bridgend, and, joined by the Ewenny, forms the eastern limit of the sandhills close to the sea. Ewenny Priory, on the banks of the latter stream—"the best specimen of a fortified ecclesiastical building which Great Britain can show"—with its massive tower, embattled walls, and magnificent gatehouse, has the appearance of a castle rather than that of a religious house. Lower down is the crumbling rectangular keep of Ogmore Castle, picturesquely placed, and containing some of the earliest masonry work in the county.

The coast-line scenery varies with the nature of the strata. To the east of Cardiff the flat shore of the Wentnogg Level is lined by an expanse of mud. Part of the land is below high-water mark, and, protected by an embankment, is drained by reens. Here the may tree flourishes abundantly, and the pleasant meadows make good grazing ground. Nearer Newport, on the bank of the

Ebbw, lies the well-wooded domain of Tredegar House, the park of which is bisected by the main road and overlooked by a hill topped by an ancient encampment.

West of Cardiff, from Penarth Head to the mouth of the Ogmore, the greater part of the coast is bold, with cliffs ranging from 50 to 100 feet, and attaining their greatest height from Penarth to Sully and in the neighbourhood of St. Donats and at Dunraven. Though the regular bedding of the lias

limestone of which it is formed gives it an appearance somewhat monotonous, it is not by any means tame and uninspiring. The restless mining of the strong tides of the Channel produces crumbling and slipping year by year, and the constant change in the barrier has an interest of its own. At Barry and Sully the carboniferous limestone has resisted the action of the sea, and leaves islands at high-water mark. The same rock is seen in the islands of Flat Holm and Steep Holm, situated halfway between Cardiff and the Somerset coast.

Penarth, whose fine headland with the church on its summit makes it a well-known landmark, is a residential

suburb of Cardiff, having well-kept roads and a promenade and pier that attract summer visitors. Barry, further down the coast, in addition to its extensive docks, has developed alongside them, and yet distinct from them, the sandy bay of its island into a highly successful holiday resort. A few miles west Llantwit Major, a picturesque little town with quaint cottages and inns, has an indescribable air of antiquity. It is remarkable for a striking series of buildings and a church of absorbing interest. St. Donats Castle, two miles away,

is famous for its fine situation at the mouth of a well-wooded ravine running up from the Bristol Channel, and admirably chosen for defensive purposes. The extensive grounds, arranged in a series of terraced gardens leading down to the sea, give it a charming appearance as viewed from the Channel.

West of Ogmore the shore is lined by wide-spreading sand dunes or burrows as far as the estuary of the Tawe, except for a distance of three miles, where the rock emerges to carry the flourishing summer resort of Porthcawl. Beyond Sker, the scene of Blackmore's romance, the wilderness of sand attains its greatest depth, and at Kenfig,

TOWN HALL, LLANTWIT MAJOR.

ST. DONATS, GLAMORGAN.

where it overwhelmed the old town, the fragment of the castle protruding from the sand has recently been proved by the spade to be an upper part of a fine rectangular keep.

A little further west, about two miles from the sea, are the ruins of Margam Abbey, a Cistercian foundation of the twelfth century. Rising behind is a range of hills, richly clad with oak trees and intersected by a deep ravine concealing a mountain stream which supplied the fish ponds of the monks. The most interesting architectural remains are to be found in a polygonal chapter house of elegant proportion and unique in character.

The immediate neighbourhood of Cardiff, in fact—quite apart from the accessibility of the beautiful valleys of Wye and Usk and the magnificent coast of Devon—is in itself attractive for its scenery, and is full of geological, architectural, and archaeological interest. The country further afield we propose to deal with in a future article.

## Union of South Africa.

[FROM OUR CORRESPONDENT IN PRETORIA.]

### MEDICAL MATTERS IN PARLIAMENT.

#### Medical, Dental, and Pharmacy Bill.

THE outstanding feature of the present session of Parliament is the success which is crowning the prolonged efforts made by the medical profession in South Africa to secure satisfactory health legislation. The Medical, Dental, and Pharmacy Bill, which has come before Parliament periodically during the past decade, has at last been passed by both Houses. Only formal proceedings now remain before the bill becomes law. On May 10th the Speaker read a message in the House of Assembly transmitting for information a fair copy of the bill to the Senate, printed on vellum, and forwarded to His Excellency the Governor-General for his assent thereto. The Act will consolidate and amend the existing laws relating to medical practitioners, dentists, chemists and druggists, nurses, midwives, and masseners; the keeping and sale of poisons, and the importation, sale, and use of habit-forming drugs. It will not only penalize any unqualified person practising as a doctor, dentist, or chemist and druggist, but also any unregistered person performing any act specially pertaining to one of the corresponding professions. It provides for the gradual prohibition of unqualified midwifery and nursing, beginning with the larger urban areas and extending throughout the Union as adequate trained assistance becomes available for all sections of the population. It also provides for the registration of dental mechanics, health inspectors, health visitors, and other classes of persons, empowering them to use the title "registered," and prohibiting persons not so registered from using that title.

In previous sessions the bill has invariably had to be dropped because of the delay caused by the concerted efforts of persons not on the medical or dental registers of any of the four Provinces to become registrable. Its successful passage through both Houses of Parliament is to be attributed to the persistence of the present Minister of Public Health, the Rev. Dr. Malan. At the end of the last session of Parliament, when 75 of its 96 clauses had been disposed of in the Committee stage, he agreed to its postponement only on condition that it should be proceeded with in the present session at the point where it had been dropped. As the most contentious points had already been settled the passage of the remainder was through comparatively smooth waters, and no great opposition was encountered. On the passing of the bill through the Senate the organizing secretary of the Medical Association of South Africa (B.M.A.), on the instructions of the Federal Council, wrote to the Minister of Public Health, conveying to him the thanks of the Association and congratulating him on the passage of the bill. Dr. Malan's private secretary, in reply, stated that the Minister thanked the Association most heartily for the kind expression of appreciation and goodwill. Dr. Malan desired him to state that he appreciated very highly the patience shown by the medical profession, and especially their hearty co-operation, without which it would have been impossible for him to accomplish his difficult legisla-

tive task. He earnestly hoped that the same co-operation and goodwill would continue in future in regard to the greater problems in connexion with public health with which South Africa was confronted.

#### Public Health Amendment Bill.

The Public Health Amendment Bill, too, has reached the final formal stages. A slight verbal amendment in the Afrikaans copy was made in Senate. This amendment was approved by the Lower House on May 10th, and a fair copy of the bill was transmitted to the Senate during the same day to be certified as correct and returned. The first bill amending the Public Health Act was passed last year; when introduced it included the substance of this year's measure, but when it became apparent that the whole was liable to be dropped only the clauses dealing with matters of special urgency were proceeded with, and these subsequently became the Public Health Act (1919) Amendment Act, 1927. According to it the Mining Commissioner becomes the local authority in any area proclaimed an alluvial diamond digging. It further provides for periodical visits by medical officers to places lacking medical aid where malaria or other disease is prevalent, to be paid for out of public funds. The rapid passage of the present bill was unexpected, as it contains all the contentious matter dropped from last year's bill. Its principal objects are to provide for the exemption of conscientious objectors to vaccination against small-pox; for the regulation and supervision of the practice of midwives, especially unqualified midwives, in the interests of the public health; and for summary procedure in regard to nuisances of an urgent nature. Some ambiguities have been cleared up, and several minor alterations in the Public Health Act, 1919, which experience has shown to be desirable have been made.

#### Vaccination Problems.

The Act of 1919 made vaccination compulsory on all, and arrangements were made for the systematic enforcement of the requirements for all races throughout the Union. But, from the first, strenuous opposition was offered by conscientious objectors, especially in Natal, and during 1921 a number of prosecutions were instituted in various centres and convictions obtained. Opposition, however, stiffened, and in June, 1922, the Government gave instructions that prosecutions of genuine conscientious objectors was to be discontinued. As there were no available means of differentiating the genuine from the non-genuine, this entailed the complete discontinuance of prosecutions, and a serious falling off in the number of vaccinations was the result. The fall has been greatest among Europeans and Eurafrikaners—that is, among the classes which register births. In many native areas vaccination has also fallen off considerably. This has occurred in spite of the provision of full facilities in both urban and rural areas throughout the Union. Had this position been allowed to continue for a few more years large sections of the population of all races would have been unvaccinated, with the consequent serious danger of outbreaks of virulent small-pox. A large increase in vaccinations occurred in 1926 and 1927 as the result of an outbreak of small-pox in Durban, from which town the chief resistance to vaccination had come. In all, 57 cases occurred, of which 16 were fatal. The borough of Durban and the neighbouring local authorities promptly made vaccination compulsory on all non-Europeans. Vaccination centres were provided, and were immediately besieged by a population demanding to be vaccinated. The local branch of the Antivaccination League took up the attitude that it did not object to vaccination *per se*, but only to compulsory vaccination. A considerable number of conscientious objectors and their families were voluntarily vaccinated. The present bill makes provision for the exemption of conscientious objectors to vaccination. The procedure laid down to obtain such exemption entails more trouble and foresight than to allow the child to be vaccinated in the ordinary way. This, the Minister explained, was intentional, as being the only reliable means of testing the genuineness of the objections. No exemptions are, however, allowed in the face of actual or threatened outbreaks of small-pox; nor may inmates of institutions or persons landing at ports who have recently been exposed to small-pox infection be exempted.

### Supervision of Midwives.

Up to the present local authorities had practically no powers to supervise the practice of midwives. Provision for such supervision is now made; it is provided that:

The Minister may, after consultation with the Medical Council, make regulations as to the supervision by the local authority in the interests of the public health of persons (other than registered medical practitioners) practising midwifery within its district, and empowering the local authority to make and keep a list of such persons and to prohibit any person whose name is not on such list from so practising. Such regulations may empower the local authority to refuse to enter on such list, or to remove therefrom, the name of any person whose practising as a midwife the local authority considers would be prejudicial or dangerous to the public health.

Provision is made for appeal to the Minister of Public Health in the case of an uncertificated midwife, and to the Medical Council in the case of a certificated midwife, whose decisions in each case shall be final and binding on the local authority. Regulations of this kind are urgently needed. The unqualified midwife in this country, often dirty and ignorant, levies a heavy toll on the mother and infant life of the Union. Instances were quoted where whole series of puerperal fever cases have occurred in the practice of one such midwife. This clause was the result of a conference between the Union Health Department, the four Provincial Medical Councils, and a number of the principal municipalities.

### Notification of Venereal Disease.

Compulsory notification of cases of venereal disease by medical practitioners caused some dismay when it was first suggested. The principal Act requires every medical officer of health or district surgeon who knows of a case of venereal disease which is not being treated to report such case to the magistrate, whereupon appropriate measures may be taken. The provisions proved practically unworkable. Apart from the occasional cases that medical officers of health and district surgeons came across personally there was no means of informing them. No duty was laid on the ordinary practitioner to inform the medical officer of health, and if one did so he was liable to a legal action. The amendment in the present bill requires every medical practitioner, who knows or who has reason to believe that any person is suffering from venereal disease in a communicable form, and is not under treatment, to report the matter in writing to the medical officer of health of the local authority. The amendment does not therefore represent any big advance in measures for the eradication of venereal disease. It will not secure any general notification of cases, but will enable practitioners coming across cases which are not under treatment to inform the medical officer of health. The machinery already provided in the principal Act for compulsory treatment if necessary can then be brought into force; this Act requires all reports and records relating to venereal disease to be treated as confidential.

### The Food, Drugs, and Disinfectants Bill.

The Food, Drugs, and Disinfectants Bill is designed to consolidate and amend the laws for regulating the labelling and preventing the importation or sale of food or drugs which are unwholesome or adulterated or incorrectly or falsely described, and for regulating the labelling and preventing the importation or sale of disinfectants which are incorrectly or falsely described. It has passed the second reading and has been dealt with by Select Committee. It is now on the order paper awaiting the Committee stage. Though the parliamentary session is expected to end early in June, and there is still much business to be done, it is very likely that this bill will be placed on the statute book during the present year. The Secretary for Public Health has frequently urged in his annual reports the need for new and effective legislation for preventing the adulteration of food and drugs. The existing laws in the Provinces are inadequate and obsolete. The old adulteration laws, as pointed out by the Minister on the second reading, aimed mainly at safeguarding the public health by preventing harmful adulteration. Nowadays, with the exception of preservatives, deleterious adulterants are rarely used. The principal object of the manufacturer or vendor of adulterated articles of food is to make money

by selling spurious or misdescribed articles, or genuine articles adulterated with cheap but harmless ingredients—in other words, by defrauding buyers and consumers. The old laws were not designed to meet these modern conditions. The public is being defrauded to a serious extent and the public health is being prejudiced by the sale and use of deficient, adulterated, or spurious food articles. Strong and repeated representations urging the need for amended legislation have been made to the Government for many years by chambers of commerce and other bodies. A bill to deal with the matter was first prepared by the Secretary for Public Health in 1917, after special investigation and inquiry. Since then the matter has been brought up annually when the Government's programme of legislation was being prepared, but it was not introduced to Parliament until last year. It is greatly to be hoped that the bill will go forward during next session.

## Scotland.

### Vital Statistics.

THE Registrar-General for Scotland has now issued the vital statistics for the quarter ended March 31st, 1928. Births registered numbered 24,246, this being the smallest in any first quarter since 1919; the ratio is equivalent to 19.9 per 1,000. Of these births 22,485, or 92.7 per cent., were legitimate, and 1,761, or 7.3 per cent., were illegitimate. There were registered 7,382 marriages, equivalent to a marriage rate of 6.1 per 1,000. Deaths numbered 19,385; being 2,445 more than last quarter, but 52 less than in the first quarter of last year; the quarterly death rate was 15.9 per 1,000. In the larger boroughs the death rates ranged from 21.1 in Greenock, 18.6 in Glasgow, 17.7 in Falkirk, and 17.5 in Coatbridge to 11.5 in Motherwell and Wishaw, 11.9 in Clydebank, 13.3 in Hamilton, and 14.6 in Ayr. The deaths of children less than 1 year old numbered 2,584, giving an infantile mortality rate of 107 per 1,000 registered births. The rate is 3 less than in the first quarter of last year, and 2 less than the five-yearly average for first quarters. In the larger boroughs the infantile mortality rate ranged from 175 in Greenock, 143 in Coatbridge, 141 in Falkirk, 137 in Glasgow, and 124 in Dundee, to 82 in Hamilton, 86 in Dumfermline and in Motherwell and Wishaw, and 88 in Perth. In Edinburgh the rate was 94, and in Aberdeen 115. There were 558 deaths from measles during the quarter, 191 from diphtheria, and 431 from influenza.

### Welfare of the Blind in Scotland.

The eleventh annual conference of the Scottish National Federation of Societies for the Blind was held in the town hall, Arbroath, on June 8th. Ex-Baillie Dollan (Glasgow) read a paper entitled "A municipal experiment," describing the scheme managed by a joint committee of some twenty-three municipal and county councils in the South-west of Scotland, which had taken over the administration of the workshops of the Glasgow Asylum for the Blind. This involved a capital expenditure of nearly £32,000, and though the workshops were not expected to be self-supporting the deficit last year had been comparatively small. Negotiations had taken place with the Outdoor Mission for the Blind with the object of bringing all blind welfare schemes under unified control by municipal authorities. The number of blind persons employed in these Glasgow works had increased from 278 to 500. Last year no less than £2,800 had been received in bequests to the municipal institution. Dr. J. Parlange Kinloch, medical officer of health for Aberdeen, gave an address on "The prevention of blindness," saying that this was simply a part of a great preventive service whose aim was to obviate a wide variety of injuries and diseases; the prevention of blindness was dependent on the advancement of this service as a whole. He stated that in 1927 there were 6,937 blind persons in Scotland, but year by year the number of blind children was steadily diminishing. A careful analysis of statistics showed that some 50 per cent. of the cases of blindness in Scotland could have been prevented had the right thing been done at the right time. It could be

accepted that the knowledge as to methods of prevention of disease that resulted in blindness was considerably greater than its practical application. The matter therefore resolved itself into an extension of present health services, including the education of the public in the prevention of disease. Out of 18 per cent. of cases of blindness due to injury only 5 per cent. were due to industrial accidents, while 11 per cent. were due to casual accidents to young people. The speaker emphasized the fact that the inexorable economic necessity of working within their financial resources handicapped local authorities, and was the cause of an apparent reluctance to provide an extension of services for blind persons.

#### Pneumonia in Glasgow.

Dr. Charles M. Smith of the Glasgow Corporation Public Health Department has issued a paper on pneumonia statistics in Glasgow, with special reference to children under 5.<sup>1</sup> Since pneumonia was made notifiable in Scotland by regulation in 1919 cases of the disease have been removed in increasing numbers to the Glasgow fever hospitals. On the average about 50 per cent. of the pneumonia in the city has been treated in those institutions. Dr. Smith finds that notification and hospital treatment have had no obvious effect in reducing the death rate from pneumonia in Glasgow. In the hospitals themselves the case mortality has been stationary; it was 21.5 per cent. in 1919-20 and 21.6 per cent. in 1926, with oscillations between. Nor has there been any constant decline in the general mortality from the disease. In 1920 the deaths under 5 were 941, and in 1926 902, with wide excursions in the intervening years. Reference is made to the effect of environmental conditions on the pneumonia and broncho-pneumonia death rate under 5, which varies inversely with the social status of municipal wards. It moves along with the infantile mortality rate, being a high fractional component of the respiratory death rate, which bulks large at different ages. This reference recalls Dr. Halliday's inquiry into measles prevalence in Glasgow, noted in the *Journal* of March 31st (p. 560). A few years ago it was beginning to be said that the environmental hygiene of soil and water was disposed of and done with; studies like this of Dr. Smith suggest that the environmental hygiene of the air still challenges investigation.

## England and Wales.

#### MacAlister Lecture on Medicine in Art.

THE second annual lecture in memory of the late Sir John MacAlister, secretary of the Royal Society of Medicine, was delivered at the London Temperance Hospital, under the auspices of the London Clinical Society, on June 7th by Sir Berkeley Moynihan, Bt., President of the Royal College of Surgeons. It was a popular lecture to which nurses and a number of the lay public were admitted, and was on the subject of "Medicine in art." Substantially it followed the lines of the lecture which Sir Berkeley Moynihan gave last autumn to the St. Pancras Division of the British Medical Association.<sup>2</sup> He began with the gargoyles of Notre Dame and the "Lincoln imp," and showed what interest there was in the curious deformities, no doubt shaped direct from models by the mediaeval sculptor, to those who viewed them with an eye trained in medicine. Incidentally, these figures often carried horns on the head, and there was also a horn on the head of the most majestic sculptured figure in the whole world—the figure of Moses by Michelangelo, so badly placed in the church of San Pietro in Vincoli at Rome that few people realized what a masterpiece it was. The horn on the top of the head of Moses was supposed to be due to a misreading of a passage in the Vulgate. The most famous of all gargoyles was to be seen in the church of Santa Maria Gloriosa at Venice, and was the subject of an exquisite passage by Ruskin, in which he lamented the leering wickedness, the extreme of debasement, which it portrayed. But when Charcot visited this church and saw the gargoyle he said at once that it was exactly the kind

of hystero-epileptic familiar to the Salpêtrière. The hystero-epileptic was considered in the Middle Ages and earlier to be the victim of "possession," and the imago of him was put especially on the roofs and towers of sacred buildings to suggest that evil spirits had been driven out of the church. Another deformity familiar to very ancient artists was evidently achondroplasia; witness the representations of the great god Ptah of Egypt and Bes of Memphis—the large-headed goggle-eyed dwarf, with the short arms, the gross body, and heavy buttocks. Sir Berkeley Moynihan touched on the representation of diseased persons in some of the great pictures by Raphael and others, and of the emotional expressions in the works of Velasquez, and he made the general remark that often some quite inferior artists, whose names were scarcely known at all, were far more correct in their details of subjects suffering from disease or deformity than were the great masters, obviously because the former stuck more closely to their models. He confessed that of all the pictures he had ever seen in Continental galleries the one which fascinated him most, and the one which he most coveted, was "The contemplation of St. Jerome" in the Louvre. The Louvre authorities were said to have refused to allow this picture to be photographed, but a 100-franc note and the promise of another produced the photograph which he exhibited to the audience; it conveyed, however, little or nothing of the power of the original. In showing some photographs of mediaeval statuary, Sir Berkeley Moynihan said that it was the fashion to deride many antiques to-day from the point of view of anatomy, but he believed this view to be entirely mistaken, and he instanced to the contrary the "Dying Gladiator," which brought into play in a masterly manner the accessory muscles of respiration. He concluded with some ancient works of art representing primitive surgical operations, and mentioned that the first representation of a surgical operation in a work of art in Europe—there were earlier examples in Egypt and in Asia—was a fresco at Pompeii.

#### New Institute of Biochemistry at the Middlesex Hospital.

The opening of the new Courtauld Institute of Biochemistry at the Middlesex Hospital took place on June 14th, when Mr. S. A. Courtauld formally handed over his gift, which was accepted by H.R.H. Prince Arthur of Connaught on behalf of the hospital and by Mr. S. G. Asher on behalf of the council of the medical school. Before the ceremony an address was given by Sir Archibald Garrod on "The place of biochemistry in medicine"; this will be published in the *Journal* at an early date. The new institute is situated on a site separated from the hospital by only the width of a street; the lower part of the new structure is devoted to hospital uses and contains the central boiler-house and engineering plant, and, among other sections, a restaurant for students. Five stories, from the first floor upwards, are given to the Institute. The first floor is occupied by a spacious laboratory for students; with the usual auxiliary apartments, while the second contains a clinical routine laboratory, three examining rooms, and the secretary's office; this floor is connected to the Bland-Sutton Institute on the hospital site by a concrete bridge across the street. On the third floor is a large chemical laboratory with combustion and balance rooms and a large-scale preparation room. A library, an optical dark room, a standardization laboratory, and the professor's private room and laboratory are situated on the fourth floor, while on the fifth are the animal houses. It is interesting to note that, unlike most similar existing establishments, the new institute at the Middlesex Hospital consists mainly of large spacious rooms which will be shared by a number of workers. Those responsible for the plan, after reviewing many examples, have concluded that the advantages of this system outweigh the advantages offered by the provision of a large number of small rooms in which each worker may have separate accommodation. It is contended that, under the latter system, not only are the difficulties of construction and ventilation enormously increased, but it is disadvantageous from an academic point of view to segregate individual workers and so deprive them of the stimulus of contact and criticism given by colleagues engaged on other problems.

<sup>2</sup> *Supplement, British Medical Journal*, vol. ii, 1927, p. 143.

### City of London Hospital for Heart and Lungs: Opening of New Surgical and X-ray Block.

A new surgical block and x-ray department at the City of London Hospital for Diseases of the Heart and Lungs (or, to give it its local name, the Victoria Park Hospital) was opened by H.R.H. the Duke of Connaught on June 12th. The chairman of the committee of management, Sir Alexander Butterworth, addressing a distinguished company who had gathered in a marquee in the hospital grounds, said that the policy of the hospital for some time past had not been to add to its total of beds—which had stood at 185 now for several years—but to spend available money in keeping the buildings and equipment up to date. This had sometimes meant additional building, because modern developments in medical treatment and diagnosis necessitated the creation of new departments, for which a home had to be found. This was the case with the new block or wing to be opened that day. It consisted of an operating theatre, with adjoining rooms for the surgeon and laryngologist, and a set of rooms for the x-ray department, which had hitherto been very inadequately housed. The eightieth anniversary of the hospital had been celebrated by an appeal for sufficient money to place the hospital finances on a satisfactory footing. This effort, thanks very largely to the Lord Mayor of London, had met with a fair degree of success, with the result that the building which His Royal Highness was to open was not saddled with any debt. With this new block and with the new pathological laboratory and research institute presented last year by the Prudential Assurance Company, the hospital was in a better position to carry on its important work than it had ever been before. Sir Ernest Birch added a few words with regard to the interest which the Royal Family had always taken in this institution. The Duke of Connaught was only a few months old at the time when the foundation stone was laid by his father, the Prince Consort, in 1851, and the Duke himself had been president of the hospital for the remarkable period of fifty-six years. The Duke of Connaught said that there had been many changes in the hospital during the period of his association; changes reflecting for the most part the general progress in medicine and surgery. It was essential for a hospital to be abreast of the times, however large and rapid the development in the methods of diagnosis and treatment might be. Diseases of the chest caused more deaths and more long-continued ill health than any other category of illness. Nearly half the deaths in this country were due to diseases of the heart and lungs. Three things were required to meet the need—namely, the most skilful medical work, the most highly trained nursing, and the best equipment. The first and second of these had long been assured, but as to the third this hospital, like others, had had to struggle against inadequacy. The increasing use of surgery in chest conditions and the increasing use of x-rays for diagnostic purposes would make the new surgical block and x-ray department of very great value. His Royal Highness then proceeded to open the new premises, which were afterwards inspected by those present. The new block consists of two floors. The actual operation theatre and annexes are situated on the first floor, with the x-ray department below, and both are connected with the hospital corridors by a lift lobby. The x-ray department consists of a spacious room, and the transformer and other apparatus are in a room adjoining, from which leads are taken to the couch or screening stand. The whole of the fittings and equipment are of the most up-to-date character; the cost of the entire block has been £7,500. In a brochure which was handed to each guest a history of the hospital was given, including an account of the stone-laying by the Prince Consort seventy-seven years ago, at which we read "Mr. Paxton"—the designer of the Great Exhibition then standing in Hyde Park—"also exhibited on the platform designs for a 'crystal sanitarium' in which the purity of the atmosphere should be secured by a process of artificial filtration, and an equable and pure temperature both in summer and winter, the outer air being admitted by tunnels to the centre of the building." The idea never seems to have been adopted, the hospital relying on open windows and open-air balconies.

### Status of Tuberculosis Officers in Certain Counties.

At a meeting of the Joint Tuberculosis Council on May 19th Dr. Lissant Cox presented a memorandum on the report of Dr. Pearso of the Ministry of Health on the co-ordination of the public health services in the counties of Essex, Hampshire, Gloucester, and East Sussex. In view of the fact that in these districts whole-time officers were appointed to act as assistant medical officers of health, school medical officers, maternity and child welfare officers, and tuberculosis officers, the council considered that such a plan would need to be carefully safeguarded if it were not to cause a serious deterioration in the tuberculosis service. The assistance in diagnosis or treatment of a consultant tuberculosis officer should be available for every case of definite or suspected tuberculosis. Dr. MacNalty had stated that it was the policy of the Ministry of Health to carry out the recommendations of the Astor report. In rural areas the Ministry were sometimes asked to sanction the appointment of assistant tuberculosis officers who were also responsible for other public health services for reasons of convenience and economy. In such cases the Ministry advised the appointment of a chief clinical tuberculosis officer with special experience, and also required the assistant tuberculosis officers to have had a certain amount of experience in tuberculosis. Professor Lyle Cummins, Sir Henry Gauvain, and Dr. Sutherland were appointed to represent the council at the International Tuberculosis Congress at Rome. It was decided that a dinner should be given to Canadian tuberculosis workers when visiting England in October next.

## Correspondence.

### THE WAR EMERGENCY FUND.

SIR,—The activities of the War Emergency Fund Committee have now come to an end. The first case of distress was relieved in 1915 by the Royal Medical Benevolent Fund, but it was soon found that a special subcommittee—the War Emergency Fund Committee—had to be constituted, and that an appeal for larger funds was necessary.

The War Emergency Fund was instituted to afford assistance to those members of the profession who, in consequence of having joined the Medical Service of the navy or army, found themselves in temporary financial difficulties. The late Sir Alfred Pearce-Gould, who died in 1922, was the first chairman. Amongst those who served on the committee were: Sir William Lister, Mr. T. P. Legg, Dr. Andrew Elliott, Sir D'Arcy Power, Dr. Charles Buttar, Sir William Wilcox, Sir Charters Symonds (honorary treasurer), and Dr. Newton Pitt (honorary secretary).

Applications for assistance were received from 297 medical men; of these, 160 cases were relieved, and the other 137 cases were either ineligible or were assisted in other ways to secure the help they required. From 1920 most of the applications made were for assistance towards educational expenses. Assistance for education has been given to 75 boys and 30 girls, who have attended the following schools: Taunton, Bournemouth, Cranwell, Harlow, Nottingham, Tunbridge Wells, City of Oxford School, Westminster, Durham, Malvern, Wellingborough, Southbourne, Edinburgh, Bromsgrove, Purley, Hunstanton, Woolwich, Epsom, Kelly, St. Paul's, Colet Court, Tonbridge, France, Denstone, Cardinal Vaughan's School, St. Peter's York, Sunderland, Ampleforth, Malton, Wimborno, Blackheath, St. Anne's, Holt, Bedford Training College, Bury, Alderley Edge, Froebel, Littlehampton; University College Hospital, St. Bartholomew's Hospital, St. Mary's Hospital, and Guy's Hospital. The total sum paid in aid of education of the children of these medical men was £18,946 9s. 10d.

Grants have also been made towards insurance, rent, maintenance, debts, and surgery requisites, and help has been given towards the purchase of practices, examination fees, etc. The total sum raised was £32,458 16s. 8d.

The grants given were:

	£	s.	d.		£	s.	d.
1917 ...	290	4	0	1923 ...	3,956	4	5
1918 ...	697	16	2	1924 ...	2,470	17	0
1919 ...	7,552	15	2	1925 ...	1,778	4	2
1920 ...	5,926	17	6	1926 ...	291	4	0
1921 ...	5,622	14	5	1927 ...	85	0	0
1922 ...	6,204	17	9				
					£34,876	14	11

This letter is not written primarily to acquaint the profession with the way in which the War Emergency Fund has been administered, but to tell the story of the wonderful, long-continued, unobtrusive, self-sacrificing labours of two members of the committee who investigated, visited, interviewed, and corresponded with applicants for grants. Their recommendations were almost invariably accepted by the committee, and without their aid and advice the fund could not have functioned without making many mistakes. These facts we think should be known. The whole profession will be proud to learn of the splendid selfless service to their comrades in distress of Sir Charters Symonds and Dr. Newton Pitt.—We are, etc.,

THOMAS BARLOW,  
President of the Royal Medical Benevolent Fund.  
CHARLES BALLANCE,  
Chairman, War Emergency Fund Committee.

London, June 6th.

#### MEDICAL REGISTRATION IN NEW ZEALAND.

SIR,—The attention of the New Zealand Medical Council, the registering body in this Dominion, has been drawn to a letter by "Traveller" appearing in your issue of January 14th (p. 77). Many statements contained in this letter are incorrect. The whole communication is written from the point of view of one particular case, which possessed unusual features, and the inference that the experience of this individual is representative of all is untrue.

It will be well to state the normal procedure. Section 9 of the Medical Practitioners Act, 1914, states:

"(1) Every person desiring to be registered under this Act shall cause at least one month's notice of his intention to apply for registration to be published in the *Gazette*, and also in some newspaper circulating in the district in which the applicant intends to practise; and shall, at least one month before the date of his application for registration, deposit in the office of the Registrar nearest to the place where he intends to practise his diploma or other original evidence of his qualification, or a true copy of any such document certified as correct in the prescribed manner."

Section 10 of the same Act explains why a medical man seeking registration must advertise as stated above:

"(1) Any person who has reason to believe that an applicant is not entitled to be registered or is not a fit person to be registered under this Act may, at any time before that applicant is so registered, object in writing to his registration, and shall specify the grounds of his objection."

An applicant, having lodged an application, deposited his diplomas for inspection, and advertised as required by the law, is asked to fill in a confidential form of inquiry, on which the following particulars are requested:

1. State consecutively where you have been practising since qualifying.
2. In what other country or countries are you registered as a medical practitioner?
3. Has your name at any time been removed from any medical register in any country where you have been registered? And, if so, on what date and for what reason?
4. Give names of two or three persons (both in New Zealand and elsewhere) to whom you could refer the Council for information as to your character (if necessary).
5. What were your reasons for coming to New Zealand?

This information is obtained to enable the Medical Council to satisfy itself, in terms of Section 8 (2) of the Act, that the applicant is satisfactory from the point of view of good fame and character. Past experience has proved the necessity for this procedure.

As soon as the application is received it is the usual practice, if the documents are in order, and without waiting to make any inquiries whatever, to issue to the applying doctor a provisional certificate of registration, which enables the applicant to engage in medical practice immediately if he so desires. This provisional certificate holds good for three months, and is automatically renewed (without application) at the end of that time, if necessary. The fee for medical registration in New Zealand is £5, being the same as the fee at present payable in Great

Britain. . . . . New Zealand Medical Gazette costs 5s., . . . . . 7s. 6d. per inch.

In the case referred to by "Traveller" the medical degrees possessed by the applicant were not obtained in Great Britain, and are not now registrable in New Zealand. The applicant ignored repeated communications from the Medical Council, and persisted in practising without any form of registration whatever. It was in these circumstances that the police authorities prosecuted him for practising without registration.

If medical men possessing qualifications obtained overseas intend settling in New Zealand they would be well advised to ascertain beforehand whether their degrees are registrable in this Dominion. If so, and if they bring with them satisfactory recent references as to character, they need have no fear as to obtaining registration in New Zealand.—I am, etc.,

C. J. DRAKE,  
Secretary to the Medical Council of  
New Zealand.

Wellington, May 1st.

#### THE ORIGIN OF ISCHAEMIC CONTRACTURE.

SIR,—Mr. Trethowan (June 9th, p. 1001) writes that Professor Hey Groves in his article (May 12th, p. 807) makes no very helpful deductions to guide us in the anticipation and prevention of the "nightmare" of ischaemic contracture. Actually, Professor Hey Groves says, "It should be clearly understood that it is always a most dangerous thing to flex a swollen elbow-joint." The helpful deduction is obvious—don't. Every fracture about the elbow-joint is accompanied by swelling.

For years it has been taught on high authority that fractures about the elbow-joint (excepting fracture of the olecranon) should be treated in acute flexion or full flexion, and all will be well. This teaching is widely followed; indeed, acute flexion has become almost a ritual in practice, and surprise is expressed again and again when it turns out that all is not well.

It should be widely taught that to put up a recent fracture of the elbow in a position of acute flexion is a most dangerous procedure, especially as "acute flexion" is so often taken to mean the impossible position of the hand on the shoulder of the same side. I do not for a moment mean to suggest that a reasonable amount of flexion cannot be employed in many cases with impunity; but the ritual of acute flexion and some of the fallacies associated with it need to be suppressed.

Speaking particularly of supracondylar fracture of the lower end of the humerus, it is commonly thought that acute flexion of the elbow-joint prevents the formation of callus and of a bony block in front of the joint. Both the callus and the bony block are due, not to the position of the elbow-joint, but to faulty reduction of the fracture. Acute flexion is quite commonly thought to be a means of reducing the displacement of the lower fragment. This is mechanically unsound. We see many cases in which the fragment has been simply tilted forwards and its upper end made to project backwards by the blind procedure of acute flexion. It is thought that acute flexion is necessary in order to maintain the position of the fragments after reduction. This again is wrong. Lastly, acute flexion does not correct or control the rotation deformity which is so common in these fractures.

Reduction of an elbow fracture should be effected by direct manipulation of the lower fragment under an anaesthetic, with the elbow-joint preferably extended or moderately flexed. If this fails, the displacement should be reduced by open operation. After complete reduction it matters little in what position the elbow-joint is placed; it may be extended or flexed to a right angle or more, as may seem best. But to force an elbow into flexion in the hope that an incomplete reduction may be rendered more complete, or in the hope that the after-effects of incomplete reduction will be thereby minimized, is asking for trouble.

What is really the best position in which to put up this fracture after reduction? It is admitted that, if there is little swelling, the elbow may be flexed to above a right angle with impunity, and this also has the advantage that the reduction can usually be maintained in this position without the use of splints. But, apart from the

nightmare of ischaemic contracture in case the degree of flexion has been misjudged, there are other, if less serious, disadvantages of the flexed position.

I have already pointed out that flexion does not control rotation of the lower fragment. Orthopaedic surgeons know very well that gradual extension of the elbow from the flexed position does not always follow smoothly according to plan, and some residual contracture of the joint is very common. Lastly, myositis ossificans in this region is aggravated, if not caused, by injudicious attempts to extend the elbow after it has been kept in the flexed position.

On the other hand, given complete reduction of the fracture, very good results can be obtained from treatment with the elbow flexed to a right angle or even fully extended. The latter necessitates confinement to bed, but it should be employed when there is great swelling. Both require some sort of splint, of which by far the best is plaster-of-Paris, which, however, does not mean prolonged fixation in one position.

I would ask whether the disadvantages of "acute flexion" have been fairly weighed against its alleged advantages? It is "universally approved" because it is so easy—at first. Ischaemic contracture is a mass of coagulation necrosis of the muscle fibres, and when once it has occurred there is no going back on it. Was Mr. Kennon greatly daring or did he "rush in" when, as he tells us (p. 1001), he put a cold and pulseless limb into acute flexion?—I am, etc.,

London, W.1, June 11th.

A. S. BLENDELL BARKART.

Sir,—Making some useful comments on traumatic ischaemia in your issue of June 9th (p. 1001), Mr. Trethowan emphasizes the value of pain as a warning symptom. May I supplement his statement by remarking that the pain of ischaemia is characteristic and unlike other pains. Although the sufferer may be unable to describe his discomfort except under some such vague phrase as "a horrible drawing sensation," yet he is likely to understand at once and to answer in the affirmative when asked if it is at all like "pins and needles."

Another point is worth noting. Ischaemic contracture is due to blockage of blood vessels; and soon after its main artery has become obstructed the surface temperature of the limb distal to the obstruction is usually raised, even in the presence of impending or established ischaemia of muscles. The anatomical and physiological reasons for this phenomenon are apparent; but the dangerous fallacy of regarding a warm limb as one with a proved sufficiency of circulation is not yet extinct. A cold limb threatens gangrene rather than ischaemia.—I am, etc.,

London, N.E., June 11th.

HAROLD BUTROWS.

#### THE TREATMENT OF MALIGNANT DISEASE BY COLLOIDAL LEAD.

Sir,—Professor Blair Bell's standing in the sphere of cancer research is well known and requires no comment.

In my report on the treatment of malignant disease by colloidal lead I describe the methods of preparation of that substance and affirm that they are the same as those used in Liverpool. No mere *ex cathedra* statement to the contrary by Professor Blair Bell is of any value; the onus is on him to show wherein the difference lies. It is well known that commercial preparations of lead contain a small percentage of arsenic, and it was for that reason that in my experiments I used a specially prepared lead "shot," which was free from arsenic. Moreover, the criticism carries little, if any, weight, for only 14 patients received one dose each of the lead prepared by myself (of whom the case which improved was one), and no patient received more than one dose; all other doses were obtained from the source which was, and I believe is, supplying Professor Blair Bell himself.

In reply to Professor Dilling's letter, I cannot see how my reasons for using lead hydroxide affect the matter at issue. I used the hydroxide before Professor Blair Bell had published sufficient details of his method of preparing lead to enable others to repeat the experiment. I was aware of Professor Dilling's warning, but while I attach great weight to anything which he may say in relation to pharmacology, I cannot admit that he is

an authority from whom there is no appeal. I therefore decided to test the matter for myself when I was offered the material by an expert in the preparation of colloidal substances. In any case, I am surprised that Professor Dilling should complain of my action; rather he should be pleased, since by doing so I fully confirm his results.—I am, etc.,

London, S.W., June 8th.

STANLEY WYARD.

Sir,—If one compares the investigation undertaken by the Research Committee of the General Hospital, Birmingham, into the treatment of malignant disease with lead, and the investigation by Dr. Stanley Wyard reported in the *British Medical Journal* of May 19th, one cannot help thinking that if all investigations in the treatment of disease were carried out in the spirit of that performed in Birmingham the advance in our knowledge would be greater and our waste of time would be lessened.

It is obvious that it is useless to try any form of treatment, apart from miracles, on people who are dying of cancer, and I do not think that even the most enthusiastic exponent of lead will claim miraculous benefits for this method of treatment.

Included in the list given by Dr. Wyard are 21 patients who did not receive more than 0.2 gram of lead, and of these 14 died, 6 were in *statu quo*, and one, who had only had 0.075 gram of lead, was said to be worse. In 5 of those who died the time they were under treatment is not mentioned; in 7 it was as follows: 15, 45, 21, 35, 35, 20, 36 days. Three of these patients, it will be noted, did not survive more than three weeks. Of the three who survived six weeks one lived 107 days, one 176, and the third, who was labelled as "worse," lived 166 days.

From the results of this administration—I cannot call it investigation—Dr. Wyard expresses an adverse opinion on the method of treatment by lead. It would be fairer, surely, if he had expressed an adverse opinion on his method of treatment by lead. Can any fair-minded or logical man say that anyone is justified in drawing conclusions from material such as this? I cannot think that even the most ardent opponents of the method of Professor Blair Bell would care to quote such evidence.

It is clear from both the Birmingham and the Cancer Hospital reports that the great drawback in the lead treatment is the toxicity of the preparations used. We shall make little progress in the treatment of cancer if treatment can be carried out only in a limited number of places. A widespread disease such as cancer must be attacked by a large number of individuals, and a safe drug is essential to enable them to do this.

My cases of malignant disease are given a course of lead as a routine practice, and no harm has come from this in the past two and a half years. I use Mr. Patterson's colloidal lead iodide (British Drug Houses, Ltd.). I have never had any serious lead poisoning occur with this drug. Many injections have been given in the outpatient department without any ill effects.—I am, etc.,

London, W.1, June 11th.

DUNCAN C. L. FITZ WILLIAMS.

Sir,—In his letter on this subject in your issue of June 9th (p. 999), Professor W. J. Dilling states that, "colloidal lead selenide is safe, but appears to be devoid of inhibitory effect in malignant disease."

I have been engaged in research on lead colloids, especially the selenide, since the autumn of 1925, and have been using the selenide on advanced cancer since 1926. I am not in agreement with the second of Professor Dilling's conclusions. About sixty cases of cancer in man and many hundreds of animals implanted with cancer have been treated. It is found that lead selenide is safe, and that it has a decided action in causing inhibition and some power of bringing about regression of malignant growths. In addition, it has a definite, and often marked, action in diminishing the pain of advanced cancer.

The preparation we use is safe. If the suggested technique is followed it would be difficult to injure the patient. It is not claimed that it is a cure, but that it is a useful and hopeful remedy. Further work is in progress, and it is hoped that improvement will continue.

The preparation we are using has been presented to the

British Drug Houses, Ltd., who will manufacture and sell it. A brochure giving details of technique and all clinical and experimental results up to April, 1928, has been published by Messrs. Arrowsmith, Ltd. Copies may be obtained from the Secretary, Bristol Royal Infirmary, or from the publishers. The concluding paragraph of the preface reads:

"The committee wish it to be clearly understood that no profit of any description from the sale of this preparation or of this publication will accrue, directly or indirectly, to the Bristol Royal Infirmary or anyone connected with it or this research in any degree."

With regard to future criticism of this work it should be clearly understood that the results claimed and the technique suggested are those for the preparation manufactured by the British Drug Houses, Ltd. We intend to use their preparation, and may alter the composition if, on adequate proof, alterations are considered beneficial. —I am, etc.,

Pathological Research Department,  
Bristol University, June 10th.

A. T. TODD.

### HAEMATURIA DURING INSULIN ADMINISTRATION.

SIR,—In their article at page 977 of last week's *Journal*, entitled "Two cases of haematuria caused by insulin treatment," Drs. Lawrence and Hollins suggest that the insulin was responsible for the condition. The haematuria was of very short duration (twenty-four hours or less), and ceased spontaneously in spite of the continued administration of insulin. If the latter had been responsible it does not seem likely that the haematuria would have ceased so promptly. In the first case described the patient had had a severe tonsillitis and pharyngitis four days before the onset of the haematuria and two days before the insulin was started. It is well recognized that a transient haematuria may occur during the course of an acute tonsillitis, and it is possible that the condition might be observed more frequently if the urine of such patients was examined with the care and frequency which is essential in the treatment of patients with severe diabetes. No septic focus was discovered in the second patient, but he was very ill and emaciated, and an infection is often present in such cases, although it may be very difficult to discover, even when pyrexia and tachycardia are present.

The other cases reported elsewhere in the last few years are also unconvincing, especially the one in which tuberculosis of the lungs and arterio-sclerosis of the kidney were present. Drs. Lawrence and Hollins themselves discount the haemorrhages which have been described as occurring in other parts of the body as being merely incidental, and we feel that this view is equally true of their two cases. —We are, etc.,

London, W.1, June 11th.

GEOFFREY EVANS.  
GEORGE GRAHAM.

### ACUTE APLASTIC ANAEMIA.

SIR,—In a review of A. Hayes Smith's book on *Acute Aplastic Anaemia* in your issue of June 2nd there appears the statement "but not everyone will be ready to accept a diagnosis of aplastic anaemia on the absence on two occasions of platelets and polymorphonuclear leucocytes, when the haemoglobin value was only once as low as 58 per cent. and the patient was not sufficiently inconvenienced to be kept in bed." This definitely implies that such was the basis of diagnosis in the case concerned, and as it misrepresents the facts and is incorrect in detail we should like to be allowed to make the following corrections.

The diagnosis was based on the absence of morphological abnormalities in the red cells in spite of the presence of anaemia, the approximately equal reduction in the haemoglobin and red cells, the reductions affecting the elements produced in the bone marrow, but not the lymphocytes; that the anaemia was not merely due to haemorrhage as shown by the fact that the marrow-produced elements, except the platelets, continued to decline after the haemorrhage ceased, this being supported by the normal lymphocyte count, which also helped to show that it was not due to excessive blood destruction, the negative van den Bergh test later providing evidence pointing in the same

direction. The logical interpretation of the facts appears to be an absence or a marked diminution of marrow function.

With regard to the reviewer's allusion to the haemoglobin value, the diagnosis of disease surely does not necessarily depend on its severity at the time of examination, and the fact that acute aplastic anaemia is not usually diagnosed till its later stages is no reason why it should not be diagnosed at any of the intermediate stages through which it must pass from the normal. With regard to the patient not being sufficiently inconvenienced to be kept in bed, the same observation was made in Bruce's fatal case quoted on page 36, the parents not considering the child sufficiently ill for medical attention.

We should welcome any reasoned criticism of the diagnosis which takes into account all the facts recorded. So far we have not encountered one.—We are, etc.,

A. HAYES SMITH,  
C. J. YOUNG.

Bradford, June 4th.

\*\* Our reviewer writes: The observations to which Drs. Hayes Smith and Young draw attention in their letter may, as they say, be interpreted as evidence of a diminution of marrow activity; but similar observations are quite frequently to be made in secondary anaemia of various types, and they cannot therefore form the basis of a diagnosis of acute aplastic anaemia. The evidence definitely suggestive of acute aplasia seems to have been adequately given in the passage complained of. Acute aplastic anaemia as generally recognized is a grave anaemia with severe depression of erythropoiesis as a chief characteristic, and it was therefore not merely legitimate but essential to point out that in this case the haemoglobin content of the blood never fell to a severely low level. As a clinical diagnosis it is perfectly reasonable to suggest that the case was in fact one of acute aplastic anaemia cut short by treatment; but the question whether the diagnosis was sufficiently well established to found upon it a novel hypothesis on the control of marrow activity by a liver hormone is quite another matter, on which readers must be allowed to form their own opinion. Drs. Hayes Smith and Young say that the quotation they give is "incorrect in detail," but they make no attempt to substantiate their charge, and reference to their monograph confirms the details in the review.

### TONSIL-SUCTION FOR DIAGNOSIS AND TREATMENT.

SIR,—Dr. Frank C. Eve raises several points of interest in his article on tonsil-suction for diagnosis and treatment (p. 941). The method is not, of course, a new one. Waring's tonsil-suction tubes, which are popular in the United States and are used in this country, have been on the market for four or five years. I also use a long glass tonsil-suction tube which I have had in my possession for at least ten or a dozen years, and the origin of which I forget, although I think it is American. It is some years since I heard a colleague relate how he had been consulted by an American lady who demanded to have her tonsils "spring-cleaned" by suction; she was accustomed to have this performed each year in her own home town.

Dr. Eve asks for better formulae than those which he has been using up to the present. I would suggest that he would find an excellent formula in the well-known tonsil paint prescribed by Sir James Dundas-Grant: iodine 5 grains, acetic ether (acid-free) 2 drachms, glycerin to 1 ounce. The acetic ether, as Sir James has pointed out, carries the iodine into the depths of the tonsillar crypts. This formula has been used for years with good results by many laryngologists. Another useful application after suction is the "London paste" of Morell Mackenzie, popularized in recent years by Dr. Irwin Moore. This escharotic paste effectively diminishes the size of the tonsil as well as cleansing it; a 10 per cent. solution of cocaine must be painted on the tonsil before applying it.

I do not think, however, that anyone with fairly wide experience of septic tonsils in adults and their sequelae, would agree with Dr. Eve that his method of treatment or suction followed by any application can really be looked upon as a substitute for tonsillectomy. A patient

must come back for treatment year after year, and, between treatment, his tonsils are still unhealthy, although they have been cleaned up and his symptoms improved for the time being. In company with others I use this method—or rather, a similar method—as a temporary expedient only, and in the few cases in which tonsillectomy is refused or contraindicated. Squeezing with a spatula, I can assure Dr. Eve, is in reality by no means “agonizing”: I have experienced it myself as well as applying it to others every day. But when I can suck or squeeze foul pus—and not merely one or two little concretions—from a tonsil, and I find that the patient has signs and symptoms of ill health that can fairly be attributed only to the presence of septic tonsils, I am still convinced that it is my duty to advise tonsillectomy, in spite of the temporary improvement that I know can often follow tonsil-suction and painting.—I am, etc.,

London, W.1, June 2nd.

R. SCOTT STEVENSON.

#### NASAL AND ORAL FOCAL SEPSIS IN DISEASE.

SIR,—In their article published on June 2nd (p. 931) Drs. P. Watson-Williams and F. A. Pickworth draw several conclusions with which I most heartily concur. I can support the theories advanced with an interesting fact from a different point of view. In a series of several hundred cases I have never seen or removed an acute appendix in a patient whose tonsils had been cleanly enucleated in childhood. This, of course, may be merely coincidence, but various surgical colleagues have been unable to quote contradictory cases. It is also a fact that patients with chronic tonsillitis often have a tender spot in the right iliac fossa, and probably most of us have seen at least one case of fulminating appendicitis a week or two after tonsillectomy.

There seems to be no doubt that with the increasing incidence of appendicitis from the beginning of the present century, follicular infection of the tonsils is becoming far more common than before, particularly among the present generation. This leads to the inevitable conclusion that, whatever dietetic deficiency may be at the root of these evils, we have one remedy at hand to check our emergency operations for acute appendicitis. I would go further than this, and say that many cases of gastro-duodenal ulcer, gall-stones, and chronic pancreatitis would be prevented if septic tonsils were habitually removed in childhood before a latent infection of other lymphoid tissue elsewhere in the body had been permitted to occur.—I am, etc.,

JAMES S. HALL, M.B., B.S. Lond.,  
F.R.C.S. Ed.

Walmer, June 4th.

#### ABORTION AND SEPSIS.

SIR,—Amid the considerable number of articles on puerperal sepsis recently produced it is remarkable that such little notice is taken of the effects of abortions and miscarriages on the mortality of this disease. This may be partly due to a misconception of the mortality rates of puerperal sepsis as published in the Registrar-General's reports. These are recorded as per live births, and the deduction appears to prevail that this refers to deaths occurring amongst live births. As a matter of fact, the rate is based on live births, and includes post-abortion deaths as well as post-partum deaths.

That this is the correct interpretation is evidenced by the statements in the Ministry of Health publications No. 25 (p. 34) and No. 48 (p. 13). Owing to the inclusion of these two undifferentiated causes it is impossible to draw conclusions from comparisons of the sepsis rate in institutions or midwifery services which are based on delivery data only, and the sepsis rate amongst the general population outside these organizations, which includes deaths from abortions and miscarriages.

The influence of abortion merits a great deal more attention than it at present receives. Germany appears to be the only country publishing separate records of deaths from sepsis following abortion. In that country half the puerperal sepsis mortality in towns of over 30,000 inhabitants is post abortum (Ministry of Health publication No. 48, p. 13). In an analysis of the maternal deaths in

a large industrial town in England out of 51 deaths from puerperal sepsis in three years no fewer than 25 were post abortum (Ministry of Health publication No. 25, p. 34). The puerperal sepsis death rate of 1.6 per 1,000 live births for England and Wales in 1926 would therefore be considerably reduced if the post-abortion cases were deducted.

It is worthy of note that in the report of Dr. Remington Hobbs's lecture in the *Journal* of June 8th (p. 971) a table is given showing the admittance of 192 cases of abortion and miscarriage during two years in one London institution alone. From the above figures the total number of abortions and miscarriages in this country annually must reach enormous proportions. It may well be that research into the problem of abortions would throw considerable light on the maintenance of the puerperal sepsis mortality rate at its present level in many localities in this country.—I am, etc.,

London, S.W.16, June 8th.

E. HUPSON.

#### ETIOLOGY OF CANCER.

##### A Request to General Practitioners.

SIR,—May I ask those of your readers who are engaged in general practice and who would be willing to answer a series of questions relating to cancer cases to send their names to this laboratory? All that is necessary at the moment is to put a visiting card into an envelope or write name and address on a post-card, and forward it to me at the Department of Applied Statistics, University College, London, W.C.1.

The object of the inquiry will be to try to throw some light on the vexed question of cancer etiology, and this will necessitate information relating to a large number of cases from all parts of the country which cannot be obtained in any other way. The identity of the cases need not be revealed, and the forms will be so devised that scarcely any writing is required.

Such appeals have sometimes met with a disappointing response in the past, and it is therefore not proposed to proceed with the investigation unless a sufficient number of helpers is first assured.—I am, etc.,

PERCY STOCKS,

Reader in Medical Statistics, Galton  
Laboratory, University College.

#### THE MEINICKE SYPHILITIC REACTION.

SIR,—Professor D. T. Barry's letter in your issue of May 5th (p. 775) is evidence of the slight attention that the Meinicke turbidity test has received from English pathologists. There are so many points in favour of Dr. Meinicke's procedure, however, that it is replacing the Wassermann test in certain laboratories in Central America. The reagents entering into this test are confined to (1) the antigen diluted with 3 per cent. saline solution, and (2) the serum to be tested. No complicated apparatus is required, and anyone having the slightest knowledge of laboratory methods is able to perform the test. The results are either positive or negative, the “doubtful” result of the Wassermann test being largely eliminated.

Dr. L. M. Moody and I have been engaged in comparing results obtained by the Wassermann test (method of McIntosh and Fildes) with those obtained by the Meinicke test (modification by Eichelbaum). We have not yet investigated the cases in detail, but one outstanding difference is patent: antisyphilitic treatment will sooner convert Wassermann-positive serums to Wassermann-negative than it will convert Meinicke-positive serums to Meinicke-negative. The patients have not been under observation long enough for us to ascertain the significance of this with regard to relapses. The antigen used has been obtained from Westfalen and appears to keep indefinitely.

Professor Barry states: “The reaction is considered to be of great value . . . and practitioners are advised to get it adopted in laboratories to which they look for diagnosis . . .” The procedure, however, is so simple that even a busy practitioner can add this test to the armamentarium of his clinical laboratory without appreciably increasing the demands on his time.—I am, etc.,

Kingston, Jamaica, May 24th.

GEO. P. F. ALLEN.

The Society of Apothecaries of London announces its intention to institute a Mastery of Midwifery and to issue a diploma under this title denoting the possession of specialized knowledge of ante-natal care, midwifery, and child welfare. References to the proposal were made on several occasions last year, notably on August 6th (p. 225), and the regulations are now available. It is intended to hold the first examination in the autumn and to make this a severe test, so as to ensure a high standard of professional knowledge. The diploma will, however, not be registrable under the Medical Acts. In initiating this qualification the Society has been moved by consideration of the need for organization and improvement in the practice of midwifery and cognate matters, and by a sense of its own traditions in promoting the advancement of medical knowledge among general practitioners. Admission to the new diploma is not confined to licentiates of the Society, but is open to all who have been for not less than a year in possession of a registrable medical qualification. The regulations prescribe that, after qualifying, candidates must have held, for at least six months, a resident appointment in a recognized institution concerned with obstetrics, and must have attended, for periods of three months in each case, a recognized ante-natal clinic and a recognized infant welfare centre before entering the examination. Until 1932, however, special conditions will apply to practitioners of ten years' standing. The examination will be conducted by written papers and by clinical and oral tests. Copies of the regulations may be obtained from the secretary of the Society, Water Lane, Queen Victoria Street, E.C.4.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THIS week the House of Commons debated the Scottish Estimates, the Board of Trade Estimates, and the Alternative Prayer Book Measure. The House of Lords took the Committee stage of the Equal Franchise Bill.

### National Health Insurance Bill.

In moving the second reading of the National Health Insurance Bill, on June 7th, Lord GAGE, on behalf of the Government, said it was an agreed measure between the two parties chiefly concerned. It would be folly for the Minister to ride roughshod over the susceptibilities of insured persons, or of the medical profession, who administered the scheme. Most of the criticism against the bill was not directed against what it did, but against what it did not do. The bill was based on the recommendations of the Royal Commission of 1924. If it became law the Government would introduce a consolidation measure at the first opportunity. Running over the bill, Lord Gage said Clause 1 provided that a certificate from an employment exchange that a man was genuinely unemployed would entitle him to the same benefits as if he was having his card regularly stamped for a period of one year and nine months and up to a further period of one year on a reduced scale. Clause 11 of the bill provided for the setting up of a special insurance section of the Deposit Contributors Fund by which insured persons who were unable to obtain admission to an approved society by reason of ill health could obtain all the normal benefits of the Act on a basis of mutual insurance, instead of being restricted, as hitherto, to such benefits as could be provided out of their own contributions. That amounted to creating a new society for bad lives, which in certain circumstances was to be helped from the Central Fund. Clause 16 empowered the Minister to make regulations for administration of additional benefits such as dental and ophthalmic treatment. About £4,000,000 a year was now spent by approved societies on additional benefits of this character. The Minister should be able to make regulations to secure that this sum was administered to the greatest advantage of the insured person. These benefits would be administered by co-operation between the approved societies and the dentists or other professional bodies. The bill made possible the giving of dental and ophthalmic treatment in suitable cases through clinics, but expressly laid down that insured persons were to have complete freedom of choice of practitioner or clinic. If at any time any of these benefits became statutory normal benefits available to all insured persons, their administration would be transferred to the Insurance Committees or other local bodies responsible for the administration of medical benefit. Clause 20 brought within the scope of health insurance and contributory pensions small contractors themselves engaged in manual labour, and fishermen. Lord Gage remarked that the bill was not a final solution. There had already been seven or eight amending Acts of a major character since the original Act was passed, and there would be many more. The conditions affecting health, such as the housing situation and the employment situation, continually varied. The unification of the public health services was an object to be desired, but unification could only be obtained by a modification of the laws affecting a large number of subjects—factory administration, the Workmen's Compensation Acts, the Education Acts, and a considerable proportion of the Poor Law administration. In view of the imminence of Poor Law reform and for other reasons Mr. Chamberlain took the view that the time had not come for the transference of the duties of local insurance committees to county and borough councils. This would be only an instalment of the unification plan, and such unification should not be carried out piecemeal. Mr. Chamberlain would have liked the adoption of the Royal Commission's recommendation that the surpluses of approved societies should be partially pooled to enable specialists' services to be made a statutory benefit. In the bill these were legalized as an additional benefit. The suggested pooling was the only method whereby the necessary funds could be obtained for financing such a scheme without recourse to the Exchequer. The approved societies had, however, so set their faces against this method that Mr. Chamberlain had been prevented from making this necessary and desirable extension. Apart from these omissions the bill carried out many of the recommendations of the report. It would remove many considerable grievances and would simplify administration. The extent to which it encroached on public funds was small.

Lord GORELL said the bill was solely concerned with minor alterations in machinery. As such it was to be welcomed, but it was also to be criticized because it was so limited. He regretted that there had been no advance in ensuring specialists' services, and that the question of maternal mortality had been left wholly untouched. Something more should have been done to emphasize the need for attendance in maternity cases.

Lord BEAUCHAMP said the bill was complicated and technical. The majority of the Royal Commission made 122 recommendations, of which the bill only contained 32. The chief things the Commission recommended were an extension of sick benefits to the dependants of insured persons, the provision of maternity

benefits, and the establishment of a new service under which an insured person might have the attention of a specialist and dental treatment. Not one of those promises had been fully redeemed. He did not know anything more important to-day than the question of maternal mortality. No attempt had been made to return to the insurance funds the money taken from them by the Act of 1926. The total amount available for investment by these societies in 1925 was £8,000,000. Last year they only had £200,000 left to invest. He hoped Lord Gage would represent to Mr. Chamberlain that the House of Lords desired an amalgamation of the whole system of insurances into one organic and complete whole.

Lord COZENS-HAANZ regretted that the Government had not the courage of their convictions in favour of extensions of medical benefit which were urgently necessary, particularly that of specialists' services. He hoped that after the general election the Government would tackle this question, and also the vexed question of co-ordination of the health services of the country. Under the present arrangements for medical benefit the Insurance Committee had to set up statutory subcommittees to investigate the services included in medical benefit, doctors or chemists. These medical and subcommittees did very useful and important work. Complaints of this nature could only be investigated satisfactorily locally. He asked Lord Gage to give some assurance that provision for similar machinery for investigating complaints in regard to any such local services would be made, whether those services were statutory or additional benefits. In particular he hoped Lord Gage would give some assurance that insurance committees would be required to set up a dental service subcommittee on the same lines as the medical service subcommittee.

The bill was read a second time without a division and referred to a committee of the whole House.

### Scottish Board of Health Estimates.

In Committee of Supply, on June 11th, the House of Commons debated the policy of the Scottish Board of Health, on an estimate for £2,037,515 to defray the charges for salaries and expenses of the Board, housing grants, and grants-in-aid for the Highlands and Islands Medical Service.

Mr. E. BROWN opened the discussion by raising the question of slum clearances. He said that careful investigations had been made by some cities. Edinburgh was engaged in a very exhaustive examination, and preliminary figures showed that there were 5,000 houses in that city alone which should be marked down as unfit for human habitation. The real problem of slum clearance had not yet been begun to be touched in Scotland.

Mr. J. STEWART said that in Glasgow to-day 6,000 people were suffering from tuberculosis. Of those so suffering who were living in one-apartment houses, only 57 have a room to themselves; 145 have a bed to themselves, though living in the same apartment with others; 976 were sleeping in a bed with other people. In two-apartment houses the story was the same. There were 441 with a room to themselves, and 2,506 sleeping in beds with others. Out of 3,415 cases, fewer than 1,000 had either a bed or a room to themselves. Could they wonder that tuberculosis still persisted? To-day, in Glasgow, they were facing the erection of another sanatorium for 400 patients which, before it was finished, would have cost something approaching £500,000. To provide a separate bed for over 5,000 consumptive patients would require an annual addition of 1,350 houses. Surely the Government could do something to give the local health authority the power to provide sleeping accommodation for these people, and to provide a separate room for a person suffering from this disease. Glasgow, with a population of 1,250,000, still had 13,000 houses which were unfit for human habitation. The problem was so insurmountable and the cost involved so enormous, that the local authorities, and the medical officers representing them, were afraid to face the task of making the necessary investigations.

Mr. MACPHERSON said that one of the very best instruments that had ever been introduced into the medical service of any country was the Highlands and Islands Medical Service in Scotland, but in the estimates the amount annually allocated for that service was only £42,000. The very special work which this did not be done for £42,000 a year. He said that the Government intend to do to keep this fund solvent? The Northern Infirmary at Inverness was in a unique position. Was it the intention of the Government to give an additional grant to the Northern Infirmary, which provided the one great institution for almost all types of cases in that broad and scattered district? There was no other institution like it in the North. It was impossible for people who were suddenly taken ill, and had possibly to be operated upon quickly, to endure the long journey to the better-known infirmaries of Edinburgh and Glasgow, and it had become necessary, in the interests of humanity and of the Highlands as a whole, that this should become a really first-class institution. It would require a complete staff of specialists. The doctors and surgeons of Inverness were at the top of their profession, but they wanted all the recent appliances of science, medicine, and of surgery, and the infirmary ought to be properly equipped and maintained. They could not get that unless they had a permanent grant from the Board of Health, from the Government, or from the Highlands and Islands Medical Service Fund.

Dr. DRUMMOND SMELLS said that he agreed as to the very excellent nature of the report of the Scottish Board of Health. It was always a mine of information, and it would be fitting at that time to pay tribute to the valuable work that had been

done in connexion with it by Sir Leslie MacKenzie, who had now retired, but who had been responsible for some very important sections of the report for a good many years. He was glad to see that the question of river pollution was being taken up seriously by the Board of Health. There was no doubt that both on aesthetic and health grounds that question was of considerable importance. In regard to tuberculosis, it was a matter for regret that the progressive fall in the death rate was not maintained during the last year, but probably the reason given in the report—the very severe climatic conditions in Scotland last year—might be part of the explanation. Undoubtedly they were still retaining in some of the houses in Scotland many cases in an infectious stage, and in so far as they did that they were really wasting public money spent in other efforts to get rid of the disease. He was glad to notice that there was a slight fall in the death rate from non-pulmonary tuberculosis. In that connexion were the Board of Health quite satisfied that all that was possible was being done with regard to the milk supply? The milk supply in Scotland for a good many years was responsible for a considerable number of cases of non-pulmonary tuberculosis. They had had, in recent years, the licensing system, with tuberculin-tested and graded milk, and so on, and there was no doubt that this had provided milk which was a great improvement on any supplied before. But it had to be remembered that licensed milk was dearer in price, and he was anxious to know whether the average of the non-graded milk was not perhaps lower than before the graded system was instituted. It was of great importance that continued attention should be devoted to securing a pure milk supply.

He agreed with Mr. Macpherson that the Highlands and Islands Medical Service had done a very great work. He was glad that the report called attention to the very serious position in regard to tuberculosis in the Highlands and Islands. If they took the 15 to 34 age group, and looked at it in relation to Scotland generally, and the Highlands and Islands in particular, they found that the general average rate for Scotland was 12.2; for the county of Inverness, 20.5; for Ross and Cromarty (excluding Lewis), 26.9; for Shetland, 28.1; for Sutherland, 31; and for Lewis, 37.1. Those were extraordinary figures. The report said that the reason for this state of things was a matter for surmise, and that research was being conducted. Those who knew the Highlands and Islands did not need to look very far for, at least, the major causes of this condition. The first was housing; very many people in the Highlands and Islands were shockingly housed. Again, it was quite possible that some of these people did not get adequate food and were not in a position to resist disease. These figures bore out the need for the investigation which was dealt with in the House of Commons a short time ago, and it was to be hoped that general improvement in the prosperity of the Highlands and Islands would result in the reduction of these very alarming and very unsatisfactory figures.

He would like to have said something about the Hairmyers Colony, and of that method of dealing with certain types of tuberculosis. There was no doubt that such a labour colony was on right lines. The Middle Ward District of Lanarkshire and the Board of Health were to be congratulated on co-operating in this effort to deal with tuberculosis on up-to-date lines. He asked the Under-Secretary for Scotland, who was an authority on the subject, how the light treatment for surgical tuberculosis was proceeding. Did he consider that the facilities for that treatment, which it was now admitted was very successful in these cases, were satisfactory? In the report, reference was made to the number of dispensaries being fitted up with light equipment. The references to venereal disease in the report were also very interesting. They dealt with the general propaganda methods which were undertaken with the encouragement of the Board of Health, and also with the possibility of preventive methods. They said, in regard to those, that certain preventive methods might be contributory to the spread of the disease. He thought he had heard an echo of that in other quarters. It was not the opinion of the army and navy. The army and navy had reduced their figures in connexion with these diseases by the methods which were so sceptically referred to in the report. The Trevelyan Committee also favoured them. He was interested to find that the Board came to the conclusion that secrecy, which was so much stressed in the debate in that House a few weeks ago, did not seem to be of great importance, at least as regards the great cities. One could see quite well that while the language used was guarded, the Board of Health, as they had shown on several occasions before, were not convinced that the present arrangements and systems were satisfactory or capable of dealing adequately with these serious diseases. This certainly justified the attitude of the Edinburgh Corporation and other Scottish local authorities in the matter. It was an appalling fact that last year in Scotland the number of defaulters was 51 per cent. In view of the very large amount of public money spent in dealing with this subject, it was obvious that a great deal of that money was wasted and, in the name of economy, if humanity was not enough, something else should be tried.

There was a return in the report to the attack made last year on the medical profession in regard to certification of people as unfit for employment. He had hoped that they had heard the last of that, because, in his opinion, that attack, while it might have been justified in some cases, had been overdone. Altogether, an attitude was being taken up in regard to the medical profession, and incidentally in regard to their patients, which was quite unjustifiable. The report did not sufficiently recognize that the condition of the people in Scotland during the past few years had been such, owing to unemployment, that they were more liable than formerly to illness. It was unfortunate that by means of threats and talk of surcharges, and referees, and so on, medical men should have it suggested

to them that they should cut down prescribing to the very minimum amount. He had never seen or heard of any investigation to find out if medical men were supplying sufficiently good medicines, tonics, and building-up preparations, which were often necessary. So long as the medicine was cut down, and the cost of prescribing was low, there was evidently no worry as to whether the insured person was getting proper remedies. The whole tendency of the system was to cease the doctor to be afraid to give what, in many cases, would only be adequate for the nature of the case.

Sir R. HASTINGS also drew attention to the enormous value of the work of the Highlands and Islands Medical Service Fund. He said he did not believe that the annual contribution to the Fund of £12,000 a year had been increased to meet the change in money values, but the Fund was expected to do the same work to-day, when costs were infinitely higher, as in 1913. There was probably no fund in the world more economically administered, and which did a greater amount of good. In a short time, unless a further contribution was made, the work of the Fund could not be carried on, and it would have to come to an end in eighteen months. He had it on the best authority that another £25,000 a year was required. He asked for an assurance from the Government that provisions would be made so that the work of the Fund should not be allowed to be diminished. A branch of the work which had been an outstanding success had been the appointment of consulting surgeons in the outer islands. In Shetland, particularly, where a most excellent surgeon was appointed, the result was that operations of importance could be performed in cases which would otherwise have had to be sent south. As a result, patients were got under treatment early, and the hospitals in the south, whose beds were too full already, had been relieved.

Mr. SCRYMGEOUR, referring to venereal disease, said that the Scottish Board had issued an excellent compendium of information on the various activities of the department, but in regard to this terrible disease it put in veiled language evidence that it would like to do something better, but was being held back on account of the position of the English Ministry of Health. That situation once more proved the futility of trying to do anything in that connexion at all.

Sir A. SINCLAIR, emphasizing what Dr. Shields had said about harrying doctors for over-prescribing, said that there had been cases in his constituency of well-known and very much respected doctors who were accused of over-prescribing. They were most careful men, who held important public positions in the country, and men regarding whom such an accusation could not for a moment be entertained by those who knew them. He hoped that this action would not be resorted to in future. He asked for an assurance from the Government that the efforts of the local people to maintain and improve the equipment of the Bignold Hospital in Wick, and the Dunbar Hospital in Thurso, would be supported, and, in particular, that they would be able to obtain the much-needed services of a surgeon.

Mr. STEPHEN complained about a paragraph in the report of the Scottish Board of Health dealing with the certification by doctors under the national health insurance scheme. He challenged the implied reflection in it that doctors in Scotland were allowing people to draw sick benefit who were not entitled to it. It was obvious that the paragraph was written to try to terrorize the timid members of the profession into sending people back to work before they were fit to return, or to keep them from giving certificates to members of the working classes who, through being unemployed and consequently unable to get proper food, had got into an unhealthy condition.

Dr. ELLIOT, replying to the debate, said that Mr. Stephen had spoken of reflections and attacks on the medical profession contained in the report. The spectacle of Mr. Stephen defending the medical profession against the attacks of Sir Leslie MacKenzie was one that they might well leave to the delighted laughter of the medical profession in Scotland. Continuing, Dr. Elliot said that there were many houses in Scotland which they not only regarded as unfit for human habitation, but which their fathers and grandfathers would have classified as unfit. Those were the houses that the Board of Health wished to get rid of in the first place, but until they made a beginning with them it was useless to reclassify houses, and say that no houses were satisfactory unless there were three rooms with bathroom, water-closet, and other modern conveniences. They had done their utmost to impress on the local authorities, who were building houses, that people at present were suffering acutely not only from unsatisfactory houses, but from overcrowding. A cut had taken place in the English housing subsidy, but none in that for Scotland, and they had the assurance that none would be made until March 31st. The subsidy for the Highlands and Islands Medical Service would have to be considered. It was now £12,000 a year, but the Fund was drawing on its unexpended balances to make up an expenditure of £62,000 a year. The Secretary of State would again approach the Treasury, and he had no doubt that he would succeed in getting a substantial increase in the statutory rate of that subsidy. The report of the Scottish Board of Health was a review of the work of the local authorities. It pointed out many directions in which that work needed to be expanded, and in which it could be greatly advantaged by a better system of co-operation among the local authorities. All these things were being brought up, considered, and dealt with in the great financial measures now before Parliament.

The debate was adjourned.

[Various other matters connected with medicine were discussed in Parliament this week, but the pressure on our space compels postponement of further reports.]

## Medical News.

THE annual general meeting of the Research Defence Society will be held at the House of the Medical Society of London, 11 Chandos Street, Cavendish Square, W., on Tuesday, June 19th, at 3 o'clock. The chair will be taken by the President, Lord Lamington. An address will be delivered by Sir Bernard Spilsbury on "The work and responsibilities of a pathologist," being the second Stephen Paget Memorial Lecture. Tea and coffee will be served after the meeting.

A MEETING of the Tuberculosis Association will be held on June 22nd, at 8 p.m., at the house of the Royal Society of Medicine, 1, Wimpole Street, W. Dr. F. R. Walters will read a paper on the causes of breakdown in health in pulmonary tuberculosis.

THE National Council for Mental Hygiene has arranged a public meeting, to be held in the Council Chamber, Birmingham, on Thursday, June 21st, at 5 o'clock, when addresses on the prevention of nervous breakdown will be given by Sir Maurice Craig and Dr. H. Crichton Miller. The chair will be taken by the Lord Mayor of Birmingham.

DR. ARTHUR HOPEWELL-SMITH will give a lecture, entitled "The process of osteolysis: a histological study," at Gay's Hospital on June 26th at 4 o'clock.

THE annual meeting of the British Hospitals Association will be held in the Congregational Schools at Southport on June 21st and 22nd under the presidency of Sir Arthur Stanley. Sir Thomas Horder will open a discussion on the place of the voluntary hospital in relation to health services, and Mr. G. Q. Roberts, secretary of St. Thomas's Hospital, will open another discussion on the problems of the voluntary hospital to-day compared with those of the past. Miss M. E. Sparshott, lady superintendent of nurses, Manchester Royal Infirmary, will open a discussion on the place of the nurse in the hospital. Further information may be obtained from the secretary of the conference, Mr. J. H. Shaw, Southport General Infirmary.

THE twenty-first anniversary dinner of the Royal Society of Tropical Medicine and Hygiene will be held at the Café Royal, Regent Street, W.1, on Wednesday, June 20th, at 7.30 p.m. for 8 p.m., under the chairmanship of Professor J. W. W. Stephens, M.D., F.R.S., President of the Society. Applications for tickets should be made to the Assistant Secretary, 11, Chandos Street, W.1.

THE Cambridge Graduates' Medical Club will hold its annual dinner in Pembroke College on Saturday, June 23rd, at 7 o'clock, with the president, Sir Humphry Rolleston, in the chair. The annual meeting will precede the dinner. Dr. V. C. Pennell, Westfield, 28, Huntingdon Road, Cambridge, is acting as local secretary.

THE Fellowship of Medicine announces that Mrs. Tindal-Robertson will give a clinical demonstration, for women graduates only, at the South London Hospital for Women, Newington Causeway, on June 20th, at 10.30 a.m. Mr. E. D. D. Davis will give a clinical demonstration in the Ear, Nose, and Throat Department of Charing Cross Hospital at 11 a.m. on June 22nd, and at 3 p.m. on the same day Mr. Dorrell will

at Eyo Hospital, Southwark. These are free to medical practitioners. Three courses begin on June 18th—namely, one in diseases of the chest at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, another in gynaecology at the Chelsea Hospital for Women during the afternoons and some mornings, and a course in medicine, surgery, and the specialties at the London Temperance Hospital from 4.40 to 6 p.m. From June 25th to July 21st the West End Hospital for Nervous Diseases will hold a special course of clinical demonstrations from 5 p.m. daily for the four weeks. The following special courses will take place in July: medicine, surgery, and the specialties at the N.E. London Post-Graduate College (Prince of Wales's General Hospital), Tottenham, all-day instruction, and a week's course in proctology at St. Mark's Hospital. Particulars of all special course syllabuses, a specimen copy of the *Post-Graduate Medical Journal*, and details of the general course of work available for those unable to do whole-time study are obtainable from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE paper read by Sir Leonard Rogers before the Section of Epidemiology and State Medicine of the Royal Society of Medicine, on the incidence and spread of cholera in India (reported in the *Journal*, May 1st, 1926, p. 784) has been reprinted from the *Proceedings* of the Royal Society of Medicine, as a memoir (No. 9) in connexion with the *Indian Journal of Medical Research*. This memoir also includes articles by Sir Leonard Rogers on cholera in the Punjab, the

Central Provinces and Berar, and in the Bombay and Madras Presidencies, the United Provinces, Bihar and Orissa, Lower Bengal, Assam, and Burma. It may be obtained from the Indian Research Fund Association, Calcutta, price 7s. net.

A CONFERENCE of delegates from various educational bodies and other organizations was held in London on June 6th to consider the higher education of the deaf. Lord Charwood, president of the National Institute for the Deaf, was in the chair, and various speakers described the existing provision and suggested improvements. Mr. W. Carey Roe said that there was no public provision for the post-primary education of the deaf, and outlined a scheme for the creation of a residential college, with facilities also for securing the co-operation of existing colleges or technical institutions. The conference resolved "that the time has arrived for the extension of the national system of education for the deaf by the establishment of provisions for further education than can be given in the present schools for such children," and decided to ask the National Institute to set up a committee to consider the proposals put forward and to report to a further conference to be held later.

THE report of the Home Service Ambulance Committee of the Joint Council of the Order of St. John and the British Red Cross Society for the first quarter of the year contains, in addition to the usual statistics regarding work done, some interesting practical notes on the care and maintenance of ambulances which should receive the attention of all concerned in this important service. It is pointed out that the comfort of patients depends largely on the condition of the cars, and it is suggested that divisions and detachments of the organizations should make it their business to remedy all structural defects which may develop. Referring to the road service scheme adopted last year, which was described on April 7th (p. 603), the report records an appreciable extension in the number of roadside first-aid boxes, first-aid stations, and patrols all over the country. Last year it was noted that the presence of uniformed members of the Order and the Society on the roads served as a warning to many drivers and pedestrians of the need for caution. The committee suggests that units undertaking work on the roads should forward to the headquarters of their organizations descriptions of the schemes of working adopted and any observations on their experience, so that information may be made available for the guidance of those taking up the work for the first time.

DR. CHARLES GORDON MOORE has been appointed physician-in-ordinary to H.R.H. Princess Beatrice in succession to Sir Alfred Rice-Oxley, resigned.

DR. WILLIAM BLACK JONES, J.P., Bulth Wells, has been admitted a serving brother of the Order of the Hospital of St. John of Jerusalem.

At a recent meeting of the Straits Settlements Legislative Council a bill was read for the first time designed to grant authorization to medical practitioners and certain other persons to possess and use dangerous drugs without licence, so far as it is necessary for the practice of their profession or employment, in the same degree as is lawful in England.

THE Hong-Kong Medical Association gave a dinner on April 21st to European practitioners and their friends; the Governor, Sir Cecil Clementi, was present. Dr. Jen Hawk, the chairman of the Hong-Kong Chinese Medical Association, welcomed the guests, and Dr. Lee Shu-fan, who proposed their health, expressed the hope that there would be still closer co-operation between Chinese and foreign medical practitioners in Hong-Kong. He recommended more adequate medical staffing of some of the local Chinese hospitals, and suggested that the appointment of a full-time European medical officer, together with the arrangement of the medical services in departments, would be very beneficial. The Governor, replying, discussed the hospital organization of Hong-Kong, and, while refraining from defining any policy, agreed that it might be very desirable if representatives of the British and Chinese Medical Associations had seats on the medical board and the midwives board. The toast of the British Medical Association was proposed by Dr. Phoon Seek Wah, and, in reply, Dr. S. S. Strahan spoke of the necessity of upholding the high standard of Western medicine and of increasingly close co-operation with Chinese practitioners. Over 100 medical practitioners were present.

THE centenary of the birth of the celebrated obstetrician Etienne Tarnier has recently been celebrated in Paris at the Hôpital Tarnier and Académie de Médecine.

THE following appointments have recently been made in foreign faculties of medicine: Dr. Spiethoff, professor of dermatology at Jena; Dr. Steinhauser, professor of physiology at Greifswald; and Dr. Tanon, professor of hygiene and preventive medicine at Paris in succession to Professor Léon Bernard, who has been appointed the first occupant of the new chair of tuberculosis.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are MUSEUM 9561, 9562, 9563, and 9564 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the *British Medical Journal*, Aitiology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westcent, London.

MEDICAL SECRETARY, Mediscera Westcent, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Pacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

### QUERIES AND ANSWERS.

#### WHOLE BLOOD TRANSFUSION.

DR. OSBORNE BROWNE (Jamaica) writes: Can consanguineous blood—that is, parents and children, brothers and sisters—be used without grouping and without risk? What is the simplest method of grouping without the aid of a microscope? Sometimes one would like to transfuse at short notice and in out-of-the-way places, but the fear of group incompatibility acts as a deterrent.

#### CRAMP AFTER SCIATICA.

WITH reference to the note by "F. W. S." on the treatment of cramp after sciatica, on March 24th (p. 534), it may be added that the preparation employed was "iodolysin," obtainable from Messrs. Allen and Hanburys, Ltd.

#### INCOME TAX.

##### Payments for Capital Borrowed.

"E. K. S." has borrowed capital to pay out his late partner and is paying, *inter alia*, interest, from which he deducts income tax, and an annual sum representing the cost of a fidelity policy. How should he deal with these payments?

\* \* So far as the interest is concerned it cannot be deducted as an expense, and therefore is assessed on "E. K. S." (as part of his profits) as if it were his income, except that tax is payable on that portion of the profits at the full standard rate. In that way the tax deducted by "E. K. S." reaches the Revenue without any specific *ad hoc* payment being made. The fidelity policy payments relate to a capital charge and are not allowable as expenses, though presumably they are part of the company's profits and are assessed to tax accordingly.

##### Commencement of Partnership.

"J. K. S."—A and B have worked together for some years, B being a "salaried partner." A deed of partnership was executed in January, 1928, "dating the partnership back to January, 1927." The income tax authorities will not admit that a partnership existed prior to January, 1928.

\* \* "Partnership" is a special relation between the parties, and the deed of January, 1928, cannot have constituted that relation in 1927, though, of course, it was open to A and B to enter into any arrangement with regard to the payments to be made to B for his work in 1927. "J. K. S." refers to B's earlier status as that of a "salaried partner"; we are not quite sure what precise meaning should be attached to that description, but assume it to mean that B was a salaried assistant with a share in the firm in prospect. If so, then we think that the additional payments made to him for 1927 as a result of the partnership deed may properly be regarded as his remuneration for that year, and be charged on him under Schedule E, and treated as expenses in the accounts of the practice.

##### Depreciation Allowance—X-Ray Apparatus.

"F. P. D." states that his claim to a depreciation allowance has been refused, the inspector of taxes stating that he is entitled only to renewal expenditure.

\* \* We do not agree. In our opinion the apparatus comes within the category of "plant and machinery," as distinct from such equipment as "tools," and therefore can properly be made

the subject of a depreciation claim. So far as our knowledge goes, that view is accepted generally throughout the country. There is no prescribed rate of depreciation; we should suggest 10 per cent. on the written-down value as being at least fair to the Revenue.

"G. A." inquires what would be a reasonable percentage for depreciation, and whether the value of articles liable to frequent renewal—such as x-ray tubes, rubber gloves, etc.—should be excluded?

\* \* We suggest, somewhat tentatively, 10 per cent. We are of opinion that when renewal takes place through obsolescence the unexhausted value can be claimed for, and thereby any insufficiency in the depreciation allowance ultimately corrected. Articles which form an integral part of the plant should be included in the value, even though subject to fairly frequent renewal—as, for instance in the case of motor car tyres; other articles, such as rubber gloves, are not proper subjects for the depreciation allowance.

##### Liability for Board and Lodging.

"K. I." was engaged as an indoor assistant in 1921 at a salary of £403. "For income tax purposes the inspector of taxes put down the income as £500 per year." Is he legally entitled to claim the tax paid in error?

\* \* No, any legal right could have been preserved only by lodging formal notice of objection to the incorrect assessments when they were notified. But if "K. I." can make it clear that the inspector of taxes knew that the salary was £400 and added the £100 for board and lodging through an official error as to the law applicable it may be worth applying to the Board of Inland Revenue, Somerset House, W.C.2, for relief as an act of concession.

### LETTERS, NOTES, ETC.

#### COMPLETE OBLITERATION OF THE VAGINA.

DR. F. BUNJE (Hong-Kong) writes to record the case of a Chinese woman, aged 23, who was admitted to St. Paul's Hospital, Hong-Kong, with the following history. Eighteen months ago, when about five months pregnant, abortion started. At the time she was living in the interior of China, and the old women of the village were called in to attend to her. They evidently did not think that things were as they should be, and proceeded to remove the foetus by means of "metal hooks." There was a considerable amount of haemorrhage, and the patient was taken to a Chinese doctor, who proceeded to repair the damage. The patient had never menstruated since the abortion. On examination of the place where the vaginal orifice should have been, there was found a hard mass of scar tissue at the bottom of a depression, with radiating scars towards the labia. No opening could be found, even with a very fine probe, and the uterus could not be felt per rectum. There had also been extensive damage to the perineum. At the subsequent operation performed by Dr. Bunje he found that a fibrous cord of scar tissue represented the original vagina, and this was traced up to a small atrophied uterus. The cicatricial tissue on dissection was shown to lie as a partition between rectum and bladder.

#### UNUSUAL PIGMENTATION OF SCALP.

"X. Y. Z." writes: As the possessor of a "pobald" scalp I read Dr. Walker's letter, with Dr. Haldin-Davis's comments, on this subject in your issue of February 11th (p. 243) with great interest, and was surprised to learn that the abnormality is considered so rare. However, I let the matter drop. But in reading Dr. Cooper's note of May 12th (p. 832) my interest was again aroused, and this time to a very high degree, by his reference to a case in Edinburgh (my native place) twenty-five years ago; I have little doubt that I am the person mentioned. From the scientific point of view I am sorry to say that I can no longer offer myself as an interesting pathological specimen, alopecia having invaded the region in question almost to the entire exclusion of the black patch. Since my younger days other anomalies in the distribution and permanency of pigmentation have manifested themselves, but that on the scalp was present and unvarying from infancy. While the area was somewhat larger than Dr. Cooper stated, I must congratulate him on the accuracy of his description after all these years.

#### IMMUNITY FOLLOWING HERPES.

DR. H. WILLINGHAM GRILL writes: The personal experience of one of our profession may itself be worth adding to the record of Dr. James Taylor (May 26th, p. 920). About twenty-five years ago I had an attack of typical herpes zoster. Last year I had a bad bout of herpes fronsalis. Of both I bear the scars.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 70, 71, 72, 73, 76, 77, and 78 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 74 and 75.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 263.

# Results OF A SERIES OF GASTRIC AND DUODENAL OPERATIONS.\*

BY

F. J. STRONG HEANEY, M.D., F.R.C.S.I.,  
LECTURER IN CLINICAL SURGERY, UNIVERSITY OF LIVERPOOL.

In spite of the work which has been done and the volume of literature which has accumulated during the last twenty-five years there are many points still unsettled in the surgery of gastric and duodenal ulceration, and every surgeon is in duty bound to review his cases in the light of current literature and to bring his experiences, great or small, into the common stock. This must be my apology for recording the end-results in a comparatively small series of cases.

Excluding malignant disease, I have notes on 183 consecutive cases operated on by myself, mostly within the past four years, and I have endeavoured, with the assistance of my friend Dr. Aiden, to follow up every case. We have succeeded in obtaining the end-results in about 90 per cent. of them. Pathologically the cases may be classified as follows:

1. Acute perforations	...	...	...	...	33
2. Chronic duodenal ulcer	...	...	...	...	65
3. Chronic gastric ulcer	...	...	...	...	85

Total ... .. 183

I shall take the different categories in the order set forth.

## ACUTE PERFORATIONS.

I have had 33 cases, 15 gastric and 18 duodenal; the procedure followed was to repair the perforation, insert a pelvic drain, and, if the patient's condition permitted, perform a gastro-enterostomy. Gastro-enterostomy was in fact performed in 31 out of the 33 cases. Of the 33 cases 7 died in hospital, but I cannot discuss the immediate mortality in relation to the number of hours which elapsed between perforation and operation as my notes are incomplete on this point. A summary of the results is as follows:

Died in hospital	...	...	...	...	7
Good end-results	...	...	...	...	17
Good but recent (under one year)	...	...	...	...	4
Unsatisfactory	...	...	...	...	2
Untraced	...	...	...	...	3
Total	...	...	...	...	33

Of the cases in which gastro-enterostomy was performed I have been able to obtain the end-results over one year in 19 cases. In all cases save one the result was good. In that one the stoma became inadequate and symptoms recurred. At a second operation the stoma was enlarged, and thereafter the course of the case was satisfactory.

In two cases gastro-enterostomy was not performed because of the patients' condition—one a duodenal and the other a gastric case. In the duodenal case I learnt at the follow-up that he was admitted later into another hospital for duodenal symptoms, which were relieved by gastro-enterostomy. In the stomach case the perforation which I was called on to treat was a second perforation; the first occurred five years previously, and had been treated elsewhere without gastro-enterostomy. On opening the abdomen the viscera were matted together by adhesions and the patient's condition was so serious that I did not subject him to the strain of a gastro-enterostomy, an addition which would have involved the separation of many adhesions. This case is, of course, liable to a further repetition of ulceration and perforation. I do not know whether in the duodenal perforation which was repaired without gastro-enterostomy, and which required a gastro-enterostomy later at another hospital, the operation was embarrassed by similar adhesions. Of the two unsatisfactory end-results, therefore, one had no gastro-enterostomy, the other an inadequate gastro-enterostomy.

I shall not repeat all the arguments for and against gastro-enterostomy, but will merely say that in so far as my own experience goes I find myself in agreement with

those who believe in taking the risk of the extra fifteen minutes required for a gastro-enterostomy unless there are definite contraindications.

## CHRONIC DUODENAL ULCER.

I shall next refer to the cases of chronic duodenal ulcers. There are three schools of thought as to the manner in which this condition should be treated. (1) Those who follow what I believe is the practice of the great majority of surgeons—performing gastro-enterostomy and removing any septic focus, such as the appendix. (2) Those who, accepting Lewisohn's figures as to the high incidence of gastro-jejunal ulcer, and the tendency to neutralize or diminish and practise an extensive gastrectomy. In this country Moynihan's practice, I believe, is an approach to the position of this school. (3) Those who accept Lewisohn's figures but regard gastro-enterostomy as an unjustifiably severe routine remedy for duodenal ulcer, and who have therefore abandoned surgical treatment altogether. Lally of Baltimore takes this extreme view, and no one can doubt his sincerity. His well-known clinic is organized for surgery, but he passes all his cases of chronic duodenal ulcer on to a "gastrologist"—an expert in the practical application of the Sippey diet as combined with alkalis. With increased experience of this procedure he seems to have become more convinced of its soundness.

In all my cases I have followed the more usual line of treatment—namely, gastro-enterostomy. At first I only removed the appendix when it was definitely pathological; now I remove it when there is the slightest suspicion of past or present inflammation, and where the patient's condition permits. The results may be summarized as follows:

Good end-results	...	...	...	...	24
Good but recent (under one year)	...	...	...	...	29
Unsatisfactory	...	...	...	...	6
Untraced	...	...	...	...	4
Died in hospital	...	...	...	...	2
Total	...	...	...	...	65

The details of the six unsatisfactory end-results were as follows:

In one (37) a gastro-jejunal ulcer formed after an interval of four years. It was cured by partial gastrectomy (anterior Polya). In one (65a) a gastro-jejunal ulcer formed after an interval of three months. It was cured by partial gastrectomy (anterior Polya).

In one (74) the stoma was found to be functioning unsatisfactorily. It has not yet been explored.

In one (43) there is definite chronic appendicitis.

In two others (41 and 29r) the complaints made were slight but suggested chronic appendix trouble. The patients have not yet presented themselves for further investigation.

In none of the six cases had appendicectomy been carried out at the original operation.

It will be noted that in the previous group—the acute perforations—there were no late symptoms of appendix trouble, although in none of them had appendicectomy been performed.

Various writers have figured the x-ray appearances in gastro-jejunal ulcer, but as the condition is not always radiographically demonstrable it may be of interest to show two x-ray photographs (Figs. 1 and 2 in one of the above-mentioned cases—No. 65a).

In the discussion of the causation of gastro-jejunal ulcer after gastro-enterostomy the technique of the original operation and the post-operative medical treatment have so often been held responsible for the subsequent complication that the technique employed in this series may be mentioned. A vertical or nearly vertical stoma running into the greater curvature at its lowest point is aimed at. No mucosa is removed and only absorbable sutures are used. In hospital cases, which constitute the majority of those noted and amongst which the two gastro-jejunal ulcers arose, a prolonged post-operative dietary and medication is found impracticable.

The percentage incidence of gastro-jejunal ulcer in this series of gastro-enterostomies for duodenal ulcer works out at 3.3. While dealing with this group I would like to allude to the condition of acute duodenitis and gastritis which sometimes arises as a complication of chronic duodenal ulcer, and to cite three cases of this kind encountered within the past few months. The condition has

\* A paper read before a joint meeting of the Manchester Medical Society and the Liverpool Medical Institution on March 7th, 1928.

been alluded to by Judd in one of his contributions to the literature. One of my patients, a stout man with a long history of recurring duodenal symptoms, had, when I first saw him, continuous pain and vomiting. The pain was in the epigastrium, and he vomited large quantities of clear brown fluid although only taking sips of water. At operation the duodenum was red, oedematous, and adherent to the liver. The redness extended beyond the duodenum over the lower half of the stomach. The main feature of the case was the incessant vomiting, a picture not unlike the acute alcoholic gastritis one saw before alcoholism became a rarer vice. In spite of the duodenum becoming detached from the liver and its lumen being exposed in the course of the gastro-enterostomy he made a good recovery.

FIG. 1.

FIG. 2.

FIG. 1—Drawing from 3-ray photograph in Case No. 65a. Showing retraction of outline of greater curvature at site of stomach and projection of gastro-jejunal ulcer beyond the line of the greater curvature.

FIG. 2—Drawing from 3-ray photograph of same case as Fig. 1. Showing residue six hours after barium meal and projection of the gastro-jejunal ulcer.

My other two cases were somewhat similar in clinical features and pathological findings. In one of them the vomiting was so severe as to cause a secondary acetonaemia, and operation had to be delayed some days while the patient was treated with glucose rectally. In this case the slight traction employed in bringing up the stomach for gastro-enterostomy caused the rupture of an abscess and a flow of pus from the point where the falciform ligament, the liver, and the inflamed duodenum came together. Drainage was required, but the patient made a good recovery.

In all three cases there had been a long-standing duodenal history and the acute condition had supervened rather suddenly. One patient, x-rayed at the end of November, showed no radiological evidence of duodenal trouble; nevertheless in the three or four days following Christmas he rapidly developed the acute symptoms described. It is well recognized that a duodenal ulcer can evolve from the quiescent stage to perforation. It can with even greater rapidity develop an acute duodenitis and gastritis. Pyloric spasm doubtless plays a part in the incessant vomiting.

The only other point on the subject of duodenal ulcer to which I will allude is the unsatisfactory nature of x-ray diagnosis in minor degrees of the condition; it is fortunate that the clinical history and symptoms are as a rule more characteristic. In not a few cases, however, where the clinical symptoms and the x-ray appearances suggested duodenal ulcer I have opened the abdomen and found a doubtfully pathological appendix or mid-line ptosis. I have come to distrust slight irregularities in form and behaviour of the duodenal cap, and, as is well known, a six-hour remainder in the stomach of the opaque meal does not mean organic disease, especially in the presence of mid-line ptosis. Frequently the patient has to be told that both appendix and duodenum should be inspected, but that probably the operation will resolve itself in an appendicectomy. Owing to the indeterminateness of the ordinary antero-posterior x-ray picture and screen examination one must ask more frequently for side-to-side and oblique views.

The etiology of gastro-jejunal as well as of duodenal ulcer has been established on a surer foundation by the experiments of Mann and Williamson, resulting in the production of duodenal ulcers by abstraction of the bile and pancreatic fluid, and still more by the fact that Morton, applying Mann and Williamson's findings, in fresh experiments, succeeded by duodenal drainage in producing gastro-jejunal ulcers in 100 per cent. of cases.

The clinician still seeks to know what it is in particular clinical cases of gastro-jejunal ulcer which corresponds to experimental duodenal drainage—what it is in the clinical case which excludes or overwhelms the normal duodenal effect. If it is a hyperchlorhydria, what is the cause of the hyperchlorhydria? On this point we have still to fall back on theories of nervous and neuro-muscular influences, blood changes, and so forth.

#### CHRONIC GASTRIC ULCER.

I have notes on eighty-five cases of chronic gastric ulcer during the period I have taken. In this group the clinical picture and the pathological findings at operation vary so much from case to case that if the end-results are to be compared with any degree of usefulness some further subdivision is necessary. I have roughly divided the eighty-five cases into complicated and uncomplicated.

In the complicated group I have included the larger ulcers of the posterior wall, cases of chronic perforation with erosion of pancreas or other neighbouring structure, cases of multiple ulcer situated high on the stomach, cases complicated by ptosis, cholecystitis, and hour-glass contraction. For the purpose of this subdivision I have not regarded a chronic appendix as a complication.

#### Uncomplicated Gastric Ulcer.

I will take the uncomplicated cases first. In every case save one gastro-enterostomy was performed. This was combined in some cases with excision of the ulcer, in others with appendicectomy, in others with both excision and appendicectomy. In my earlier cases I did not excise small ulcers; I now excise in every case where the general condition of the patient seems to warrant the more prolonged procedure. In one case excision alone was done because a physician thought that with the aid of medical treatment gastro-enterostomy might be obviated. The result in this case was not satisfactory. The patient continued to have symptoms until she died of phthisis a year later.

Of the fifty-four uncomplicated cases operated on the following is the summary:

Died in hospital	...	...	...	...	...	2
Left hospital in good condition	...	...	...	...	...	52
Traced (less than one year had elapsed in 20)	...	...	...	...	...	50

Results in all traced cases were good, there being no difference in the result whether the ulcer was excised or not. It is to be noted, however, (1) that they were all simple uncomplicated cases, and (2) that some of them are still recent and liable to develop late complications. The immediate mortality was in each case due to post-operative pneumonia.

#### Complicated Gastric Ulcers.

In this group of thirty are roughly included all except the single small ulcer. The complicating factors here are varied and the number in any group too small to speak in percentages. I have therefore set forth the list of cases in detail (see accompanying analysis of cases). Glancing rapidly through it one sees:

*Group 1.*—Each of the first two cases showed a pyloric tumour suspiciously like malignant disease. On microscopic examination both proved to be non-malignant. One died of post-operative pneumonia, and the other shows no sign of further trouble although four years have elapsed.

*Group 2.*—The next group consists of ten large ulcers with adhesions and erosion of neighbouring organs. In six a partial gastrectomy was performed (anterior Polya). In the others the ulcer was excised and gastro-enterostomy performed. In one of these latter the ulcer recurred nine months after excision, and I was obliged to do an anterior Polya operation, with satisfactory result. In this group there was one death from post-operative pneumonia; apart from this death and the case of recurring ulcer the results were good. Figures 3, 4, 5, and 6 show the history of the recurrent ulcer.

*Group 3.*—The next is a case of a large ulcer high on the lesser curvature; the ulcer was excised and a gastro-enterostomy performed at the lowest point of the greater curvature. The end-result was satisfactory.

*Group 4.*—These are three cases of multiple ulcers. In the first case a high gastro-enterostomy was performed without excision; the result was unsatisfactory. In the second case there was an active ulcer and a quiescent one; the active ulcer was excised and gastro-enterostomy performed at the lowest point of the great curvature; result satisfactory. In the third case partial gastrectomy was performed with satisfactory end-result.

*Group 5.*—In these two cases mid-line ptosis existed in an

extremo degree. In the first the ulcer lay high; gastro-enterostomy was performed at a higher level than usual with the idea of neutralizing the region of the stomach concerned. The appendix was so obviously diseased that it was hoped to effect a cure by gastro-enterostomy and appendicectomy. The patient was a bad surgical risk, and excision was not performed. The result was unsatisfactory. In the second case the ulcer was not excised, but in addition to gastro-enterostomy a Coffey's gastro-colo-plexy with elevation of the falciform ligament of the liver was done. Although according to many authorities the treatment was unorthodox the result was satisfactory.

Group 6.—This group consists of two cases complicated by cholecystitis; the end-results were good.

FIG. 3.

FIG. 4.

FIG. 5.

FIG. 6.

FIG. 3.—Drawing from x-ray photograph in Case No. 63. An ulcer which recurred after excision and gastro-enterostomy.

FIG. 4.—Drawing from x-ray photograph of same case as Fig. 3. Showing condition three months after excision and high gastro-enterostomy. About this time symptoms began to recur.

FIG. 5.—Drawing from x-ray photograph of same case as Fig. 3. Showing ulcer re-formed nine months after excision and gastro-enterostomy.

FIG. 6.—Drawing from x-ray photograph of same case as Fig. 3. Showing end-result after partial gastrectomy performed nine months after original operation. No further symptoms to date.

Group 7.—This consists of ten cases of non-malignant hour-glass stomach. The immediate results, it will be seen, include three deaths. Although the cases were poor surgical risks the results are disappointing. In the first fatal case I had no opportunity of seeing the patient after operation, but was informed that she suddenly collapsed on the third day. In the second fatal case the patient died of pneumonia. In the third case there was persistent vomiting in spite of repeated lavage of the stomach and elevation of the bed, and when I had decided to reopen the abdomen the patient unexpectedly collapsed and died. The operation was an anterior Polya. Rightly or wrongly, death was attributed to acute gastric dilatation. Rendle Short records cases where the opposite sides of the stomach stick or grow together, and thinks it worth while to hang a rubber dam between them before completing the anterior layer of stitching. This is the only case I can recall having lost in this way, and I hardly think a rubber dam would have saved the situation.

Looking at the complicated cases as a whole it will be seen:

(1) The immediate mortality is disappointing: 3 patients died from pulmonary complications, 1 from acute dilatation of the stomach, and 1 from collapse.

(2) The end-results after a year of those that survived were as follows: All gastrectomy operations—good. All gastro-enterostomies and excisions—good, save one where the ulcer recurred, necessitating gastrectomy. Two cases of high gastro-enterostomy alone—unsatisfactory. Whether it was the high position of the stomach or the non-excision of the ulcer that was responsible for failure in the last-mentioned cases is not quite clear; I hope to have a further opportunity of investigating them. At present complaint is made of pain and flatulence, but there is some degree of improvement, and the patients are for the moment reluctant to have any further x-ray examination or treatment.

## Analysis of 80 Cases of Complicated Gastric Ulcers.

	Record No.	Condition.	Operation.	Result.
Group 1	10	Ulcer with pyloric tumour	Hillroth II	Good.
	135	Ulcer with pyloric tumour	Polya	Died (pulmonary).
Group 2	27a	Large ulcer, lesser curvature	Polya	Good.
	63	Large saddle ulcer	High G.E. and excision	Recurred—Figs. 3, 4, 5, and 6.
	78	Perforating ulcer (spleen and pancreas)	G.E. and excision	Good.
	92	Perforating ulcer (pancreas)	G.E. and excision	Good.
	97	Perforating ulcer	G.E. and excision	Died (pneumonia).
	120	Large pyloric ulcer	Polya	Good.
	123a	Large saddle ulcer	Polya	Good.
	126	Ulcer, adhesions lesser sac	Polya	Good.
	137	Large ulcer, perforating mesocolon	Polya	Good but recent (slides).
	150	Large saddle ulcer	Polya	Good but recent.
Group 3	29	Ulcer high up	G.E., excision of ulcer, appendicectomy	Good.
Group 4	47	Multiple ulcers	High G.E.	Unsatisfactory.
	85	Two ulcers (one quiescent)	G.E. and excision	Good.
	107	Two ulcers	Polya	Good.
Group 5	49	Ulcer and ptosis	High G.E., appendicectomy	Unsatisfactory.
	114	Ulcer and ptosis	G.E. and Coffey's operation	Good.
Group 6	81	Ulcer, adhesions and gall-stones	G.E., cholecystectomy	Good.
	110	Ulcer and gall-stones	G.E., cholecystectomy	Good.
Group 7	38	Non-malignant hour-glass with gall-stones	Polya; cholecystectomy; appendicectomy	Good.
	39	Non-malignant hour-glass	Polya; appendicectomy	Good.
	62	Non-malignant hour-glass	G.E.	Good.
	71	Non-malignant hour-glass	Excision, gastroplasty, and anterior G.E.	Good.
	83	Non-malignant hour-glass with large ulcer	Polya	Good.
	100	Non-malignant hour-glass	Polya	Died (collapse).
	16x	Non-malignant hour-glass	Polya	Died (pneumonia).
	17x	Non-malignant hour-glass	Polya	Died (acute dilatation).
	42x	Non-malignant hour-glass	G.E.	Good.
	45x	Non-malignant hour-glass	Polya	Good.

G.E.=gastro-enterostomy.

In gastric ulcer, as in duodenal and gastro-jejunal ulcer, Morton's experiments have brought us appreciably nearer to an accurate understanding of the etiology, but have not brought us quite to the central point of the problem. He has for the first time succeeded in transforming an acute gastric lesion into a typically chronic ulcer. Again, the method employed is duodenal drainage, and again the clinician is left with the question as to what in the clinical case of gastric ulcer corresponds to duodenal drainage in the experiment; and what is it in the clinical case which corresponds to the experimental acute gastric lesion which duodenal drainage transforms into the typical chronic ulcer?

In speaking in Manchester on the subject of gastric ulcer I cannot refrain from allusion to the discussion in which Manchester bore so important a part. In spite of the findings of the Manchester Committee and of the modified form in which Charles Mayo recently stated the doctrine of the origin of cancer in benign ulcer, I see from the Mayo staff proceedings in January, 1928, that McCarty reiterates his conviction that nearly all ulcers of a diameter of 2.5 cm. and over are malignant, and that in 12 per cent. of apparently benign ulcers a cytoplasia of cancerous nature—not to be recognized in sections stained by ordinary means, but recognizable by special histological methods—is present. The only aspect of the question on which I can from my own cases express any opinion is the clinical one.

In none of the ulcers on which I have operated by simple gastro-entrostomy have we found anything in the "follow-up" to suggest the subsequent development of cancer. Further, as will be seen from the tables, all large ulcers and many of the smaller have been excised—sometimes by themselves, at other times as part of the stomach removed in partial gastrectomy. I have not kept all measurements, but in a good proportion of the cases the ulcer was the size of a five-shilling piece or half-crown (see Fig. 7), without any

FIG. 7.—Drawing from x-ray photograph in Case No. 157. An example of a large-sized non-malignant ulcer of the posterior wall, eroding pancreas, and transverse mesocolon.

histological evidence of malignancy and without subsequent recurrence. On the other hand, all malignant ulcers which I have encountered have been of the size of a five-shilling piece and upwards.

In no case of ulcer, large or small, has cancer subsequently developed where the histological findings on the specimen removed at operation were non-malignant.

The immediate mortality in the various groups is almost entirely due to pulmonary complications. To what extent are these pulmonary complications the result of the anaesthetic? The matter has been debated many

times. Personally I think the anaesthetic is usually responsible. I have not had an opportunity of using ethylene, which American surgeons find such a help. The danger of pushing anaesthesia to the point of complete relaxation, and the consequent difficulty in closing an incompletely relaxed abdomen, have been held responsible for many of the ventral hernias in the upper abdomen. Inasmuch as this complication is common to all abdominal operations I have not included cases of post-operative hernia as unsatisfactory results in the figures above given.

In the choice of a site for the abdominal incision which will avoid ventral hernia surgical opinion is swinging back to the mid-line, where the interlacing fibres give a secure grip to the sutures. Personally I like to reinforce the continuous catgut in the essential layer with "figure of 8" silk-worm-gut sutures held taut on a frame. Since adopting this method I have so far had no ventral hernia in any gastric or duodenal case, although many times the condition of the patient did not warrant pushing the anaesthetic to complete relaxation, and in some cases, especially in perforation, the wound did not heal without some suppuration.

## TUMOURS OF THE FRONTAL LOBE OF THE BRAIN.

BY

J. PURDON MARTIN, M.A., M.D., M.R.C.P.,  
ASSISTANT PHYSICIAN TO THE NATIONAL HOSPITAL FOR NERVOUS  
DISEASES, QUEEN SQUARE; PHYSICIAN TO THE SEAMEN'S AND  
BOLINGBROKE HOSPITALS.

Tumours of the frontal lobes of the brain anterior to the pre-central gyrus are notoriously difficult to diagnose. The following three cases in which the necropsies were performed within a period of less than three months seem to be worth recording because they form a group in which there was considerable similarity, and they indicate the chief lines of a general clinical picture.

### CASE I.

An engineer, admitted to the National Hospital, Queen Square, had felt perfectly well up till March, 1926; one morning in that month, after walking a few yards from his house, he ran back, mounted the stairs two at a time, stooped to pick up a book, and fell unconscious. When his wife reached the room a few moments later he was still unconscious, was foaming at the mouth, and had bitten his tongue; his face and jaw were twitching, but not his limbs, and there was no incontinence. It is said that the attack lasted ten to fifteen minutes; the patient did not then recover consciousness, but appeared to pass into a sleep, from which he could not be roused. After several hours of sleep he had another fit, described as "most violent," in which he "struggled" with all his limbs. After a few hours' more sleep he recovered consciousness and complained of severe headache, but nothing abnormal was noticed about him; his mental condition was that of a patient who had had a severe illness, and he was content to commit himself unreservedly to the care of others. Subjectively the patient recovered considerably in a few days, but his mental state of docility

persisted more or less. He returned to his work and seems to have performed it normally for three months; at the end of that period he had another fit. This, like the former, was a generalized seizure with unconsciousness; after this he did not return to work. For the next six months he was free from gross symptoms, but there was some slight mental deterioration; he lost his initiative, relied increasingly on his wife, and became so forgetful and absent-minded that he could not be trusted to go out alone. He does not seem to have been troubled with headaches during this period. On Christmas Day, 1926, he had a severe headache; this persisted throughout the next day and led up to another fit in the afternoon of December 27th. My first examination was made about ten days after this third seizure. The patient then had had continuous headache, not, however, of any great intensity, since the occurrence of the last fit.

This examination in January, except for a certain abnormal mental state and two objective signs to be mentioned later, revealed nothing abnormal. No defect could be discovered in the motor or sensory functions; in particular, the optic discs were normal, as also were the visual acuity and the visual fields. The sense of smell was intact in both nostrils, and odours could be distinguished and named. The cerebro-spinal fluid showed no cells and no excess of protein; the Wassermann reaction was negative both in the fluid and blood. An x-ray examination of the skull gave no indication of any bony change. The two slight signs referred to were an occasional fine tremor of the hands, such as is commonly seen in nervous patients at a first examination, and an exaggerated flexor response in the plantar reflexes. The patient remained in hospital for four weeks, and during that time had frequent headaches, but after the lumbar puncture the headache ceased for several days. After investigation he was allowed to go home (he said that he "felt quite well"), and was instructed to report himself if any new symptoms developed. Bromide and luminal were given during this time. After two months the patient returned to the outpatient department, complaining of a loss of vision and the occurrence of "petit mal" attacks—momentary losses of consciousness about three times a week. It was found a week later that the visual acuity of the left eye had diminished to 6/60 and that of the right to 6/9. The left disc showed some doubtful pallor of its temporal half and the right appeared normal; colours of small objects could not be distinguished in any part of the field of the left eye.

The patient was again admitted to hospital under my care on April 9th, 1927. At that time, more than a year after his first fit, his condition was as follows. He answered questions and behaved intelligently, and had no delusions or hallucinations, but he did not seem to realize fully the seriousness of the threatened blindness. He was probably somewhat deficient emotionally, and was slightly euphoric; there was less than the usual emotional modulation in his voice. His speech was tremulous and slow, but there was no aphasia; his memory was bad. The sense of smell was still normal on both sides. The vision was seriously impaired. In the right eye there was a central scotoma, which was quickly enlarging, though the disc appeared normal. In the left eye acuity was reduced to counting fingers at half a metre, and the central and upper temporal parts of the field were completely obliterated; on the disc there was some temporal pallor. The pupil reactions and eye movements were normal. The right palpebral fissure was wider than the left, suggesting slight weakness of the right facial muscles, but such weakness as there was did not affect voluntary movements. The remaining cranial nerve functions were normal. In the limbs no motor or sensory abnormality was found except that the patient was at times generally tremulous. This was a fine irregular tremor, not unlike that seen in early stages of general paralysis, and it affected his speech as well as his limbs. All the abdominal reflexes were brisk. The plantar reflexes were peculiar in that they were very briskly flexor: the slightest touch of the sole produced full and immediate flexion of the great toe, unaccompanied by any withdrawal of the foot. The gait was normal and there was no incontinence.

During May the vision rapidly deteriorated and the temporal parts of both discs became pale; the visual field of the right eye was almost entirely obliterated by enlargement of the central scotoma. An x-ray photograph of the skull now showed some change about the pituitary fossa, and rather open sutures suggesting intracranial pressure. It seemed that there must be a tumour involving the optic chiasma and the optic nerves, affecting the left side more than the right; it was decided to explore that region by operation. On June 22nd the operation was performed by Mr. Sargent, the exploration being made through a quadrilateral opening in the left frontal bone. Part of the temporal bone in the temporal fossa was extremely thin; the dura was very tense, and to relieve the tension about 40 c.c.m. of cerebro-spinal fluid were withdrawn by lumbar puncture. When the dura had been opened and the left frontal lobe was elevated a soft gelatinous-looking mass was seen protruding from under the frontal lobe, on the outer side of the olfactory bulb. It surrounded the left optic nerve and the chiasma, and from these structures a portion of it was dissected off; the site of origin of this growth could not be determined. This operation resulted in a considerable improvement in the patient's vision, and the wound healed uneventfully.

A few weeks later definite weakness of the right side of the face and right arm began to develop, and was accompanied by motor aphasia. At this stage (July 29th, 1927) the plantar reflexes were still of the same exaggerated flexor type as before, and stroking of the sole of the left foot caused flexion of the great toe on the right side as well as on the left; but by Oppenheim's method a feeble extensor response could be obtained on the left. During the last few weeks of his life the patient was emotional and very depressed. His general state gradually deteriorated, and he died on August 28th, 1927.

At the necropsy a very hard tumour was found on the medial

surface of the left frontal lobe; it reached the inferior surface of the lobe in the region of the olfactory tract and passed thence forwards to, but did not involve, the optic chiasma. The anterior clinoid processes were completely eroded; so that there was a hollow in front of the pituitary body. When the brain was cut, after hardening, the left frontal lobe was found to be filled with a firm whitish tumour-mass, which shaded off imperceptibly into the white matter of the brain; it involved the head of the caudate nucleus, and, medial to that, formed a rounded boss on the internal aspect of the lateral ventricle. It did not extend higher than the genu of the corpus callosum. Microscopically it was formed of a dense neuroglial network with rather scanty small nuclei (astrocytoma fibrillare).

#### Summary.

Onset of the symptoms with a severe convulsive attack; slight but increasing mental changes of the nature of a loss of initiative, loss of memory, increasing reliance on others, insufficient realization of his condition, euphoria; tremor of the hands and in the voice, not constant and not noticed when the patient was in bed; headaches; further convulsions and frequent "petit mal" attacks; a year after the onset rapid diminution of vision and partial atrophy of the optic nerves; flexor plantar responses of exaggerated briskness.

The necropsy confirmed the presence of a tumour in the left frontal lobe. A noteworthy negative feature was the absence until the last stages of the illness of practically all abnormal motor phenomena except tremor; there were no symptoms in the olfactory system, no speech symptoms, and no ataxia.

#### CASE II.

An electrician, aged 34, seen by me at the London Temperance Hospital, had been employed in Greece, where it was his duty to instruct and supervise native workers. Seven months before his admission to hospital he had begun to make stupid mistakes and had become useless as a supervisor; he was forgetful, and was dismissed by the firm for "slackness." Three or four months before admission he began to suffer from headaches; he referred the pain chiefly to the right mastoid region, where he had had an injury some years previously. He had never had a fit. There was no history of vomiting. At times he was excessively drowsy.

In giving his history he made mistakes in dates and in periods of time. When I examined him on October 11th, 1927, he did not know the date, and had not even an approximate idea of the length of time he had been in hospital. He was slightly euphoric. He seemed to have little understanding of discipline, and broke the rules of the hospital in regard to smoking, but evidently without any malice or appreciation of wrong-doing, or even of the fact that he was doing anything unusual. He was, in fact, very submissive when addressed. Sometimes during examination he would do something other than he was asked, apparently because he failed to form a correct idea of the action which was required of him (ideational apraxia). Repeatedly when asked to show his teeth he put out his tongue, and he did not realize his mistake. He answered questions intelligently, and could read and describe what he had read, and could write.

There was no loss of smell. The optic discs may have been a little blurred in the upper nasal quadrants, but were not definitely pathological; the visual fields responded normally to finger tests, and the pupils and eye movements were normal. There was a slight "smoothness" or emotional weakness of the left side of the face at rest, but no weakness was seen in voluntary movement. The remaining cranial nerve functions were normal. In the arms power, sensation, tendon-jerks, pointing tests, and the control of fine movements were all normal; there was no persisting hand-grasp. While the patient was lying down there was usually no tremor of the hands, but when he sat up there were frequent short attacks of gross irregular tremor like that of general paralysis, more marked, if anything, in the left hand than in the right. All the abdominal reflexes were brisk. In the lower limbs power, sensation, and tendon-jerks were normal. The plantar reflexes were both briskly-flexor in an extreme degree; the merest touch of the sole causing full and immediate flexion, without any withdrawal of the foot such as occurs when the sole is very sensitive; with persistent stimulation the flexor response on the left side seemed to tire, and gave place to a slight extensor reflex, with some withdrawal at the knee. When the patient stood up he tended to fall backwards, and when walking he was inclined to deviate to the right. He had incontinence (of the mental type) of both urine and faeces. The cerebro-spinal fluid was normal in its cellular and albumin content, and the Wassermann reaction was negative both in this fluid and in the blood. There was a slight irregular rise of temperature, and the pulse rate was consistently about 60 per minute. The opinion was expressed that the cause of the symptoms was a tumour, or possibly chronic abscesses, involving both frontal lobes, but chiefly the right.

On October 20th the patient had a convulsion, and after several hours of unconsciousness he died. The necropsy was performed at the hospital by Dr. Sanguinetti. In the horizontal section of the brain, passing through the genu of the corpus callosum, there was a tumour on the right side as large as a pigeon's egg, just anterior to and touching the caudate nucleus. It lay right in the path of the fibres of the "forceps minor" radiating out into the front lobe from the corpus callosum, and at this level it was well demarcated, but it extended downwards and forwards into the lobe, and there its boundary was less definite. On the left side there was a mass of tumour, probably of later development, occupying the medial part of the frontal lobe just anterior to the corpus callosum; its outline was much less definite than that of the tumour on the right side. Microscopically the growth was a polymorphocellular sarcoma.

#### Summary.

Gradual development of mental symptoms—loss of mental "sharpness," stupid mistakes, inability to supervise others, loss of memory, later intentional apraxia; headaches; tremor of the hands like that in general paralysis of the insane; tendency to fall backwards when standing and to deviate to the right when walking; excessively brisk flexor plantar responses; slight left facial weakness at rest and slight extensor plantar response on the left side with persistent stimulation.

The presence of a bilateral frontal lobe tumour was verified after death. The absence of definite optic disc changes and of vomiting, of olfactory symptoms, aphasia, and all kinds of paralysis should be noted.

#### CASE III.

An unmarried woman, aged 58, a boxmaker, came to the out-patients' department at the National Hospital, Queen Square, on November 1st, 1927; she was said to have suffered from depression for about a year, but until July 15th she was otherwise well. On that day she had a fit, without warning, in the street. After this she was "not quite herself," though she returned to her work and seems to have carried it on normally. During this period it was observed that she often rubbed her nose as if it itched. She remained at work until September 18th, when she was more depressed than usual, and during the afternoon she fell down in a fit. This was the first of a series of fits which lasted till 11 o'clock the next morning, and the patient was more or less unconscious for forty-eight hours. Early in the attack she was removed to a hospital; when she recovered consciousness she had no paralysis or aphasia, and she left the hospital after a stay of five days. She was able to dress herself and walk to the car which took her home. After her return her manner was strange; she was "absent-minded" and confused, her memory was bad, and she could not be trusted to do ordinary things, such as to dress herself, because she would make mistakes; she had to be directed constantly and was very docile. About a month later she began to "worry about things which she ought to have known were perfectly all right." She had frequent headaches and sometimes complained of pain over the right eye.

When I addressed a question to her at the out-patient department she did not answer, but turned to her companion as though to shift the onus of answering on to her. But when an answer was required of herself she stated her name, age, address, and some of her complaints correctly. Only in answer to one question regarding the duration of a symptom did she say, "I don't remember." Her speech was somewhat slow and monotonous, but there was no aphasia. Physical examination revealed no abnormalities in the cranial nerve functions or any changes in power or sensation in the limbs. The tendon-jerks were brisk, the right plantar reflex flexor, and the left doubtfully extensor. There was a general rhythmical tremor of the hands, and the patient volunteered the statement, which was confirmed by observation, that the tremor was more pronounced in the left hand than in the right; the difference was, however, variable. All the abdominal reflexes were weak. The provisional diagnosis was "frontal tumour, right or bilateral."

She was admitted to hospital under my care two days later. Her general condition quickly became worse; she was very drowsy, tended to become comatose, and was incontinent of urine and faeces. The cerebro-spinal fluid was under high pressure (300 mm. aq.); it contained a very large number of cells (270 per mm.), of which nearly all were polymorphonuclears, and it had a very high protein content (0.130 per cent.). This cerebro-spinal fluid analysis suggested the presence of an abscess, but several other features of the case were opposed to that view. However, in case an abscess might be present, and in the hope of relieving the patient's general condition by cerebral decompression, it was decided to operate. On November 8th Mr. Armour exposed the right frontal lobe by a fronto-temporal craniectomy; in the posterior portion of the second frontal convolution there was a small brownish tumour, about half an inch in diameter, slightly raised above the surface of the neighbouring convolutions, and this was removed. After the operation the patient remained in a very drowsy and feeble state for three days and then died.

At the necropsy, when the brain had been hardened, section revealed no other mass in the right frontal lobe, but in the left frontal lobe there were several masses similar to that which had been removed from the right; these masses extended almost to the tip of the lobe and across the genu of the corpus callosum. The whole of the left frontal lobe was much larger than its fellow. Microscopic section of the mass removed at operation showed that it was a glioma. The masses in the left lobe had a similar structure, and the remainder of the left frontal lobe was filled with gliomatous tissue unusually rich in fibres. Such tissue would probably interfere little with the functions of the nerve cells of the part.

#### Summary.

A woman, aged 58, suffered from unusual mental depression for several months and then had a convulsive attack; after an interval of two months a very severe series of convulsions occurred. Mental changes then became apparent—confusion, loss of memory, liability to make mistakes in everyday duties, abnormal reliance on others; headaches became frequent; tremor of the hands was observed. Towards the end the plantar responses had become not flexor, but indefinite.

After death a tumour was found involving both frontal lobes. The absence of signs and symptoms in the olfactory and visual systems and the absence of aphasia and of paralysis of every kind are noteworthy.

The difficulty in the diagnosis of frontal tumours lies in the paucity of the reliable physical signs and symptoms. Headache, vomiting, and papilloedema are still regarded as the cardinal signs of an established cerebral tumour, but in frontal lobe cases vomiting and papilloedema do not usually develop, and frontal tumours must be diagnosed in their absence. The absence of all recognizable paralysis and of aphasia has been noted in the foregoing cases. Only when the tumour lies towards the posterior part of the frontal lobe are such signs to be expected, the growth then being sufficiently near to the pre-central convolution, or to Broca's area or the insula, to interfere with the function of these parts by actual destruction or by oedema.

Generalized headache such as occurred in all three cases must be the result of increased intracranial pressure; it is therefore unlikely to occur until the growth is large enough to give rise to some dislocation of the brain and consequent impediment to the outflow of cerebro-spinal fluid from the ventricles. In none of these cases was the general headache intense until other symptoms had been established. In Case III pain over the left eye was one of the patient's most frequent complaints; such local pains are probably due to a local stretching of the dura or to erosion of bone.

Convulsions were an early symptom in two out of the three cases, and were the first definite indication of disease. They occurred at a time when nothing abnormal was to be made out, except perhaps some vague mental change. They were generalized attacks, associated with prolonged headache, and sometimes with continued unconsciousness. Attacks of such severity and of such absolute suddenness are rarely caused by tumours in other parts of the brain. In one case typical "petit mal" attacks also occurred.

The mental alterations met with in frontal tumour cases are not specific for tumours of this localization; similar changes are common in cases of tumours in other parts of the brain if there has been prolonged intracranial hypertension; but when they are encountered in the absence of papilloedema these mental changes certainly have a localizing value. The most constant psychical modification—one which was met with in all these cases—is an abnormal submissiveness or docility, and a child-like reliance on others; with this goes a loss of initiative. Some loss of memory is frequent, and confusion may occur: the patient may become liable to make mistakes and omissions in everyday actions, and in this way act indecently. The incontinence which occurred towards the end in two of these cases is to be regarded as a symptom of dementia and not as the result of any paralysis. The first patient of this group was somewhat euphoric; none of them showed that tendency to make a joke at every remark (Witzelsucht) which is probably more indicative of a frontal lobe lesion than any other single mental symptom. These mental changes occur with frontal tumours of either side of the brain.

Tremor was the only observed clinical sign except the mental changes which was common to all three of these cases. In the first patient it was a slight general tremulousness, which at first attracted little attention, but it was more pronounced when the patient was seen in the outpatient department than when he was at rest in the ward. I cannot say now whether it was greater on one side than on the other. In the second patient the tremor was most pronounced, and in his case it was a coarse tremor occurring in frequent short attacks each lasting a minute or so. These attacks seemed to be more likely to come on when he was sitting up or standing than when he was lying down; they usually affected both hands, but on one occasion, while in bed, he had a paroxysm of trembling affecting the left side only. The third patient's tremor, like that of the first, was a fine tremor, but it was more regular. It was more easily perceptible by palpation than by sight, and might easily have been overlooked; moreover, it was bilateral. A tremor affecting the side of the body on which the tumour was situated was described in frontal lobe tumour cases by Dr. Grainger Stewart, and it is generally accepted that the tremor of these cases is homolateral. In two of my cases the tremor was bilateral, the tumour being bilateral also, but even in the third case, in which the tumour was confined to the left side, the tremor affected both sides in some degree. So far as I am aware

there is no reason for referring this tremor to destruction of any particular part of the frontal lobes.

Reflex changes in all these cases were few. The tendon jerks were within normal limits; the abdominal reflexes were present in all, and in the first two were brisk. The plantar reflexes were indefinite in one case, but in the other two cases they were peculiarly exaggerated. The slightest touch to the sole of the foot caused full and immediate flexion of the great toe; the patients showed no signs of unusual sensitiveness of the sole of the foot and made no voluntary withdrawal or other movement. In both cases the phenomenon was bilateral, and in the first case, in which the tumour was on the left side, stimulation of the sole of the right foot caused brisk flexion of the great toe, not only on the right foot, but also on the left movement on the left side occurring a little later than that on the right. Stimulation of the left sole caused flexion of the left toe only. The exaggerated plantar response was one of the earliest abnormal signs in Case I, being present at the time of my first examination of the patient, when no other abnormal physical signs were to be found. I have met this same phenomenon in two other cases in which there were meningeal tumours affecting the frontal lobes by pressure, but I am unable to say whether it is confined to cases of frontal lobe lesion. It is worth of notice that while this phenomenon was actually present an extensor response could be obtained in Case I by Oppenheim's method, and in Case II after persistent stimulation of the sole, the flexor response seeming to tire. The observation of the "crossed flexor response" in Case I was made by Dr. Ferguson, house-physician at the Nation Hospital. This peculiar sign could be obtained constant from the time when it was first noticed up till the patient's death a month later; it is evidently a further development of the exaggerated flexor response, and its occurrence is evidence that the exaggerated flexor response is definitely a pathological sign.

Of the signs which may arise in the olfactory and visual systems little need be said. A unilateral anosmia is of more precise value than almost any other sign of frontal tumour, but unfortunately it rarely occurs early, and, in the first case described, it was entirely absent until other signs had put the diagnosis beyond doubt. Optic interference, if unilateral, is also very valuable, but bilateral visual defect such as occurred in the first of these cases has so many more common causes that it is likely to mislead.

The ataxia encountered in the second case is a well known sign in frontal tumours, but in my experience only met with at an advanced stage of the disease, and both for this reason and on account of the difficulty of distinguishing it from the ataxia of a cerebellar lesion, it is of little practical value for diagnosis.

#### *Differential Diagnosis.*

Even when one is faced with definite clinical signs the diagnosis of these cases has to be made from general paralysis of the insane, cerebral syphilis, cerebral vascular disease, disseminated sclerosis, Schilder's disease, and other forms of gliosis, and also from tumours of the temporal lobe. The Wassermann reaction, the age of the patient, and the general state of the circulatory system may rule out the first three of these. Disseminated sclerosis is likely to cause more reflex changes than frontal tumour, while the other diffuse diseases are likely to be eliminated by the age of the patient or the rate of progress of the malady. The occurrence of severe generalized headaches is a point in favour of a neoplasm, and the cerebro-spinal fluid pressures measured at lumbar puncture may give more precise evidence of its presence. Temporal lobe tumours usually bring about an homonymous visual field defect, they cause papilloedema relatively early, and they do not give rise to tremor. In the presence of merely the earlier signs of frontal tumour the most difficult point may be to determine on which side the tumour lies. The mental changes do not help to decide this, but the preponderance of tremor on one side indicates that the tumour is on the same side; any visual, olfactory, speech, or motor signs are likely to settle the point. The great tendency of frontal lobe tumours to become bilateral must be borne in mind.

## Summary.

Three cases of frontal lobe tumour are described, in two of which the growths were bilateral.

The only observed clinical signs which were common to all three cases were mental changes and tremor.

In two cases severe generalized convulsive attacks constituted the first definite symptom.

Attention is drawn to a peculiar exaggeration of the plantar reflexes encountered in two of the cases.

## TUMOUR OF THE BRAIN SIMULATING ENCEPHALITIS LETHARGICA.

BY

S. McCLEMENTS, M.R.C.S., L.R.C.P.

THE rarity of a cerebral tumour giving rise to the clinical picture of encephalitis lethargica in its early and penultimate stages is so marked that the following case deserves attention.

A man, aged 57, had a mild attack of influenza in April, 1926, and was reported as completely well in the third week of the following month. Four weeks later an insidious onset of drowsiness and lethargy began, and was followed in a few days by dimness of vision for near objects. The drowsiness gradually deepened for four weeks, and the patient complained of double vision; the temperature during the same period oscillated between 98° and 100° F. The period of stupor reached its height at the end of July, and was followed by marked improvement in the patient's condition, as shown by his taking an increasing interest in his surroundings and in the disappearance of diplopia. Except for spasmodic twitching of his legs he had almost regained his normal health in September. In October and December, 1926, and April, 1927, he had relapses which were followed with marked improvement, although it was noticed that each successive improvement left the patient a little more stuporous. In June, 1927, he became markedly lethargic, and on July 13th he was admitted to hospital for treatment, his condition having been definitely diagnosed by a neurologist as encephalitis lethargica. On admission his temperature was 98° F., and his pulse 74. He continued in a stuporous condition, but when awakened his mental condition appeared quite clear and he was able to answer questions in a rational manner. The face was smoothed out and expressionless, the eyelids were in a condition of ptosis, his voice was monotonous, but not indistinct, his right eye showed an internal strabismus, and on being questioned he said he saw two fingers instead of one which I held before him. There was dimness of vision for near objects, the pupillary reflex to light was absent on the right side and sluggish on the left; reaction to accommodation was normal. The tendon, abdominal, and plantar reflexes remained unaffected.

Although signs of improvement were occasionally manifested the stupor gradually deepened, and the vision of the right eye diminished so rapidly that a more detailed ophthalmological examination was made. The ocular reflexes had not altered since the previous examination; there was paresis of the external rectus on the right side, associated with well-marked papilloedema of the right optic disc, and the retinal veins of the left fundus appeared slightly swollen. These findings pointed to the probability of a neoplasm localized to the right frontal region of the brain, producing pressure on the right second and sixth cranial nerves and causing the papilloedema.

A cerebral gumma being suspected as the cause of the mischief a Wassermann test of the blood was performed; the reaction was positive. Antisyphilitic treatment, in the form of potassium iodide and liquor hydrarg. perchlor. internally, and neosalvarsan intramuscularly, was started at once, but there was no response, and the patient died on November 30th, 1927, eight weeks after the commencement of the treatment.

The autopsy revealed a spherical tumour, two inches in diameter and gelatinous in consistency, lying in a smooth walled cavity of the right frontal lobe of the cerebrum; posteriorly between the tumour and the wall of the cavity was a clot of blood an inch long and a quarter of an inch broad.

The points of interest in the case are:

1. The earlier symptoms—namely, gradually progressing drowsiness, dimness of vision, diplopia, ptosis of eyelids, and occasional slight rises of temperature—were identical with the clinical manifestations in a large group of cases of encephalitis lethargica.

2. Complete absence of headache and vomiting, which are almost invariably present in the later stages of cerebral tumour.

3. The importance of ophthalmoscopic examination of the eyes in every case pointing to a lesion of the central nervous system.

It is very much regretted that there was no histological examination of the tumour; perhaps an expert in neuropathology would venture an opinion as to the nature of the neoplasm.

## ISOLATION OF *B. TYPHOSUS* FROM SEWAGE AND SHELLFISH.

BY

W. JAMES WILSON, M.D., D.Sc.,

PROFESSOR OF HYGIENE AND PUBLIC HEALTH, QUEEN'S UNIVERSITY,  
BELFAST; WATER EXAMINER TO BELFAST WATER BOARD.

THE danger of consumption of sewage-contaminated water, shellfish, watercress, etc., is a cardinal article of the hygienist's faith, but hitherto it has not been possible to find objective evidence by the cultivation of the typhoid bacillus from the sewage. By the use of a new technique I can now demonstrate on an average the presence of one typhoid bacillus in each cubic centimetre of Belfast sewage.

Sir Alexander Houston<sup>1</sup> in 1913 and 1914 examined 23,353 non-lactose fermenting colonies developing on plates inoculated mainly with samples of London (Barking) or Hendon sewage, and also with individual samples from Dublin, Belfast, Edinburgh, and Aberdeen. He was unsuccessful in isolating a single *B. typhosus*, and concluded that the typhoid bacillus is not uniformly present in 0.00066 c.cm. of crude sewage, and that this amount of sewage contains 704 excretal bacteria per cubic centimetre. Dealing with the difficulties of the task Houston writes:

"Sewage contains such an enormous number of bacteria that it is quite impracticable to examine more than a very small amount of this material. For example, to examine one cubic centimetre of crude sewage for typhoid bacilli by the direct plating method would mean making at least 1,000 special plate cultures and at least 20,000 primary subcultures, not to speak of the secondary and other cultures for the purpose of differentiation. It is, however, quite practicable to work with as much as 0.01 c.cm. of sewage spread over from 10 to 20 special plates, and therefore to make 200 to 400 primary cultures."

Non-lactose fermenting organisms are so common in sewage that many thousands or hundreds of thousands of such colonies would require to be examined in order to isolate a single typhoid bacillus. For example, in Belfast sewage I find that on an average 400,000 to 500,000 organisms develop from 1 c.cm. on MacConkey lactose bile salt agar plates, and that of these more than one-half are non-lactose fermenters. In such sewage I have found about one typhoid bacillus in each cubic centimetre, so that, using the MacConkey medium, there would have been a chance of isolating the bacillus if 250,000 non-lactose fermenting colonies had been tested. In all probability, even after such a Herculean effort, failure would have resulted, as the chances are that the typhoid bacillus would not have had a clear space on the plate to develop, and its growth would have been obscured and inhibited by the coliform colonies. The addition of brilliant green to the medium would doubtless render the isolation of *B. typhosus* from sewage not quite so difficult, but even so the chances against a non-lactose fermenting colony being composed of typhoid bacilli would be many thousands to one. In the examination of sewage for the presence of *B. typhosus* I therefore made use of the glucose-sulphite-iron-bismuth-brilliant green medium of Wilson and Blair,<sup>2</sup> the efficiency of which depends on two original observations of mine: (1) *B. typhosus* in the presence of a fermentable carbohydrate is able to reduce a sulphite to a sulphide, and so to form a black colony in the presence of an iron salt. (2) Bismuth sulphite in the presence of a certain excess of sodium sulphite suppresses the growth of most coliform bacilli; in the presence of brilliant green the selective action is intensified. This medium has in my hands rendered the isolation of *B. typhosus* from enteric stools one of the easiest procedures in applied bacteriology, and recently by means of it B. A. Adams<sup>3</sup> has isolated the same bacillus from the excreta of seagulls.

When 0.5 to 1 c.cm. of sewage is poured over the surface of a plate of the medium and allowed to dry, and is then incubated for twenty-four hours at 37° C., black colonies with a metallic halo are developed, and also light green colonies of *B. proteus*. It is among the black colonies that *B. typhosus* is to be sought. All the black colonies, if subcultured on MacConkey or Endo medium, will be found to consist of non-lactose fermenters, so that these media are not very helpful in distinguishing between colonies of *B. typhosus* and those of other reducing bacteria. It was found that a very large proportion of the black

colonies simulating those of *B. typhosus* were saccharose fermenters, so that the use of saccharose in a modified Endo medium enabled me to distinguish rapidly between them and those of *B. typhosus*. The principal organism forming these black colonies on the bismuth sulphite medium is present in most specimens of sewage, but has not so far been found by me in faeces. The chief characters of this organism, to which I have given the name of *B. effluviai*, are as follows: A Gram-negative actively motile bacillus with growth on agar resembling *B. coli*; in liquefying gelatin and in being negative to methyl red and giving a positive reaction to the Voges-Proskauer test, it resembles *B. cloacae*, from which it differs in its reduction of sulphites and in being a non-lactose fermenter. It grows in Koser's citrate solution. It ferments glucose, maltose, mannite, saccharose, and starch, with the production of acid and gas, and has no action on lactose, dulcitol, and salicin. It forms indol and digests inspissated serum.

The *B. effluviai* is probably related to the *B. proteus* group, although it ferments mannite and does not decompose urea.

### Material Employed.

Crude fresh-screened sewage was taken from the combined sewage of the upper and lower level sewers of Belfast on its way to the sedimentation tanks. On three occasions the samples were taken at 10 a.m., on the fourth at 2 p.m. The sewage was flowing along and was taken up in a sterile bottle, and may be regarded as representative of the ordinary dry weather sewage of Belfast. One sample taken on February 25th, 1928, gave the following figures on chemical analysis:

	Parts per 100,000.
Free and saline ammonia	1.4
Albuminoid ammonia	0.8
Oxygen absorbed, two hours, at 80° F.	4.0
Chlorine	25.0

On bacteriological examination it showed 480,000 colonies per cubic centimetre on a MacConkey plate, and of these 218,000 were lactose fermenters and 262,000 non-lactose fermenters. It also contained 200 spores of *B. welchii* per cubic centimetre.

The chief details in connexion with the isolation of the typhoid bacillus may be summarized as follows:

TABLE I.

Sewage.	Date.	Amount of sewage Planted Out.	No. of Black Colonies Examined	No. of Saccharose Fermenters.	No. of Non-saccharose Fermenters.	No. of Typhoid Colonies Found.
Belfast	1928, Feb. 16	4 c.cm.	31	27	4	4
Belfast	Feb. 25	11 c.cm.	67	60	7	2
Belfast	Mar. 8	10 c.cm.	64	50	14	7
Belfast	Mar. 12	5 c.cm.	71	56	15	8

The examination of 30 c.cm. of sewage resulted in the isolation of twenty-one strains of *B. typhosus*. The bacilli were not uniformly distributed in the sewage, some of the plates, yielding none and others several. Probably more bacilli were present than were isolated, and I am of opinion that at least one typhoid bacillus is present in each cubic centimetre of the ordinary, crude screened sewage of Belfast.

Whether the sewage of other cities and towns would yield similar results requires investigation. I may state that Belfast, although at present comparatively free from typhoid fever, was at one time one of the most typhoid-infested cities of Europe, and consequently would be expected to have many typhoid "carriers." From the annual report of the superintendent medical officer of health for Belfast for 1926 I may take the following figures.

Year.	Population.	Deaths from typhoid fever.	Annual enteric mortality rate per 10,000.
1897	310,000	354	11.4
1898	340,000	640	18.8
1901	350,862	341	9.7
1905	360,000	128	3.0
1911	386,449	15	0.4
1920	413,000	34	0.8
1926	416,000	6	0.1

During 1926 there were 84 cases of enteric fever notified in Belfast. It would seem, therefore, that in a town that has been exposed to onthbreaks of typhoid fever the ordinary sewage contains the typhoid bacillus, and that the sanitary policy which aimed at the formation of a clean environment—pure water, pure soil, and the rapid removal of excretal matter from premises—was sound. In such a town our results show that the specific infective agent is liable to be present in ordinary sewage. Nearly all the cases of typhoid fever notified are treated in an isolation hospital, the sewage of which, before discharge into the city sewers, is sterilized by steam; of the 84 patients with enteric fever in Belfast in 1926, 82 were treated in hospital. The source of the bacilli in the sewage is therefore probably mainly "carriers." While the bacilli remain in the sewage as such there is little danger of infection, but there is the possibility of the return of the typhoid bacillus to man again by contamination of the soil, by leaking drains and sewers, by contaminated water supplies, and by the consumption of shellfish living on sewage-polluted shores.

### Shellfish.

The facts relating to the isolation of *B. typhosus* from shellfish collected from Belfast Lough foreshore at Green-castle are as follows. On March 6th seven cockles were opened; the liquor was collected on a sterile Petri dish and was then transferred to nine plates of the special bismuth medium. Nine black colonies were studied, seven being saccharose fermenters and two non-saccharose fermenters; of the latter one proved to be *B. typhosus*.

The bacilli which I regard as being typhoid bacilli were actively motile and Gram-negative; they formed acid but no gas in glucose, maltose, and mannite agar shake cultures. No fermentation of lactose, saccharose, dulcitol, and salicin occurred; indol was not formed, and gelatin was not liquefied.

The bacilli were agglutinated to full titre by four different antityphoid serums, and were not agglutinated by normal serums in dilutions of 1 in 20. That the organisms were typhoid bacilli was established by means of absorption tests. It was found that those recovered from the sewage and the cockles removed from several antityphoid serums the agglutinins acting on them and on genuine typhoid bacilli.

## A CASE OF PROGRESSIVE MUSCULAR ATROPHY OF THE PERONEAL TYPE;

TWENTY-ONE OF THE PATIENT'S RELATIVES BEING ALSO AFFECTED.

BY

GEORGE PARKER, M.A., M.D.,

CONSULTING PHYSICIAN, BRISTOL GENERAL HOSPITAL.

This syndrome was recognized as a distinct type, first by Charcot and Marie in 1886, and independently by Sir Howard Tooth in a thesis the same year. Several cases which were perhaps similar had been recorded previously, such as Osler's Star family in New York, and Meryon's patient in 1852. Herringham, in 1887, published an account of a family where eighteen members were all affected, Symonds brought forward one where nine suffered. Collier one with eight, while Beevor, Bryant, Ormerod, and Schultz have each reported families with three cases.

The disease is transmitted both in the male and in the female line; and there is not the great preponderance of males affected that we get in pseudo-hypertrophic paralysis. As Williams has remarked, however, there are instances where no relatives are affected, and others where several brothers and sisters develop the disease simultaneously for the first time in a family. It has several times appeared after a febrile disease, such as measles. It may commence in childhood, more often in the second or third decade. Generally the first wasting is seen in the feet or peronei on both sides, but occasionally it shows itself first in the hands

and forearms. The wasting and weakness extend very gradually to the upper segments of the limbs, and the muscles of the trunk and face are rarely affected even after thirty or forty years. Bulbar symptoms are unknown. It is important to notice that the reaction of degeneration can be found in some of the muscles in practically every case, while there may or may not be cramps, pains, coldness and lividity of the skin, fibrillary tremors, or slight sensory changes.

My patient, F. J., aged 33, married, with one child, is a strong and otherwise healthy man, in whom the condition first appeared when he was 19 years old. He was then an active footballer and member of a rowing club. He even now plays golf and finds no fatigue from a five-mile walk, though the disease has progressed steadily. The feet were first affected and then the hands and forearms followed. There is no history of any previous illness, and he has rarely required medical treatment. The great age which many of his relatives attained, even when affected like himself, is striking. His heart, kidneys, and lungs are normal, the expansion of his chest is 3 inches. The muscles of the trunk, face, eyes, throat, and tongue are unaffected. He can whistle and point the lips. The action of the bladder and bowels is normal. There is extreme wasting of the muscles of the feet and lower part of the legs, and intrinsic muscles of the hands, and the forearms, and slightly of the thighs. There is no movement at all in the toes or at the ankles; neither abduction nor adduction or flexion of the feet. The great toe and the others are flexed and quite motionless; the arch of the foot is preserved, and his gait in walking is surprisingly good, though slightly high-stepping. He flexes and extends the leg on the thigh and the thigh on the hip freely, but in getting up from the ground he likes a little assistance, such as putting his hand on his thigh, but he can bend down to touch the ground and rise up again easily.

Though the small muscles of the hands are so wasted, the grip is strong, and he has no difficulty in buttoning his clothes or in writing. Supination and pronation have escaped, but extension at the wrist is weak, and the hands when at rest take the claw form. There is little or no fibrillation or muscular irritability on percussion. There is no ataxy. He stands easily with his eyes shut, and the pupils react to light. The knee-jerks are present, but weak; the Achilles tendon-jerk is present, but there is no plantar reflex or clonus. He has no pain or cramps, and the sensation to light touch or pin-prick appears normal over hands, feet, and trunk. There is no reaction to either current in feet, calves, or hands, but some of the extensors at the wrists show reaction of degeneration—that is, no faradic reaction but good galvanic, with the positive pole equal to or greater than the negative.

In this patient, then, we get wasting of the distal segments of the limbs with loss of power, beginning in early adult life and steadily progressing. The reflexes are diminished and reaction of degeneration is present. Finally, it appears from his statements that eleven males and ten females of his family are similarly affected. In this family the first case recorded is that of the patient's great-grandfather, and out of fifty-four of his descendants twenty-one are already affected and others are not yet old enough. The disease seems to pass rather more readily by the male line than the female, and it has little effect on the duration of life. In a group of five brothers and sisters affected, two are alive aged 77 and 79, and three died at ages of 62, 82, and 86.

One would like to know whether the affection did actually begin with the great-grandfather. It cannot have existed many generations back at the present rate of increase, for the district would be full of cases; whereas the disease is always a rare one.

The type is clearly distinct from the myopathies. Thus—  
(1) Pseudo-hypertrophic paralysis has neither the distal distribution of wasting nor the reaction of degeneration, and it generally shows some muscles enlarged.

(2) The rare cases of distal myopathy, such as the one recorded by Gowers, appear to have the facial muscles involved and no reaction of degeneration.

(3) The Werdnig-Hoffmann type is really myelopathy, but the wasting begins in the proximal segments during the second and third years of life, and death usually follows in three or four years. Reaction of degeneration is found in these cases, and several may occur in one family.

(4) In amyotonia the trouble begins at birth or soon after. There is no definite wasting, but paresis of the distal segments which may improve if the patient survives. I think there is no affection of other members of the family here, but reaction of degeneration may be present.

My group of symptoms, then, differs widely from all these. The pathology of this peroneal type does not seem to have been made much clearer of late. The sclerosis in the columns of Goll and Burdach, and the lesions in the

anterior horn cells and in the peripheral nerves, appear to vary in intensity in different cases, but we are completely ignorant of the cause which produces them. Whether it be "a developmental weakness, an inherited susceptibility to some toxin," or a true infection, spirochaetal or otherwise, remains to be proved.

## PARALYSIS OF ALL FOUR LIMBS CURED BY REMOVAL OF A SPINAL TUMOUR.

BY

WALTER BROADBENT, M.D. CANTAB., F.R.C.P.,

SENIOR PHYSICIAN,

AND

G. W. BERESFORD, O.B.E., F.R.C.S.,

ASSISTANT SURGEON, ROYAL SUSSEX COUNTY HOSPITAL.

A woman, aged 51, was admitted to hospital in October with complete paralysis of the right arm and leg and partial paralysis of the left arm and leg. She also complained of intense headache and gnawing and shooting pains in both arms; these were so severe that hypodermic morphine was needed to give her any sleep.

The history given was that fourteen months previously she had first noticed numbness in the right hand, but this did not bother her until in February she tripped over something and had a bad fall, which shook her considerably. After that she began to lose the use of her right arm. By May the arm was so weak that she had to give up her work, and she was beginning to drag the right foot. There was also then some aching pain in the shoulders and right arm. Early in July the right hand had become useless, and the trouble in the right leg had advanced so much that she could not walk, also the left leg was affected. By the end of August the right arm and leg were paralysed, and she could only move the left leg slightly, and there was weakness in the left shoulder.

On admission the right arm and leg were motionless; she could draw up the left leg slightly as she lay in bed. She could not abduct the left shoulder, but could adduct and rotate it, and flex the forearm. The grasp of the hand was very weak, and she could not feed herself with it. Both the trapezii were wasted, but not the arm muscles. Reflexes were increased.

She complained of intense headache and agonizing shooting and aching pains in both shoulders, and of "pins and needles" all over the body. The pain had been getting worse and worse for the past six weeks. There was anaesthesia of the right hand and forearm, and diminished sensation in the same area on the left arm. Sensation over the legs and body was less than normal, and distinction between heat and cold was not accurate. There was no incontinence, but it was difficult to get the bowels to act.

The neck could be rotated and flexed, and an x-ray photograph showed no disease of the bones. On lumbar puncture the cerebro-spinal fluid was not under pressure. It contained globulin in large excess, colloidal gold 55544,33221, Fehling reduced normally, no increase of cells. The Wassermann reaction was negative. The cerebro-spinal fluid of the cisterno puncture contained only a very faint trace of globulin, colloidal gold 01110,00000, no cells. It would be interesting to know if this striking difference in the cerebro-spinal fluid below and above the tumour occurs in other cases.

The diagnosis made was a lesion of the spinal cord about the level of the second cervical vertebra, and, on account of the intense pain, probably a tumour in the meninges pressing on the back of the cord. Mr. Beresford was asked to do a cisterno puncture and insert some lipiodol. X-ray photographs after this showed some lipiodol just above the level of the first cervical, and opposite the level of the first and second cervical vertebrae.

After the operation the movements of the left arm soon began to improve, next those of the left leg. It was nearly a month before the right leg showed signs of recovery, and the right arm later still. Massage and

faradism were used to hasten the return of movement. After ten weeks the patient could walk with a little assistance, spasticity not having quite disappeared. Movements of the left arm and hand were perfect, and she could lift a glass to her mouth with the right hand.

The operation described by Mr. Beresford:

On November 8th, 1927, under intratracheal anaesthesia (Dr. Eccles), the laminae of the second, third, fourth, and fifth cervical vertebrae were removed. The dura was not pulsating and felt hard in the second, third, and fourth cervical region. On opening the dura a tumour was seen in the postero-lateral aspect pressing into the right side of the cord. The tumour, which was attached by a pedicle to the dura, was enucleated without difficulty. Its appearance was rather like a large raspberry, fleshy to feel, and not very vascular. It measured 2.75 by 1.5 by 1 centimetres.

The dura was closed with continuous catgut, and, after closing the wound, the head, neck, and shoulders were supported in a plaster cast. The patient left the theatre in good condition, and got immediate relief from her intense headache. Sections of the tumour show it to be an endothelioma. This tumour is said to be non-malignant, and therefore the prognosis in this case is good.

## COMPLETE TRANSVERSE RUPTURE OF THE JEJUNUM WITHOUT EXTERNAL WOUND.

BY

J. R. ARMSTRONG, M.R.C.S., L.R.C.P.,

LATE RESIDENT MEDICAL OFFICER, NELSON HOSPITAL, MERTON, S.W.

COMPLETE transverse rupture of the intestine is rare in the absence of external wounds. Moreover, recovery from such a condition is exceptional. The following details of a case of such rupture of the jejunum seem worthy of record, particularly in view of the satisfactory issue.

A man, aged 46, was brought to the Nelson Hospital on July 20th, 1927, suffering from severe abdominal injury. The history given was that while riding a motor bicycle he had lost control and crashed into a wall, his abdomen striking a projecting corner.

On arrival at hospital the patient was in great pain and suffering from severe shock. He was in a cold sweat, and complained of intense pain in the abdomen, which at times caused him to writhe in agony. The pulse was 64, and the temperature 97.5° F. Breathing was laboured with grunting expiration and almost entirely thoracic; vomiting did not occur. The pupils were equal and contracted, and reacted to light and accommodation. The whole of the anterior abdominal wall was intensely rigid and motionless, while the only external sign of injury was a slight discoloration or contusion just below the ribs in the left hypochondrium. On palpation the abdomen was extremely tender everywhere, and a point of maximum tenderness could be elicited in the region of the tip of the spleen. There was definite dullness in the flanks, especially on the left side, but the patient was so ill that shifting dullness was not investigated. Liver dullness was present. The bladder was not distended; a catheter was passed and normal urine withdrawn. A diagnosis of grave abdominal injury with rupture of a viscus, possibly the spleen, was made, and the patient was treated for shock, 1/2 c.cm. of pituitrin being given together with a rectal saline injection, morphine, and atropine.

Two hours later Dr. Martin Randall opened the abdomen; a large left paramedian incision was used, with the centre opposite the umbilicus. No gas escaped on opening the peritoneum, and no fluid or odour suggestive of rupture of a hollow viscus was perceptible. There was a large quantity of almost pure blood in the peritoneal cavity. Examination of the liver, spleen, stomach, and pancreas revealed no injury, but while the last-named was being investigated a loose torn end of bowel came into view. This proved to be the jejunum, about four inches beyond the duodeno-jejunal flexure. The other end was found without difficulty, the tear separating the two pieces of bowel extending a full inch into the mesentery. The edges of the severed bowel were somewhat irregular, but it was practically a clean transverse tear. The removal of about half an inch on each side sufficed to form a clean-cut edge for suture, and an end-to-end anastomosis was performed. The peritoneum having been sponged quickly, the incision was closed, but a drainage tube was placed in the left loin and another in the pelvis, since some fluid was still present in each of these situations. After the operation the temperature was 97.4° F., and the pulse 88. The patient was given 1/4 grain of morphine at midnight, and saline by the rectum and subcutaneously.

At 6 a.m. the next day he was given a further 1/6 grain of morphine, and throughout the day continuous rectal saline. The temperature rose to 99° F., and the pulse to 116. Throughout the day the patient was given an ounce of water at a time, and during the day 1 drachm of brandy. In the evening he was given

an enema, and he passed a considerable quantity of flatus, with a slight action of the bowels. At night he was given 1/6 grain of morphine and at 4 a.m. on the next day a further 1/12 grain. During the day he seemed to have improved, the temperature being 98.6° F., and the pulse 104; vomiting occurred four times, and in the evening the stomach was washed out with sodium bicarbonate, which arrested this. From this time onwards the patient continued to progress satisfactorily; distension was relieved by turpentine enemata. The temperature remained normal or slightly subnormal, and the pulse rate had fallen to 70 by July 24th. The patient suffered from some distressing hiccup, which, however, responded to a simple mixture of bismuth, and he continued to progress until he was discharged from hospital on August 27th, 1927, in good health.

A series of cases recorded by Massie<sup>1</sup> at Guy's Hospital between the years 1899 and 1922 shows that rupture of the intestine occurred in 34 instances. Of these, 26 were situated in the small intestine, and the jejunum was more commonly injured than the ileum; of the 14 jejunal cases, 7 occurred within eighteen inches of the duodeno-jejunal flexure. It was also shown that the part most susceptible to injury is that part which crosses the vertebral column, and that the second and third loops of the gut are most frequently involved. Most of these lesions were partial, and nearly all cases where the duodenum was involved were associated with other severe injuries in the upper abdominal wall. This writer also points out that, whereas cases of ruptured stomach and duodenum are accompanied by other injuries, generally intra-abdominal, cases of rupture of the small intestine are usually single, and are not associated with any other injury. This fact is borne out by the present case.

The main symptoms and signs are pain, shock, and rigidity. It has been said that impairment of liver dullness is to be expected, but in the series collected by Massie this occurred in only 3 out of 34 cases; in the present case there was no impairment. Of 31 cases reported of complete ruptured small intestine the mortality was found to be 78 per cent., and in 9 cases in which the rupture was complete the mortality was 87 per cent. The high mortality in cases of complete rupture is said to be due to the increased amount of shock as compared with cases of partial rupture.

Another series of cases, numbering 22, and occurring at the London Hospital between the years 1913 and 1922, is recorded by Huddy.<sup>2</sup> This writer emphasizes the importance of early operation, the significance of pain as an indication for operation, and the fallibility of relying on the pulse rate—that is, not operating because it is slow. Again, such signs as loss of liver dullness, surgical emphysema, and distension are not of great clinical value; the latter is generally a late result, and is often found with other injuries, such as damaged kidneys or fractured pelvis; emphasis is also laid on the fact that the mortality increases with the length of the history, and that operation should not be delayed if there is no improvement after three hours. In the present case diagnosis of grave internal injury was easy on account of the extreme rigidity, great shock, and the definite evidence of effusion into the peritoneum.

The decision to operate depends on the diagnosis of grave internal damage and not on a diagnosis of any exact form of injury, and the earliest moment at which the condition of the patient is such as to make it possible should be the time chosen for operation.

The points that seem to be of special interest in this case are the following. On opening the abdomen no gas was detected, nor was there any fluid or smell suggestive of a rupture of a hollow viscus. The only fluid that escaped was blood, possibly diluted by peritoneal serous exudate. Nothing resembling food could be found in the effusion, and the inevitable presumption is that the intestine was empty when injured; the shock was followed by a pyloric spasm, which persisted until the operation was performed, because the stomach was not empty, the patient having had ten a short time before the accident occurred. The success of the operation was probably largely due to its being undertaken early.

I am indebted to Dr. Randall for assistance in describing this case and for permission to publish it.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### CONGENITAL ABSENCE OF ONE OVARY AND THE CORRESPONDING FALLOPIAN TUBE.

On November 20th, 1926 (p. 938) I published a case of complete atresia of the oesophagus. More recently the mother of this infant required operative treatment and the developmental abnormality thus revealed seems worthy of recording.

The patient, aged 23, was sent to me with pelvic trouble. In the course of a vaginal examination nothing abnormal was felt on the right side, but marked tenderness and a swelling were noticeable on the left side; after some local treatment surgical intervention appeared necessary. Dr. Arthur Woo performed the operation and I assisted him, Dr. Milward giving the anaesthetic.

On opening the abdomen we found the left tube much inflamed, but no pus could be expressed from it. While seeking for the right tube a most interesting condition was found; the fundus of the uterus was quite free on the right side and there was total absence of the tube and ovary. A long appendix reached across towards the left tube, and since it showed signs of an inflammatory condition it was removed. The patient made an uneventful recovery. There were no signs of any previous operation, and the history of the patient, whom I had known for many years, made me quite certain that this was a case of congenital absence of ovary and tube in a woman from whom I had delivered both male and female children.

The patient was born in London in 1901; she was brought to Hong-Kong when she was 7 months old, and remained here without going away until after her marriage in October, 1922. She went to England in 1923, and while there her periods ceased for four to five months; she was examined and it was found that the cause was not pregnancy. She returned to Hong-Kong in November, 1923, and became pregnant; she was delivered of a healthy female child in August, 1924. In December, 1925, she was delivered of the apparently healthy male infant who was, however, found to have no oesophagus. In May, 1926, the patient went to England, and seven months later was delivered there of a healthy female infant. She became pregnant again in September, 1927, but had a miscarriage two months later, which she attributed to hard domestic work.

She returned to Hong-Kong in January, 1928, not at all well, and was admitted to hospital in February for the abdominal operation previously described.

I consider this case most interesting, as we have such an undoubted history of a woman with one ovary bearing both male and female children. There is also the point that a woman with an abnormal condition gave birth to a child with a serious developmental deficiency.

Medical Superintendent, Matilda Hospital, Hong-Kong.

#### AN UNUSUAL TYPE OF VICARIOUS MENSTRUATION.

CASES of vicarious menstruation are fairly common, and are met with so frequently as to occasion very little comment. The haemorrhage usually comes from the mucous membrane of the nose or nasopharynx and more rarely from the nipples. The following case appears rare enough, however, to warrant publication.

The patient, a young woman aged 26, is one of an unhealthy family, several of the members of which have died from pulmonary tuberculosis. About a year ago she developed unmistakable signs of the same disease. She refused sanatorium treatment and her condition became progressively worse. Six months ago I was sent for urgently, being told that she was coughing up considerable quantities of blood. For some weeks previous to this there had been slight haemoptysis, but only to the extent of there being occasional blood-stained sputum.

On arriving at the patient's house I was shown a vessel containing about five ounces of bright red blood, which the patient stated she had suddenly and unexpectedly coughed up. In the course of my examination she mentioned that she was menstruating, but I did not at that time associate the haemoptysis with that circumstance. I was, I remember, pleasantly surprised by the apparent success of the measures I took to stop what seemed to be a serious haemorrhage, for on the next day there was only a little blood mixed with the sputum and after two more days this had stopped. At this time there was a well-marked cavity in the upper lobe of the right lung and areas of consolidation elsewhere in both lungs. Expectoration was free and copious.

At each subsequent menstrual period there has been the same train of events. On the first day there is a severe haemoptysis

followed by two or three days of blood-stained sputum, and by the time the menstrual flow has ceased the sputum has, except on two occasions, been free from blood. I have noticed as the menstrual period approaches that the amount of sputum increases and there is, so to say, a general moistening of the lung spaces. Between the periods the cough is hard and rather dry.

Since the severe haemoptysis has occurred only at the onset of menstruation, and the last seven menstrual periods have had haemoptysis as an accompaniment, I think I am justified in labelling the condition vicarious menstruation, though of an uncommon variety.

I ought to add, perhaps, that until this state of affairs began, the girl had normal menstruation, unaccompanied by any unusual circumstances.

Portladow, Ireland.

R. S. CHAPMAN, M.B., B.Ch.

#### A CASE OF EAR PRESENTATION.

THE following details of a case of ear presentation appear to be of sufficient interest to merit placing on record.

A 2-para, aged 27, was admitted to hospital at 6 a.m. on April 25th; labour had commenced in the early morning, and the membranes had ruptured at 4 o'clock. On admission a second vertex presentation was diagnosed. The measurements of the pelvis were: interspinous 8 in. and the intercrural 9½ in. The external conjugate was 7½ in. There was full dilatation of the cervix at 7.15 a.m., but no advance in labour. The patient was in good condition, the pains occurring every three minutes. On examination a foetal ear could be seen at the vulva, while on vaginal examination the head was found to be lying in the transverse diameter, the occiput to the right, and the head flexed laterally on the neck.

I tried manual rotation, at first without success, but later, under a general anaesthetic, by pushing the head up into the vagina, I managed to rotate it into an occipito-anterior presentation. Forceps were then applied, and a live child was delivered.

The child had a large caput succedaneum on the left side of the face, extending on to the ear, and there was slight facial paralysis. It weighed 5 lb. 5 oz., and had the following measurements: Suboccipito-bregmatic 3½ in., bitemporal 3 in., suboccipito-frontal 3½ in., biparietal 3½ in., circumference 13 in.

The caput and the paralysis disappeared in four days. The mother had an uninterrupted puerperium, and was discharged on May 6th.

The case is of interest as a marked example of Naegeli's obliquity which had not corrected itself. It is interesting to note that in 1921 the mother was admitted as an emergency case. The condition then was a persistent occipito-posterior presentation with prolapse of the cord. In 1923 she had a normal delivery.

I am indebted to Mr. Louis Carnac Rivett for his permission to publish the case.

Queen Mary's Hospital, Stratford, E.

## Reports of Societies.

#### THE TREATMENT OF ECLAMPSIA.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on June 15th, with Mr. COMYNS BERKELEY in the chair, a paper by Professor W. STROGANOFF of Leningrad, an honorary member of the Society, was read in his absence by the honorary secretary, Dr. W. GILLIATT, who also anglicized what was described as the author's Anglo-Russian. During Professor Stroganoff's visit to this country in 1924 he read a paper to the Section (*British Medical Journal*, July 12th, p. 53) in which he described his method for controlling the fits in eclampsia. The cardinal principle in his treatment is that the fits can and must be controlled. All sources of irritation must be removed, an injection of morphine be given immediately, followed an hour later by chloral hydrate, and the administration of chloral hydrate repeated at intervals if delivery is delayed. The technique includes also the application of hot-water bottles, the giving of fluids to stimulate kidney action, the careful cleansing of the mouth, and the administration of oxygen for asphyxia.

The paper read to the Section on June 15th was almost entirely occupied with statistics. Professor Stroganoff

pointed out that eclampsia was still one of the greatest dangers of the child-bearing woman. In the United States the number of maternal deaths annually from eclampsia was 5,000, and from puerperal infection 6,000, so that in view of the greater loss of child life with eclampsia the total mortality was greater than from infection. In England and Wales albuminuria and eclampsia had first place among complications of child-bearing. In Germany there had been lately an improvement in the general mortality rate from eclampsia, though many clinics still gave very poor results. The figures from every country showed the need for investigation with a view to reducing maternal morbidity and mortality and for strict attention to every detail in the management of pregnancy and labour. In one German clinic where the prophylactic method had been adopted, out of 48 cases of eclampsia there had been only three deaths, and two of these women were moribund when admitted to the clinic. In Japan at one clinic after the adoption of the prophylactic method the death rate in eclampsia had fallen from 34 per cent. to 20 per cent. Professor Stroganoff was of opinion that the prophylactic treatment properly applied in eclampsia, in cases which had been neither neglected nor infected, should prevent a mortality higher than between 1 and 2 per cent., and if neglected and infected cases were included the mortality should not be higher than from 2.5 to 4 per cent. The trouble was that so far none of the followers of his method had treated a sufficient number of cases, say 300 or so, to permit of a more sure judgement. A few workers also had had bad results with the prophylactic method, the reason being, in his opinion, that the treatment was not employed correctly. Many appeared to think that a fixed scheme of administration of narcotics was the essential difference between the old and the new methods, whereas in fact his treatment provided for a variation from the fixed scheme of administration, such variation depending on the condition of the patient. Where the results of the treatment had proved unfortunate he had usually found a lack of variety in the procedure.

Professor Stroganoff went on to describe in detail many of his cases and groups of cases, with the nature of the delivery and the after-history. In his own clinic, of 300 patients admitted for eclampsia 8 had died, a mortality of 2.6 per cent., and of the fatal cases 4 were moribund when they reached the hospital, and died from three to eight hours after admission. In only one of the eight fatal cases was it impossible to control the convulsions, and in 40 per cent. of the 300 cases there was not a single fit after the beginning of treatment. A large number of intermittent eclampsias were observed—that is to say, there was freedom from fits for twelve hours or more before delivery. Professor Stroganoff appeared to complain somewhat of the fewness of cases treated, or recorded as treated, by his method in Vienna, Berlin, and London, though in London he acknowledged the work done by Mr. Aleck Bourne. Discussing the question of technique, he said that his observation of over 1,000 cases was that Caesarean section in eclampsia very frequently caused death. He advocated the use of the quartz lamp in the treatment; it involved no danger and gave a useful vasodilatation. Luminal was useful as a substitute for chloral hydrate; it was less dangerous to the heart, but its disadvantage was in its instability. Chloral hydrate was a powerful narcotic, and it was scarcely possible to do without it in severe cases, but after the fits had been controlled for eight or ten hours the substitution of luminal might well be tried. He had less faith in magnesium sulphate, which had been praised by American doctors. In conclusion he pointed again to the persistent high mortality from eclampsia, in spite of some reduction during the last twelve or fifteen years following the adoption of prophylactic treatment. Technically the method was not easy of application, but it was very necessary that it should have a wide and thorough trial.

The CHAIRMAN said that the Section would desire to convey to Professor Stroganoff its congratulations on his results. He appeared to be rather under the impression—a mistaken one—that a large number of obstetricians

in Europe did not think very much of his treatment, and the reason why he had forwarded this paper, which did not contain anything very new, was for purposes of propaganda. There was a reference in the paper to the desirability of telephone consultations; these might be very useful in Russia, where consultants lived at a great distance, but in this country they were perhaps not so necessary.

Major FLEMING Gow, I.M.S., said that he could appreciate Professor Stroganoff's reference to the telephone, for he happened to have lived in a part of Persia which had come under Russian influence, and there, backward as Persia was supposed to be, the telephone was used in quite an extraordinary way. Speaking of his Indian experience, he said that in India very commonly the cases were not seen until after the patient had had eight or ten fits. During the earlier part of the time she was attended often by very low caste women who applied some primitive treatment. A slight decrease in mortality had been obtained in India, but in the nature of the case there were no results comparable with those in Western countries. Even in India there were some variations in treatment and results. In Madras, for example, venesection was extensively practised, in addition to the Stroganoff treatment, but in Bengal there were few cases in which it was advisable to do venesection, because it was very rare for a Bengali woman to have a blood pressure of anything like 160, even in bad cases of eclampsia. He had practically given up doing Caesarean section for eclampsia. The eclamptic cases occurred in primiparae who, in Bengal, were aged about 13 or 14, and the under-development of the pelvis in these girls was such that Caesarean section was not practicable.

Professor LOUISE McILROY was of opinion that Professor Stroganoff had not given this country quite the position it deserved, for in ante-natal work Britain was in the van of nations. With regard to eclampsia the speaker had been informed by medical officers of health that the incidence was steadily going down. There must always be a certain percentage of mortality, from the fulminating case which could not be controlled. Mr. L. C. RIVETT said that at Queen Mary's Hospital for the East End, out of forty-four cases of eclampsia there had been three deaths. He believed that a standard method should be universally adopted.

Dr. W. GILLIATT, in reply to a question relating to a diminished output of chlorides, said that he had at present a patient who was diabetic for many years and became pregnant, twins being delivered. In the pre-insulin era pregnancy with one child would have been enough to have killed her. During her pregnancy, owing presumably to the foetal pancreas, she required less insulin than before. She was admitted to the maternity ward, and it was decided that the delivery offering least risk was by Caesarean section. But, apart from this decision, the procedure was forced upon them because the patient suddenly stopped excreting chlorides, and coincidentally had an oedema which became enormous. She never had a fit or a suggestion of eclampsia, nor did she produce albuminuria. Both she and the infants were doing extremely well, but she was having to take more insulin now than during pregnancy.

A MEETING of the Wolverhampton and District Clinical Club was held at the General Hospital, Wolverhampton, on June 12th, with Dr. W. M. BROWN in the chair. Dr. G. DYAS, in a description of the process of cholecystography, emphasized the advantages of the oral, as opposed to the intravenous, method of administering the drug sodium-tetra-iodo-phenolphthalein. The possibility of severe constitutional disturbance, of local reaction, or thrombosis of the arm, as well as the necessity for the hospitalization of the patient in the intravenous method, were, in his opinion, sufficiently convincing reasons for his personal preference for the oral method. Dr. C. L. SPACKMAN described a case of renal tuberculosis with tubercle bacilli in the urine which had been complicated by several unusual features. Dr. W. M. BROWN illustrated the uses of the ophthalmoscope as a part of the armamentarium of the general practitioner, paying special attention to its value in the recognition of early stages of disease of the central nervous system.

## Reviews.

### THE SIMPLE GOITRES.

In August, 1927, Colonel ROBERT McCARRISON presented a report to the International Conference on Goitre, held at Berne under the auspices of the Swiss Goitre Commission, which he now publishes, in a slightly amplified form and with an introduction of six pages, under the title of *The Simple Goitres*.<sup>1</sup> It is divided into two parts, the text occupying 39 pages and the larger remainder consisting of illustrations, which are most successfully reproduced.

There are, Colonel McCarrison insists, several forms of simple or non-toxic goitre, and also several causes, each as important as the other. Undue importance has been attached to iodine deficiency, which, indeed, has been regarded as the one and only causal factor, and the value of the prophylactic administration of iodine has been exaggerated, whereas its failures have been regarded with a blind eye. While fully admitting that an adequate supply of iodine is essential in preventing a certain type or types of goitre, the author is emphatic that iodine is not a panacea for all types, and that it has not been proved that its deficiency is the ultimate cause of any form of goitre. The known goitre-producing influences include deficiency and excess of food, iodine deficiency, polluted water, gastro-intestinal infection, and insanitary conditions of life. It should be borne in mind that thyroid enlargement, especially in young girls, is physiological, and should not be described as "incipient goitre," as apparently has been done in some goitre surveys.

Three forms of simple goitre are described: (1) the parenchymatous or chronic hypertrophic type, which is endemic in mountainous regions, is explained by a combination of infection and iodine deficiency—this form is considered at much greater length than the other two; (2) the diffuse colloid type of endemic goitre, which, on his own observations, the author tentatively suggests may be due to a disturbance of the calcium iodine balance in the food, and possibly in the gland itself—this is the form endemic in the Great Lakes district in North America; (3) the lymph-adenoid form, described in 1925 by Williamson and Pearce as the hypertrophic reaction of a physiologically insufficient organ with which there occurs a preponderance of lymphocytic aggregates, fibrosis, and a peculiar atrophy of the parenchyma. Experimentally, Colonel McCarrison produced this form in rats fed on a diet deficient in vitamins A, B, and C, and he argues that thus a physiologically subnormal state of the thyroid, and so the production of toxic metabolites—and also a physiologically subnormal state of the gastro-intestinal tract, with stasis and toxic absorption from the blood—result.

During his quarter of a century's work on goitre the character, geographical incidence, and sequelae of goitre have changed, the grosser manifestations, even in endemic areas have become less common, and instead small goitres, more widespread geographically and prone to be associated with thyrotoxicosis, have become more frequent. In describing only three forms of simple goitre the author modestly says that he has but touched the fringe of the subject. It is a book which will well repay thoughtful perusal.

### OPHTHALMIC SURGERY.

A THIRD edition<sup>2</sup> of Professor TERRIEN's textbook of the surgery of the eye and its annexes has appeared. The work has been considerably enlarged, and much of the earlier editions has been rewritten. It is now a massive volume of 646 pages, with no fewer than 565 figures in the text. Most of these illustrations are excellent, well conceived, and well drawn, and they greatly enhance the value of the work. Some of those, however, which are reproductions of photographs are unsatisfactory—that figure which purports to show the bleb of the conjunctiva due to filtration through

the sclerotomy fistula produced by Lagrange's operation for glaucoma is so obscure that it might be anything or nothing.

The description of Lagrange's operation is excellent: it is to the work of that surgeon that we are indebted for the basic idea of modern operations for glaucoma. His was the conception that a permanent filtration scar might be obtained by removing a minute portion of the sclero-corneal margin; the many operations that have been practised are no more than variations in the working out of this idea. Some of them certainly are an improvement on Lagrange's original method, for effective though that was, it entailed a considerable wounding of the eye. The merit of trephining—and most ophthalmic surgeons employ the method of Elliot—is that there is a minimum of wounding to secure a full effect. In the description of trephining there is a figure in which the site of the hole is incorrectly given; it appears there wholly in the sclera, where it would be ineffective.

The chapters on cataract operations are excellently done; so too are the descriptions of the methods of dealing with obstinate after-cataract. There are also good accounts of the several modes of removing cataract in the capsule. It is curious to note that whereas ambidexterity seems the rule for operators in this country, so that the surgeon standing behind his patient's head will incise the cornea upwards with the right hand for the right eye and with the left hand for the left eye, and make each section with equal ease and accuracy, it is otherwise on the Continent, where for the most part the surgeon still adopts the right-handed method for each eye.

Some criticism might be made of the book owing to what appears a lack of balance. A relatively large portion is given to elaborate and detailed accounts of plastic operation on the lids and conjunctiva. As a matter of common experience these operations are not everyday operations, and they do not conform to definite lines of procedure. Nor is the margin between success and failure a hair's breadth as it is in cataract operations; so that there is much less need for detailed descriptions of the plastic operations and much more for ingenuity and resource on the part of the surgeon. The formulation of rigid lines is inclined to cramp his style and diminish the likelihood of successful operation. On page 591 there is an account, with two figures, of the performance of the commonest of all operations connected with the eye—save the removal of foreign bodies—the extirpation of chalazion. We are surprised to find that it is recommended the tumour should be removed through the skin of the lid by an incision parallel to the lid margin. This seems a most undesirable procedure; there will be a skin scar, slight it is true, but slower in healing than a mucous membrane incision. The correct mode of approach, both from anatomical considerations and for rapidity of healing, is through the conjunctiva by an incision parallel with the line of the gland—that is, at right angles to the lid margin. By this method it is possible to remove the chalazion so effectively that bleeding will cease in a few minutes and the patient can go away without a bandage over the eye.

### CLINICAL PATHOLOGY.

WHEN the first edition of Todd's *Clinical Diagnosis by Laboratory Methods* was first published twenty years ago the subject-matter of clinical pathology comprised little more than elementary microscopy, blood counts, and a few simple tests which could be carried out without special training. The development of laboratory investigations during the past two decades, both in the province of biochemistry and of bacteriology, has given to clinical pathology an important place in the medical curriculum. Successive editions of Dr. Todd's textbook have reflected this development of laboratory methods and provided a good working account of useful tests. In the sixth edition<sup>3</sup> Dr. Todd has been assisted by Dr. A. H. SANFORD. No substantial alteration has been made in the arrangement of

<sup>3</sup> *Clinical Diagnosis by Laboratory Methods*. By James Campbell Todd, Ph.B., M.D., and Arthur Huxley Sanford, A.M., M.D. Sixth edition, revised and reset. Philadelphia and London: W. B. Saunders Company, 1927. (Med. 8vo, pp. 743; 345 figures. 28s. net.)

<sup>1</sup> *The Simple Goitres*. By Robert McCarrison, C.I.L., M.D., D.Sc., LL.D., F.R.C.P. London: Baillière, Tindall and Cox, 1928. (Cr. 4to, pp. xi + 10; 143 figures. 10s. 6d. net.)  
<sup>2</sup> *Chirurgie de l'Œil et de ses Annexes*. Par F. Terrien. Troisième édition, augmentée et entièrement refondue. Paris: Masson et Cie, 1927. (Sup. roy. 8vo, pp. viii + 646; 565 figures. 100 fr. sans majoration.)

the book, but a few sections have been rewritten, some tests which further experience has shown to be of little value have been omitted, and others, such as the latest modification of Kahn's flocculation test, have been given a place. The book is of a convenient size, well illustrated, and carefully documented.

All laboratory methods that are useful in the diagnosis and treatment of disease have a right to be grouped under the head of clinical pathology, and in their book<sup>4</sup> with this title Drs. PANTON and MARRACK have given them all a place. Thus they include not only the chemical and microscopic tests, which are part of the regular training of every student, but also sections on bacteriology and morbid histology. Though this may be logical it is of doubtful expediency, for in a book comprising 450 pages, of which only 80 are reserved for bacteriology and about 50 for histology and morbid anatomy, some of the information is bound to be "scrappy." But if the student is willing to learn his bacteriology and histology elsewhere this should prove a useful book to him, particularly because of the descriptions of chemical tests. The illustrations also are good, and have been provided generously.

The chief recommendation for *Clinical Laboratory Procedures*,<sup>5</sup> by Dr. G. L. ROHDEBURG, lies in the fact that the author declares he has used the tests recorded for several years and found them reliable. Since personal experience must always carry weight, it is right that this justification for the present book should be mentioned. For any other justification we have looked in vain. The book is not divided into chapters, has no table of contents, is inadequately indexed, and contains no illustrations. In the majority of cases no judgement is given of the value of the tests mentioned, and the book is nothing but an arid catalogue of how the author does certain things, though why he does them or what he gains from them is not indicated.

The third edition of *Pathological Physiology of Internal Diseases*<sup>6</sup> has been revised and edited by nine of the late Dr. ALBION WALTER HEWLETT's colleagues at Stanford University, California—a task which they undertook as a mark of respect for their former teacher. Dr. Hewlett was a trained physiologist who later in life concentrated his attention on clinical medicine. His book might be called a textbook of functional pathology, for it deals chiefly with changes in function presented by patients suffering from various organic diseases. The two former editions were acknowledged to be valuable contributions to the scientific study of disease. In the third edition the original form and order of presentation have been retained, and the book is brought up to date by the inclusion of recent important advances in clinical physiology.

#### INDUSTRIAL ACCIDENT INSURANCE.

DR. PAUL JOTIKOWITZ has had thirty years' experience of accident practice, and it was appropriate that he should be asked to write a book on the subject to succeed that of Golebiowski, which appeared in the year 1900, and which has become rather out of date owing to the experience acquired in the war and to changes in the accident insurance law in this century. In this *Lehrbuch der Unfall-Heilkunde*<sup>7</sup> these regulations are discussed according to their actual effect in the middle of the year 1926.

The first part deals with the relations between the insurance laws and the practitioner, and defines his duties in carrying out the law. The second part deals with the connexion between diseases and accidents, and the third part treats of injuries and maladies of the several parts of the body and limbs resulting from accident, but

leaves out of consideration the highly specialized subjects of ear and eye diseases and those peculiar to women. This is, however, not a book on treatment, and therefore only in a few instances are questions of treatment discussed, although the probable duration of disability, which often depends on treatment, necessarily occupies an important place. Accordingly the illustrations, of which there are a good many, are intended to help diagnosis, and do not show splints or appliances or methods of wound dressing. As regards wound infection, it is pointed out how important immediate treatment of slight breaches of surface may be, seeing that it is only at first that any attempt at sterilization can succeed. A 10 per cent. iodine solution is recommended for this purpose, as well as the usual precautions against secondary infection. The animal infections, such as anthrax, glanders, and rabies, and all sorts of diseases which may complicate accidents or be incurred in the course of duty, even including aeronaegly, are considered. This last disease, it is thought, may lead, for instance, to flat-foot, which may be complained of as causing incapacity for work. All the usual chemical causes of occupational disease and injuries of muscles, tendons, bones and joints, and blood vessels and nerves, are considered in their general aspects in Part 2. In the descriptions of local injuries and their results in Part 3 the percentage of disability in many cases is stated, and some certain lines of treatment are recommended. This part is very well illustrated; in particular the eighty-one small figures showing almost all the possible mutilations of the hand and fingers, and the percentage disability of each, is likely to be useful, if only for comparison with the scales on which our own Ministry of Pensions allots compensation. A short section on amputations and prostheses, and one on the percentage disabilities of loss of limbs—including toes—concludes the volume.

Awards under the German insurance law are not necessarily guides for deciding cases under our Employers' Liability Acts or the Factory Acts, but it cannot fail to be instructive to compare foreign methods and applications of first principles with our own. This book will enable its readers to do so to a great extent.

#### ANNALS OF MEDICAL HISTORY.

THE first quarterly number of the tenth volume of the *Annals of Medical History*<sup>8</sup> contains ten articles in addition to the editorials and the reviews. The portrait on the cover is that of K. F. Burdach (1776-1847), the story of whose life is related by Dr. T. H. Bast; in the course of his early struggles Burdach in desperation invented a patent pill "eugene," which not unnaturally for a time interfered with his attempts to get a university chair; about six years later, in 1811, he secured a professorship at Dorpat, where he carried out original work, and in 1814, having in the meanwhile declined a chair at St. Petersburg, he moved to Königsberg, where he published his researches on the nervous system and the column which bears his name. The frontispiece represents Dr. Philip Turner (1740-1815), who was an army surgeon for fifty-five years and took part in three wars, eventually becoming surgeon general; Dr. C. B. Graves says that the latter part of his life was one long battle to secure what he believed to be his rightful dues. In his article on "Robert Burns, his medical friends, attendants, and biographer," Dr. H. B. Anderson concludes that the poet's death at the age of 37 was not due to alcoholism, but to rheumatic heart disease, auricular fibrillation, and terminal bacterial endocarditis; the article contains portraits of medical men, including James Currie, who wrote his life. John Wesley, the religious reformer, wrote for the guidance of the poor, in 1747, *Primitive Physick, or an Easy and Natural Method of Curing Most Diseases*, and in his account of this work Dr. Baragar mentions that in the edition of 1780 "quinsy of the breast" is the term used for the angina pectoris described in 1768 by Heberden. Dr. A. H. Barkley shows that Constantine Samuel Rafinesque (1783-1840), who was one of the most brilliant men of his time, and did much to

<sup>4</sup> *Clinical Pathology*. By P. N. Pantou, M.B., B.C. Cantab., and J. R. Marrack, M.D. Cantab. Second edition. London: J. and A. Churchill, 1927. (54 x 9½, pp. viii + 459; 51 figures, 12 plates. 15s.)

<sup>5</sup> *Clinical Laboratory Procedures*. By George L. Rohdenburg, M.D. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1927. (Med. 8vo, pp. 266. 14s. net.)

<sup>6</sup> *Pathological Physiology of Internal Diseases*. By Albion Walter Hewlett, M.D., B.S. Third edition. New York and London: D. Appleton and Co. 1928. (64 x 10, pp. xxxiii + 787. 164 figures. 35s.)

<sup>7</sup> *Lehrbuch der Unfallheilkunde*. Von Dr. Paul Jotikowitz. Lehmanns medizinische Lehrbücher, Band X. München: J. F. Lehmann. 1928. (6½ x 10, pp. xl + 280; 267 figures. M.13.)

<sup>8</sup> *Annals of Medical History* (Spring Number, 1928), vol. x, No. 1. Edited by Francis R. Packard, M.D. New York: Paul B. Hoeber, Inc.; London: Baillière, Tindall and Co. 1928. (8½ x 12½, pp. 110; illustrated. Subscriptions in Great Britain, £2 2s. per volume of four numbers.)

advance intellectual and scientific development in America, was not a doctor, but had an intimate knowledge of the profession, cured himself of pulmonary tuberculosis, and invented a remedy for it called "pulmet." Dr. H. S. Reichle contributes a sketch of Emil Noeggerth (1827-1895), who practised with success for a time in New York, but returned to his native country ten years before his death. In his essay on fees in medical history Dr. H. Dittrick gives examples from Babylon in 2250 B.C. to the recent past. Dr. R. G. Doughty tells the story of the early struggles of the medical department of the University of Georgia, which was started in 1828, and the accomplished editor contributes some excellent book reviews.

#### KALA-AZAR.

In 1918 E. Muir published a small book on the diagnosis and treatment of kala-azar; this reappeared practically as a second edition, much enlarged, under the authorship of E. Muir and L. E. Napier in 1925. The present monograph, *Kala-azar*,<sup>9</sup> by L. EVERARD NAPIER, which now appears, though a lineal descendent of the foregoing volumes, is in fact a completely rewritten book. Dr. Napier is in charge of kala-azar research at the Calcutta School of Tropical Medicine, where he and his colleagues have for the past three years been studying the several problems of this disease, including transmission.

The book deals fully with epidemiology, etiology, pathology, symptomatology, diagnosis with laboratory methods and technique, and treatment. Though *Phlebotomus argentipes* has been incriminated as the vector of kala-azar, actual transmission by its agency has not yet been effected. As the transmission problem is thus unsolved it is discussed at length by the author. The ultimate solution will doubtless not be long delayed, and when this happens it should give us one more example of the value of team work in dealing with such matters. The chapter on treatment will also be read with great interest, as since the introduction of pentavalent compounds of antimony the treatment of kala-azar has been almost revolutionized. With the newer compounds the cure rate is now 95 per cent., the minimum course of treatment has been reduced to a quarter the time formerly necessary, and the relapse rate has been greatly reduced.

#### NOTES ON BOOKS.

It is not surprising that a second edition of Mr. ZACHARY COPE's textbook on *The Treatment of the Acute Abdomen*<sup>10</sup> has been quickly demanded; the first edition was reviewed so recently as February 11th (p. 223). Although the alterations are not extensive they are numerous, and the additions include reference to the investigations of Williams and Brockman on the treatment of the toxæmias of ileus and intestinal obstruction. A fifth edition of *The Early Diagnosis of the Acute Abdomen*,<sup>11</sup> by the same author, has also rapidly followed its predecessor. The symptoms of peritonitis receive more attention, and the symptoms of their etiology and variation are dealt with in a short new section. The symptoms of obstruction of the small intestine has been expanded. Both these books are very valuable, and can be strongly recommended by reason of their practical outlook.

The widespread interest taken in the injection treatment of varicose veins is illustrated by the fact that a third edition of Dr. A. H. DOUTHWAITE's little book<sup>12</sup> has already appeared. An early account of this treatment was contributed by him to our issue of September 25th, 1926 (p. 554), and we noticed at some length the first edition of his book on September 24th, 1927 (p. 558). It remains now to add that the new edition is based on the author's further clinical experience of the method which he advocates.

In the preface to *Operative Dentistry*,<sup>13</sup> which forms the ninth volume of the series *Outlines of Dental Science*, its author, Mr. HAMILTON JAMIESON, tells us that his guiding principle has been to write only of such things as he has personal knowledge of. The ideas, experiences, and personal methods of a colleague he hopes may prove interesting to the busy practitioner and useful to the student. We think he has very well attained his object, and that his little book will be welcomed by members of the dental profession. In short space and in simple wording he has covered the whole ground of "operative dentistry," including the chairside work of denturo construction. From the brevity with which "pyorrhoea" is treated we gather that the author is not greatly impressed with the results of treatment, but we note with interest that "symmetrical extraction for relief of crowding is often extremely beneficial." The suggestion that an excess of over-refined carbohydrate food is responsible for many pyorrhoeas, owing, in part, to its effect in clogging the normal channels of elimination, seems a little difficult to follow; and the idea that a labio-cervical carious cavity may be due to an acid condition of the body generally still more so. We may ask also what evidence the author has of an acid state of the saliva during pregnancy, dyspepsia, or rheumatism such as would cause hypersensitive dentine. As bearing on the vexed question of "root treatment," Mr. Jamieson makes the interesting note that radiolucent areas, not necessarily infected, are observed around the apices of the roots of those teeth the pulps of which have been removed under pressure anaesthesia rather more frequently than in similar cases when arsenic has been used. The author has found "an interesting order of childhood which has been appearing in increasing numbers since the great war." From the illustrations we judge that these children are the subjects of adenoids.

The first edition of *Advice to the Expectant Mother on the Care of Her Health*, by Professor F. J. BROWNE, appeared nearly two years ago, and was noticed in our issue of January 15th, 1927 (p. 106). The second edition,<sup>14</sup> recently published, has been revised and brought up to date. In his preface the author pays a richly deserved tribute to the late Dr. J. W. Ballantyne of Edinburgh, who (as readers of this *Journal* well know) was the first to advocate the necessity of ante-natal care. The paramount importance of this branch of medicine is now so universally recognized by the profession that it is difficult to realize that the first ante-natal bed was endowed as recently as 1902. There is still much need of education along these lines among the laity, and we may confidently expect that Professor Browne's useful pamphlet of forty-eight pages will again justify itself and help to supply this want.

Mr. ERIC PARKER's reminiscent sketches in *Field, River and Hill*<sup>15</sup> are designed, with considerable success, to appeal to those who are fond of the open air and of sport—more particularly fishing and shooting. His book is hardly one to be read at a sitting, consisting as it does partly of articles reprinted from various journals, but it will be valued by those whose professional responsibilities debar them, to their regret, from the delights of the waterside and of the moor, and who will welcome a pleasant "bedside" book dealing with these things. There is a richness of detail in the author's descriptions, based obviously on keen observation, which makes his work something more than mere sporting gossip. He has an eye for nature and for colour, and a knack of characterization which finds an outlet in his good-tempered little studies of men and women. Eight reproductions of drypoint etchings of bird and animal subjects by Miss Winifred Austen add to the attractiveness of the book.

<sup>13</sup> *Operative Dentistry. Outlines of Dental Science*, Vol. IX. By J. D. Hamilton Jamieson, L.D.S.Ed. Edinburgh: E. and S. Livingstone. 1927. (Gr. 8vo, pp. vii + 216; 27 figures. 7s. 6d. net.)

<sup>14</sup> *Advice to the Expectant Mother on the Care of Her Health*. By F. J. Browne, M.D., D.Sc., F.R.C.S.Ed. Second edition. Edinburgh: E. and S. Livingstone. 1928. (Gr. 8vo, pp. 48. 6d. net.)

#### PREPARATIONS AND APPLIANCES.

##### "EUKODAL."

"EUKODAL" (Messrs. Merck, Darmstadt) is a derivative of thebaine, with the chemical name dihydroxy-codeinon hydrochloride. It was discovered by Freund and Speyer in 1917. The drug has been the subject of numerous investigations. Schroder claimed that it was a full substitute for morphine. Other observers found that it was of great value in checking excessive cough, and it was also found to have a powerful analgesic and narcotic action. All observers agree that the toxicity of the drug is low compared with that of morphine, and that the chance of habit formation with eukodal is much less than with morphine. The agents in this country are Messrs. H. R. Napp, Ltd. (3 and 4, Clement's Inn, Kingsway, W.C.2).

<sup>9</sup> *Kala-azar*. By L. Everard Napier, M.R.C.S., L.R.C.P.Lond. Second edition. London, Bombay, and Calcutta: Oxford University Press. 1927. (Gr. 8vo, pp. viii + 203; 18 plates. 8s. 6d. net.)

<sup>10</sup> *The Treatment of the Acute Abdomen*. Second edition. Oxford Medical Publications. London: Milford, Oxford University Press. 1928. (Demy 8vo, pp. xviii + 244; 146 figures. 10s. 6d.)

<sup>12</sup> *The Injection Treatment of Varicose Veins*. By A. H. Douthwaite, M.D., M.R.C.P.Lond. Third Edition. London: H. K. Lewis and Co., Ltd. 1928. (Gr. 8vo, pp. x + 51. 4s. net.)

## Nova et Vetera.

### HARRISON OF IGHTHAM.

#### A VILLAGE ARCHAEOLOGIST.

NESTLING under the North Downs, on a tributary of the Medway, is the village of Ightham, made famous by its grocer—Benjamin Harrison. In the north wall of the parish church is to be found an epitome of his story:

"Benjamin Harrison of Ightham, 1837-1921, the village grocer and archaeologist, whose discoveries of colithic flint implements around Ightham opened up a fruitful field of scientific investigation into the greater antiquity of man. . . . A man of great mind and of kindly disposition."

Many who wish to read the full story of this Kentish man will find it told by his distinguished son, Sir Edward R. Harrison—told with modesty, restraint, but most effectively.<sup>1</sup>

How did it come about that a boy, born in the year 1837, of an ancestry which had stood behind the counter of a small village shop for generations, suddenly broke away from family tradition and devoted himself to solving the problem of man's antiquity? Undoubtedly the factor of heredity came in. His mother, Elizabeth Biggs, came of a stock which possessed inventive ability; the eldest son, Tom, and the youngest, Benjamin, took over from their mother the Biggs's desire for knowledge; the other members of the family were orthodox Harrisons. It was Tom, ten years senior to Benjamin, who led the way. When Benjamin was a boy of 13 he listened to his schoolmaster, Stephen Constable, discuss the geology of the weald with his big brother Tom—for these were days when Lyell's *Elements of Geology* and Chambers's *Vestiges of Creation* were moving all men of an inquiring disposition. The boy took to reading Lyell, Chambers, Gilbert White, *Cassell's Popular Educator*; from the pages of the *Geologist*, taken in by Tom, he learned what geologists of the day were doing. His master, Stephen Constable, led his boys into the weald to trace the gravel drifts which had been laid down by running streams in ancient times. In due time Benjamin went behind the counter to tie packages and snuff candles, while his elder brother Tom sailed for Australia, ultimately entering the Patents Office, Melbourne, where he died in 1897. Without Tom there would have been no Benjamin.

We find this grocer's boy, still in his "teens," constructing relief maps of his native area of Kent out of the various coloured papers then used for sugar wrappings. He developed powers of draughtsmanship, "essential for everyone who takes to concrete science. Before he was 20 he had seen evidence that Ightham had been inhabited during the Romano-British period; he had puzzled over "pits" found in a neighbouring wood, and finding a polished celt or axe there, suspected that the pits were the homes of the men who used such celts—long before the Romans came to England. In due time he and others proved this to be the case. He was grocer's apprentice during the day, but in early mornings and late evenings he was botanist, zoologist, and geologist. Not a ditch was made, a foundation dug, or a gravel pit opened but he was there to see what light they could throw on the archaeological and geological history of his homeland. Especially he desired to know when and how the various deposits of gravels had come to rest where he found them.

In 1863, when he was 25 years of age, he read in the *Geologist* of the palaeolithic implements which Boucher du Perthes had found in the gravels of the Somme valley. Already there had been announcements of the discovery of similar stone implements in the gravels of the Thames valley. Ightham is situated on the watershed between the upper tributaries of the Medway and of the Darent; Harrison inferred that his gravels, especially those along the bottoms of the valleys, should also contain palaeoliths;

he searched for them, found them, and began to form a collection of Kentish palaeoliths. Meantime, his attention had been drawn more and more to Oldbury Hill, to the west of Ightham; he found flint implements there of curious type, which, in the teeth of expert opposition, he finally proved to be the work of late palaeolithic man. Thus at an early point in his career Benjamin Harrison had proved that Romans had lived in Ightham, neolithic man in a neighbouring wood, late palaeolithic man had sheltered under the rocks of Oldbury Hill, and that early palaeolithic man had occupied the neighbouring valley before these had attained their present contours.

Before tracing his career farther let us look at his domestic situation. He married, and took over the business from his father in 1868, being then in his thirty-first year but it can hardly be expected that a village business, however well established, could thrive under a man who wakened early in the morning with geological problems "raining through his head," and who early and late is out searching hill and field and prizing the discovery of a palaeolith above the addition of a new customer. Indeed, he was more intent on making converts of those who came to his shop than on selling them tea and sugar; he was essentially a geological missionary, who desired to educate the working men in his district and to enlist their interest as helpers in his self-imposed task—the long history of Ightham and Ighthamites. His hearing became impaired; in 1877 his first wife died—it had been a happy marriage. Then, in 1879, he married for the second time, and evidently promised to turn over a new leaf of life; at least he dispatched the whole of his collection to the museum in Maidstone, determined to concentrate on business. His old passion proved too strong for him; in less than a year we find him back at his old haunts—but no longer content to search the more recent gravels along the valleys. The palaeolithic implements found there were the work not of apprentices but of skilled hands. To find man's earlier work the old gravels on the ridges which separate the upper water of Medway and Darent had to be searched. He searched them, and found still older and cruder palaeoliths, but even they did not represent the beginning of things. And so it came about, just as he was meditating his second marriage, he began to search in the "gravel-spreads" on the top of the North Downs—infinately older than those of the weald—for man's earliest attempts at making stone tools. Hence, after his second marriage, when the old inquiring Adam in him had once more mastered his business duties, we find him again searching the plateau gravels. In 1881 he believed he had found a rude tool which showed definite evidence of human workmanship; in 1885 he had found others that convinced him of his discovery; by 1887 further discoveries gave him the feeling of certainty. He had come into touch with many of the leading geologists and archaeologists of the time; but without the help of Joseph Prestwich, professor of geology at Oxford, he could never have succeeded in proving his case. Although holding the chair of geology in the University of Oxford Prestwich lived at Shoreham, in the valley of the Darent, eight miles from Ightham. In 1879 he became interested in Harrison's work, and an ideal partnership was established between the two men. Prestwich became adviser, mentor, and critic—for he was Harrison's senior by twenty-five years; he insisted on Harrison supplying complete records of every find and convincing proof of every statement, and in due time was convinced that the plateau gravels of the North Downs did contain rudely chipped stone implements, to which he gave the name "coliths." Harrison was an intensely modest man; publication he regarded as the duty of those who occupied professorial chairs, not of those who stood behind counters. So it came about that Harrison's discoveries were verified and published, with all due credit, at the Geological Society.

logical Institute in 1891. The announcement of Harrison's discovery met with a mixed reception; experts became ranged in a series which extended from the confirmed "die-hards," who rejected coliths of every kind and form as evidence of man's existence, to the extreme optimist, who accepted every chipped stone as the genuine work of human hands. Nor is the dispute now ended; it is true

<sup>1</sup> *Harrison of Ightham*. A book about Benjamin Harrison of Ightham, Kent, made up principally of extracts from his notebooks and correspondence. Prepared for publication by Sir Edward R. Harrison. London: Milford, Oxford University Press, 1928. (Demy 8vo, pp. xi+395; 12 plates. 15s. net.)

that in the last forty years coliths have steadily gained in favour; there has been a gradual movement from the die-hard to the optimist end of the expert scale, but the battle for antiquity is by no means yet decided. Harrison's cause was greatly advanced in 1910, when Mr. Reid Moir first announced the discovery of rostracariate implements under the crag formations of East Anglia. He and Mr. Reid Moir agreed that the Kentish coliths were more primitive in type and older in time than the "suberags" of East Anglia. Both discoveries indicate the existence of Pliocene man in England.

The story of Harrison of Ightham has an interest for

medical men: his type is to be found in every part of England, and it is well that we should recognize and know them, for we can learn much from them. There is, in all their lives, as in that of Benjamin Harrison, an element of tragedy; in 1905, at the age of 68, he "retired from business." In reality business had retired from him, and had it not been for a small pension from the Civil List and an annuity from the Royal Society the tragedy might have been a real one—to everyone except Harrison, for he was one of those happy men who met the buffeting of fate with a smile, and sought only for the welfare of knowledge and of his fellow men.

## THE CAMPAIGN AGAINST LEPROSY.

WHEN it is realized that there are probably about three million lepers in the world, and that about one-third of these are to be found in India alone, it becomes evident that the eradication of this scourge is in great measure a British problem. The annual report for 1927 of the British Empire Leprosy Relief Association indicates in arresting words, statistics, and illustrations what has already been achieved in this respect, and what remains to be done. The most outstanding feature is undoubtedly the fact that cure is now possible if treatment is provided at the commencement of the disease, and the association has therefore addressed itself systematically to the important task of promoting an increasingly intensive search for early cases. Mention is made in the report of the great advance since the discovery of unirritating preparations of sodium hydrocarbate, and of Muir's antimony and potassium iodide treatment. Highly satisfactory progress has been reported, not only in India, but also in South and East Africa; it may be recalled that Mr. Frank Oldrieve, the secretary of the association, visited, in 1927, Uganda, Rhodesia, Kenya, Zanzibar, Tanganyika, and Nyasaland, obtaining a very large amount of valuable information. Among the natives confidence is growing rapidly in the treatment centres, which are financed partly or altogether by the association. An appeal is made for such assistance as will enable this work to be extended still more widely.

Sir Leonard Rogers, who is honorary secretary of the association, commenting on the importance of detecting and treating early cases, emphasizes the value of examining contacts every six months for five years. He believes that in this way a very substantial reduction in the incidence of this disease can be obtained. Dr. Robert Cochrane, who published last year a survey of leprosy in India, to which we referred on August 27th, 1927 (p. 362), has now made a second contribution to what is intended to become a world survey of leprosy. He outlines the present position in various parts of Europe and the Middle and Near East, but devotes considerable attention to Africa, where evidence has been obtained in support of the view that infection usually occurs in childhood. The fact that leprosy is generally a house infection, and that, apart from this, close personal contact is usually necessary for its transmission, brings up the difficult question of segregating infectious cases and of protecting the children of leprosy parents. Compulsory isolation, which proved such an effective measure in Europe in the fourteenth century,

is now usually considered very unsatisfactory, since early cases are thus driven into hiding and the optimum time for treatment is therefore missed. A modern equivalent has been devised in some places in the form of leper centres in pleasant surroundings, where a considerable degree of freedom is allowable. The plan is obviously capable of great extension, since it has been estimated that less than 8 per cent. of the lepers in the British Empire are segregated.

In this connexion we have received an interesting report of the methods adopted in Siam, where there are said to be about 20,000 lepers. In Chiengmai, in the north of Siam, an American physician, Dr. J. W. McKean, is in charge of a leper asylum colony outside the city walls, where in the course of the last twenty years more than 1,000 lepers have been treated. This asylum, of which we

LEPER COLONY, CHIENGMAI, SIAM.

print an illustration, is one of the two large ones in Siam, the other being at Prapadeng. The cost of maintenance of the Chiengmai asylum amounts to nearly £3,000, one-third of which is borne by the Siamese Government and the remainder by voluntary contributions, chiefly received through the American Mission to Lepers. During the earlier years of the work of this institution considerable support was given by British subscribers. In this leper colony the Siamese method of self-government is in operation,

there being a home guard of eighteen persons to preserve order, a sanitary squad of eight, and a welfare committee. Marriage is forbidden, and the men and women live apart, but otherwise there is no compulsion. The colony is open to all races and religions. Each small cottage accommodates two lepers, and is surrounded by a garden; the furnishing of these cottages is very simple in order that strict cleanliness may prevail. Dead lepers are cremated in a building approached by two stairways. A large church with open doors is provided. Such conditions for living compare very advantageously with these in the towns, where large numbers of crippled and disfigured sufferers obtain a scanty livelihood by begging.

We have often referred to the excellent work of the well-known British society the Mission to Lepers, whose journal entitled *Without the Camp* supplies quarterly a record of what is being achieved throughout the world. It may also be mentioned that the May issue of the *The Mission Hospital*, the monthly periodical published by the Church Missionary Society, is devoted to leprosy, and contains an article by Sir Leonard Rogers on recent progress in the campaign against leprosy in the British Empire. With the advance of medical research there appears to be now a real prospect of controlling, and even eradicating, this world scourge, provided only that sufficient financial support is forthcoming.

## THE INDUSTRIAL FATIGUE RESEARCH BOARD.

## REPORT FOR 1927.

It is the practice of the Industrial Fatigue Research Board to publish each year a summary of the work upon which it has been engaged. The investigations, begun, continued, or completed during 1927, form the subject of the eighth annual report, which has just been issued. It is natural that the efforts of so young a handmaid of science should be surrounded with difficulties; that much of the labours of the Board should consist in exploring methods for attacking problems; and that in some cases the solution of a question submitted to the Board has proved unattainable. Thus the Advisory Committee on Women's Occupations asked the Board to inquire into the relation of school-leaving age to well-being and proficiency. After two attempts to define procedure suitable to the subject, the Board, on the advice of its Statistical Committee, was reluctantly compelled to dismiss statistical consideration of the matter, and to confine itself to the investigation of the relation of age to the acquisition of dexterity. In many of the researches it has been found difficult to obtain sufficient comparable material for the study of mass data. During the war many opportunities occurred for collecting such data, over long periods, relating to one specified product. In peace man's demands for products are not limited in the same way. Moreover, analysis of mass data can take no account of the personal and individual peculiarities which are among the most potent influences operative in industry. Consequently, while many of the Board's investigations, such as those dealing with sickness, are still statistical in the sense that the investigator deals with data in the collection of which he plays no part, the procedure now adopted is often the intensive observation of comparatively few individuals. This technique has been applied to the examination of weight-carrying by women, the causation of accidents, and the effect on the individual of repetitive work.

*Menstruation and Working Capacity.*

An inquiry of medical interest has been conducted on the relation of the menstrual cycle to the working capacity of women. The question was explored from two directions. First, Miss S. C. M. Sowton, acting under Dr. C. S. Myers, made daily tests for several months of the muscular and mental efficiency of thirteen university students and sixteen factory operatives, all of whom were kept in ignorance of the purpose of the tests. In the second place, Miss G. M. Bedale, under the direction of Professor E. P. Cathcart, made systematic observations for three months of the basal metabolism, body temperature, and other physiological phenomena in a single subject under strictly controlled conditions. Miss Sowton's investigation showed that the influence of menstruation was no greater than that of other occurrences of an accidental nature; but that individual women differed in their behaviour, some showing a worse performance of the tests about the time of the periods, others a better performance, while in others again no definite difference could be detected. Miss Bedale found that, while there was a heightening of functional activity in the later inter-menstrual period and a fall at menstruation, the fall was no greater than others which often occur accidentally. There was no evidence that a normally healthy woman was rendered physiologically ineffective during menstruation. The Board concludes that, while slight variations in efficiency and functional activity during the menstrual cycle exist in some women, the investigations support the results of an inquiry made in another connexion among welfare workers, from which it appears that very few women are so upset that they have to remain off work even half a day; and that where menstrual trouble occurs at all, the women merely lie down in the rest room for about an hour, and then resume work.

*Accident and Sickness Rates: The Personal Factor.*

The fact that under equal conditions of risk one person is liable to incur more accidents than another has led the Board to the investigation of proficiency in certain sensori-

motor tests. Such proficiency appears to be associated with a relatively low accident rate; and from data obtained from apprentices at the R.A.F. establishment at Halton, and the dockyard at Portsmouth, it is hoped to throw light on the relationship between accident proneness, sickness, and industrial proficiency.

It appears that wide variations exist in the average time lost through sickness in different factories, and that these differences persist consistently. Sickness records are, therefore, being collected from several large firms, and it is hoped that it will be discovered from these, and from examination of the employees, how far psycho-neuroses are associated with a high sickness rate. In such inquiries there is very great difficulty in relating cause and effect; but, as the report points out, though one inquiry may merely suggest a tentative conclusion, repeated suggestions from many inquiries may establish a high degree of probability. Such has been the case in observations on the rate of output on short shifts; on the beneficial influence of short rest pauses; and on the importance of high illumination in fine processes, an inquiry which had the additional advantage of leading to the adoption of specially constructed glasses for the relief of strain on the muscles of accommodation and convergence in workers.

*The Work of the Board.*

The total number of reports issued by the Board has now reached fifty, of which seven were published in 1927 and four in the early part of the present year. It is evident that a vast mass of information is being gathered from experiment and observation, from which the worker of the future should derive much benefit. These efforts should provide an antidote to the callous unconcern for his employee's welfare which is supposed to have characterized the nineteenth century industrialist; to the advantage, it is to be hoped, of the worker's body, without debilitating his moral fibre.

At the end of the present report the Industrial Fatigue Research Board gives an interesting account of the organization used in its investigations. Supervision of the various researches, and strictly scientific criticism of the work generally, have been assigned to four committees: for statistics, for physiology of muscular work, for industrial psychology, for physiology of vision. In the study of involved and complex problems it has been found advisable (without impairing the authority of the four main committees) to assign immediate supervision to special committees of experts with representatives of other Government departments interested. Lastly, in important technical questions, which can only be dealt with satisfactorily by those having a complete knowledge of the industry concerned, the Board has been fortunate in always being able to co-opt on to the appropriate committee, or to add as members of additional temporary committees, representatives of employers or workmen interested in the industry. Eight of these special committees are in existence. The place of Professor E. H. Starling on the Board has been filled by the appointment of Professor E. P. Cathcart, and Dr. C. G. Douglas has taken his place on the committee on physiology of muscular work.

## LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

## ANNUAL GENERAL MEETING.

The annual general meeting of the London and Counties Medical Protection Society was held at Victory House, Leicester Square, London, on June 13th.

Sir JOHN ROSE BRADFORD, president of the society, who was in the chair, said that there had been continued progress during the year. One gratifying feature was the large accession of new members. The society had added to its strength by 1,155, and of this number 706 had applied for membership within a year of their registration. It still remained true, of course, that a very large number of practitioners, to their great risk, did not belong to any defence society. The work of the society had increased in even larger proportion than the membership, partly as the result of the extreme fondness of the public for bringing actions or claims against medical men. These cases

showed that doctors could not be too careful in the precautions they took, especially in their initial relationships with their patients. Scarcely a week passed without the society learning of some proceedings taken or threatened owing to alleged negligence or wrongful act on the part of the doctor.

The annual report of the council was adopted, and Dr. C. M. FEGAN moved the re-election of Sir John Rose Bradford as president; after a tribute to the services which Sir John had rendered to the society, he associated himself with the remarks just made about litigation. The colossal damages originally awarded in the Harnett case had opened the eyes of the man in the street to the possibility of getting cheap money. Were it not for the resolute attitude of the society in fighting any such case where there was a chance of success, litigation would be still more frequent. The resolution, which was seconded by Sir William Hale-White, was carried by general acclamation.

The annual report of the council stated that the membership of the society on December 31st last was 10,872. (The society includes qualified dental practitioners, though not at present those registered as "Dentist, 1921.") The number of applications for advice and assistance during the year was 1,008. In the majority of cases satisfactory results were obtained without litigation, and the results of most of the cases which went on to litigation were also satisfactory. The solicitors' report contained some interesting short summaries of cases dealt with during the year; they state that the general public has become more critical and far more inclined to make complaints and to bring charges against members of the medical and dental professions. This is chiefly attributable, in their opinion, to the national health insurance scheme, the wider education of the public, the effect on the public mind of some spectacular cases in the last few years, and the lurid publicity which has been given to them. The national health insurance scheme, under which complaints may be made against insurance practitioners, has, in the solicitors' opinion, awakened a far more critical and litigious spirit in the general body of the British public, and has provided, with but little risk of expense to the patient, a ready method of finding real or imaginary grievances against individual practitioners.

## LEAD TETRA-ETHYL IN MOTOR SPIRIT.

### COMMITTEE OF INQUIRY.

The committee which, under the chairmanship of Sir Frederick Willis, is inquiring into the use of lead tetra-ethyl in motor spirit held a further meeting on June 11th,\* when Dr. J. P. LEAKE of the United States Public Health Service described the investigation completed in 1926 by a committee appointed under the auspices of the Federal Government; he was himself in charge of the experimental work.

### AMERICAN PUBLIC HEALTH EVIDENCE.

Dr. Leake said that the purpose of the investigation was to determine what dangers, if any, were involved in the manufacture, distribution, and use of lead tetra-ethyl in petrol. It was felt that the results of experiments on animal subjects would not be sufficiently definite, and therefore groups of human subjects were taken. These included two control groups of persons subjected to automobile vapours in garages or in driving, but not lead ethyl petrol, and two similar groups, of 77 and 27 men respectively, working where such petrol was used. There was also a fifth group consisting of men, such as those working on accumulators, who were definitely exposed to certain other lead hazards. The reason for taking this accessory group was to ensure that the methods of inquiry were adequate to show lead absorption when it occurred. Dr. Leake added that there was no foundation for the suggestion of a previous witness that the men using this ethyl petrol were carefully warned beforehand and took special precautions, knowing that the experiment was proceeding; the men, who included some of the earliest workers with this product in the States, were extraordinarily careless, spilling the petrol on their clothes and persons, and, moreover, the garages were in some cases dirty and ill ventilated. The men were subjected to thorough clinical examination. Microscopical examination was made for the stippling of the blood cells, and chemical examination for lead in the faeces. In reply to Sir Frederick Willis, the witness said that he thought, over a large group of men, the test on the excreta furnished a satisfactory index of lead absorption. The examiner at the time of the examination was left unaware as to which of the men had been using the lead product and which were the controls, and

thus any subjective error on his part was as far as possible excluded. In the result this careful clinical examination revealed no cases of lead poisoning except in the fifth group—those definitely exposed to other lead hazards. Among these some cases were found, and their discovery seemed to prove that the tests for toxic action were adequate. The possibility was also borne in mind that employees in the garages where ethyl lead petrol had been used might have suffered from slight symptoms and have left the employment or perhaps the neighbourhood, so that the men remaining were selected individuals who had gained a sort of immunity. A very thorough effort was made to seek out any who had been exposed and had afterwards left the place, but no cases were discovered which gave any ground for the supposition that among ex-workers unnoticed effects might have been forthcoming. Further, owing to the great publicity which had been given to this subject in the States, any deleterious results were even more likely to be reported than diseases ordinarily notifiable.

The conclusion of the American committee was that drivers of cars using ethyl gasoline showed no definite signs of lead absorption after exposures approximating to two years, that employees in ordinary garages might show a certain amount of evidence of lead absorption—possibly due, as the witness afterwards explained, to lead from the paint on the cars or on the tyres—as indicated by lead in the excreta and stipple cells in the blood, and that men at garages and stations where ethyl lead petrol was used showed a somewhat increased amount of apparent absorption and storage, but this effect was small as compared with the effect on workers who were subjected to other definite lead hazards. The committee was of opinion that at present there were no grounds for prohibiting the use of lead tetra-ethyl in motor fuel, provided its distribution and use were under proper regulations. The committee had suggested four sets of regulations—namely, for the manufacture and blending of the product, for its mixing with gasoline, for distribution, and for use in garages, service stations, and repair shops. These regulations were only of an advisory character, as the Federal Government had no power to make binding regulations for individual industries, and, so far as he knew, only one State had adopted them. But the Ethyl Gasoline Corporation had agreed with the Surgeon-General that the regulations regarding manufacture, mixing, and distribution should be carried out; so far as the fourth set was concerned, affecting the garages, there was no machinery for its enforcement, but it was issued as a warning to those concerned.

The witness added that since this inquiry further investigation on the men had been made, and they showed little or no more lead in the excreta than they did when first examined. They had now been under these conditions for four years. So far there was nothing to indicate that even in twenty years any more unfavourable result was likely to occur. In addition, certain private investigations and investigations by State medical officers had been carried out, and here again the results had been entirely negative.

In reply to Sir George Buchanan, the witness said that he was a whole-time medical officer in the Public Health Service, and if he had any bias it was the natural bias of the officer who would have to be "shot at" should any calamity occur. He did not think it was likely that there existed any unsuspected form of chronic poisoning, as had been suggested to the committee. Any such cases would certainly have been brought to the notice of those responsible for the inquiry, if only on account of the publicity given to the whole question in the States and to the instructions given to health officers everywhere to maintain a watch for such cases. The use of ethyl lead petrol had now spread so widely in America that it would be difficult in future to get controls—that is, to find garages where one could be sure that none of the product had been used. In reply to Sir William Willcox, he agreed that he had not examined the urine in the cases taken, but only the faeces; he believed that the excretion of lead through the kidney was more uniform than through the liver and other organs. Sir William Willcox also put it to the witness that where any toxic substance was acting in very small amounts, it might be extremely difficult to detect its cumulative effects, as instanced in the long unsuspected effects on aeroplane workers, during the war, of the tetrachlorethane in which the cellulose was formerly dissolved. The witness, in reply to Professor Dixon, said that so far as industrial medicine was concerned public health control in the States was not so well centred or so uniform as in this country, but from the point of view of the notification of unusual cases of disease or injury he thought there was no marked difference between the two administrations.

Sir Charles Martin referred to a suggestion made to the committee that cases of poisoning had occurred in America and had been hushed up and compensated by the important interests concerned. Dr. Leake agreed that that might be conceivable in the individual manufacturing plant, but so far as people working in garages were concerned nothing of the kind could take place. These people were in no way subject to control by the "interests." Industrial poisoning was compensated for by law in those States which had a body of industrial legislation.

\* Reports of the earlier proceedings have been published in the *British Medical Journal* of May 5th (p. 770), May 19th (p. 871), and June 16th (p. 1053).

SATURDAY, JUNE 23RD, 1928.

### TUMOURS OF THE FRONTAL LOBE.

THE steady progress of neuro-surgery has rendered the accurate localization of intracranial tumours a problem of urgent importance. As long as the surgeon could afford the patient merely a temporary reduction of his increased intracranial pressure by means of a cerebral decompression the precise localization of his tumour was of little more than academic interest. Modern surgical developments, however, are effecting as complete a revolution in the outlook of cerebral surgery as occurred in the surgery of the abdomen some thirty years ago. Owing largely to the work of Cushing and his pupils, the immediate mortality of operation for intracranial tumour is steadily falling, and in the most skilled hands is now less than 10 per cent. At the same time the technique of cerebral surgery is becoming increasingly radical. In a progressively larger number of cases the tumour is proving capable of removal. Histological studies indicate widely differing degrees of malignancy in the gliomas, many of which are slow-growing and relatively benign. Removal of such tumours may be expected to afford many years' relief from symptoms, and the possibilities of post-operative treatment with radium are still almost unexplored. But it is obvious that improved neuro-surgical technique can offer its benefits only to a patient whose tumour has been accurately localized, for, unlike the abdominal viscera, the cranial contents cannot be widely explored through a comparatively small incision.

In view of these considerations any data which promise to facilitate localization are of value, especially in the case of growths in the so-called silent areas, and we publish in this issue articles by Dr. J. Purdon Martin and Dr. S. McClements dealing with the symptomatology of tumours of the frontal lobes. From the investigation of their cases certain facts emerge which are perhaps worthy of emphasis. Dr. Martin rightly lays stress upon the slightness of the classical signs of increased intracranial pressure in many cases of frontal lobe tumour. Increased knowledge concerning the pathogenesis of these symptoms is bringing with it a recognition that headache, vomiting, and papilloedema are by no means constantly present nor always associated in cases of cerebral tumour, and that the presence or absence of these symptoms, taken in conjunction with the focal signs of the tumour, may have a certain localizing value. Thus papilloedema, though rare with frontal tumours, is, as Paton showed, common with tumours of the temporo-sphenoidal lobe. Also swelling of the optic disc is usually an early sign of cerebellar tumours, and in such cases attains considerable severity, while it is often absent or late in appearing when the tumour is situated within the pons. The frequent absence of papilloedema therefore distinguishes a tumour of the frontal lobes from temporo-sphenoidal and cerebellar tumours, with both of which it may sometimes be confused. Vomiting, though often described as a symptom of increased intracranial

pressure, appears always to be an indication that internal hydrocephalus is present, and the frequent absence of vomiting in frontal lobe tumours is to be attributed to the comparative remoteness of their situation from the ventricular and subarachnoid channels; hence the unlikelihood that such tumours will cause obstruction to the circulation of the cerebro-spinal fluid until they have attained a large size.

Another point of practical importance which Dr. Martin mentions is that generalized convulsions occurred in all three of his patients, and constituted an early symptom in two, one of whom also had attacks of the character of petit mal. It is too little appreciated that an intracranial tumour not infrequently gives rise to generalized epileptiform convulsions without any focal or Jacksonian element, and that, more than any others, tumours situated in the frontal lobe are prone to do so. Especially when generalized convulsions make their appearance for the first time in a patient over the age of 20 the possibility that they may be due to a cerebral tumour should be considered.

An important sign of frontal lobe lesions appears to have been absent in the cases now reported. This—the grasp or grip reflex—consists of an involuntary flexion of the fingers in response to the moving contact of an object with the palm of the hand, especially with the cutaneous surface between the thumb and index finger. This phenomenon may be discovered by the patient himself, who finds that he is unable to withdraw objects from the hand on the side opposite to the lesion. The harder he tries to pull away the object he is thus involuntarily grasping the more firmly do his fingers grip it. This remarkable reflex, which appears to be a regression to the reflex grasping of the young infant, is present in a proportion of cases of tumour of the frontal lobe, and appears to be pathognomonic of a lesion in that situation.

The mental changes which so often result from tumours involving one or other frontal lobe are of great importance in localization, and Dr. Ernest Sachs, in a recent review of the symptomatology of these tumours, found them present in twenty-one out of twenty-five cases. He, like Dr. Martin, stresses the "peculiar indifference" of these patients to their condition. That similar mental changes may be produced by tumours in other situations is doubtless due to the fact that in such cases increased intracranial pressure impairs the function of the frontal lobes. But then the signs of increased intracranial pressure are conspicuous, whereas when the mental impairment is due to a primary lesion of the frontal lobe these signs are slight or absent.

Lastly, it should be remembered that when clinical investigation yields an uncertain answer to the question of the localization of cerebral tumour, we have in ventriculography a valuable aid, of which increasing use is being made. The injection of air into the cerebral ventricles allows alterations in their size, shape, and position due to the pressure of a tumour to be demonstrated radiographically. Tumours of the frontal lobe are likely to cause deformity of the anterior horn of the homolateral ventricle, with possibly a displacement of the opposite anterior horn away from the tumour. Judging from the pathological reports, characteristic abnormalities would probably have been present in all three of Dr. Martin's cases had ventriculograms been taken. Ventriculography is especially useful when the clinical picture suggests that the tumour may be either frontal or cerebellar, for the

characteristic radiographic appearance of the latter is a generalized distension of the third and lateral ventricles, which can hardly occur as a result of a tumour of the frontal lobe. It must be added that both the injection of air within the ventricles and the interpretation of the resulting radiograms are procedures requiring expert knowledge, and ventriculography should be performed only when cerebral decompression can subsequently be done without delay should the patient's condition demand it.

### THE INTERPRETATION OF GASTRIC SYMPTOMS.

APART from the typical syndromes presented by organic lesions of the oesophagus, stomach, and duodenum, very few symptoms or groups of symptoms are of much value for the purpose of diagnosing disorders of the upper alimentary tract. Various names have been applied to diverse conditions thought to be associated with abnormality of motility or secretion in the stomach, but such terms as "acid or hypersthenic dyspepsia" and "flatulent dyspepsia" are at best merely cloaks for ignorance. That we are still very far from understanding this large group of clinical conditions is evident, if only from the frequency with which they resist all forms of treatment. Indeed, from the point of view of cure it is far preferable to deal with a frank peptic ulcer than with some of the so-called dyspepsias. Numerous efforts have in the past been made to determine the significance of symptoms which seemed to originate from the upper levels of the digestive tract. Notable among these attempts was the work of Head<sup>1</sup> towards the close of the last century on deep and referred pain, especially that dealing with the dyspepsias accompanying the various stages of phthisis. Mackenzie believed that all visceral pain was referred, and cited the frequent occurrence of gastric pain in the region of the xiphisternum considerably above the actual level of the stomach. But the newer methods of experiment employed by Cannon and Washburn and by Carlson, consisting in the investigation of pressure changes within a small elastic balloon at the end of a thin rubber tube introduced into the oesophagus or stomach, have necessitated the revision of older views. For example, the demonstration by this method that pain in the upper part of the epigastrium often originates from the lower end of the oesophagus seriously weakens Mackenzie's assumption regarding the nature of such pain.

Approaching the problem from its clinical aspect, Dr. Charles Bolton, in his Croonian Lectures (of which we gave a full abstract last week at page 1030), has analysed the position and time of onset of pain in over one thousand cases of dyspepsia. He described pyloric, cardiac, and oesophageal syndromes, the symptoms in each group depending upon undue irritability of the neuro-muscular mechanism in the wall of the viscus or upon abnormality of the gastric contents. In recent publications Payne and Poulton<sup>2</sup> have amplified our modern conception of dyspeptic symptoms by an experimental investigation of pain, heartburn, nausea, "sinking," and hunger. For these experiments the patient was gradually accustomed to the presence of a cylindrical balloon at various levels in the upper alimentary tract; pressure changes were recorded by water transmission to a

smoked drum, and simultaneous records were kept of sensations experienced. These workers found that oesophageal pain was due to stretching of certain nerve-endings in the wall, and that such pain might be relieved either by a peristaltic contraction relaxing the tension in the wall or by postural adaptation increasing the capacity of the viscus. Related also to the oesophagus is the sensation known as heartburn; this is associated with peristaltic contractions of the organ and a rise of pressure within it. Heartburn may be retrosternal or epigastric, and in this connexion it may be mentioned that the position of an oesophageal lesion can often be indicated with ease and accuracy by the patient. The sensation of nausea also is related to tension exercised on specific oesophageal nerve-endings, while the so-called "sinking" feeling is completely analogous, though arising from sensory nerve endings in the lower part of the stomach. Local conditions of heat or cold produced by swallowing liquids of varying temperature are capable of modifying tone and activity in the oesophagus, as also may reflexes through the fifth nerve or the cutaneous nerves supplying the sternal region. Pain is generally accompanied by increased oesophageal tonus, and the fact that the latter is diminished by counter-irritation probably accounts for the relief afforded by this therapeutic measure. In the upper abdomen pain is found to be commonly associated with movements of the pyloric portion of the stomach, duodenum, or jejunum. Conversely, where postural tone is low, pain may accompany relaxation rather than contraction of the muscular walls of the viscera.

These results may account in part for the spasmodic pain experienced in gastric or duodenal ulcer, and may in part also explain the more continuous discomfort so often felt in conditions of gastric atony as demonstrated by x-ray examination with the opaque meal. But it seems that there must be some factor other than peristaltic contractions in the production of ulcer pain, since alkalis relieve it without inhibiting peristalsis. It may be that heightened tonus, as in other parts of the digestive tract, is responsible for the pain in this region. Hunger pains are referred by the majority of subjects to the lower and mid-sternal regions, but they were shown by Cannon and Washburn<sup>3</sup> to originate from the contractions of the stomach, and also sometimes of the lower end of the oesophagus occurring in conjunction with increased tonus. These pains originate far more readily in the subjects of gastric or duodenal ulcer than in normal individuals, a fact which gives support to the view that the pain of peptic ulcer may be more closely related to the postural tone of the affected organ than to active muscular contractions of its walls.

#### DAWSON WILLIAMS MEMORIAL.

ALL the subscribers to the Dawson Williams Memorial Fund are invited to attend a meeting to be held at the house of the Royal Society of Medicine (1, Wimpole Street, W.1) on Tuesday, July 10th, at 5.30 p.m., to receive the treasurer's report and decide on the form of the memorial. The Organizing Committee suggests that it should be a prize to be awarded every two or more years for the best work which had been done in pediatrics since the previous award. The list of subscribers will remain open until July 10th, and contributors are invited to send their cheques to the honorary treasurer, Sir StClair Thomson (64, Wimpole Street, W.1) before that date, when the list must be finally closed.

## DIPHTHERIA IMMUNIZATION: THE QUEENSLAND FATALITIES.

According to the correspondent of the *Times* at Canberra, the Commission appointed by the Government of Australia to inquire into the cause of the deaths of twelve children at Bundaberg, Queensland, in January, during an anti-diphtheria campaign, has now produced its report, which has been tabled in the House of Representatives. When commenting previously on this fatality (February 4th, p. 193) we suggested that it appeared likely that the preparation used for prophylactic inoculation was the toxin-antitoxin mixture; this is now shown to have been the case. The mortality is attributed definitely in the report to the absence in the sample used of the antiseptic usually added to prevent the growth in the fluid of accidentally introduced micro-organisms; adverse comment is made upon the fact that there was no indication upon the bottle that the antiseptic was lacking. The Commission, which admits that its conclusions are based partly upon negative evidence, finds that pathogenic staphylococci were introduced somehow into the mixture, and all the evidence is said to favour the view that living staphylococci were the cause of the deaths. The way in which these organisms entered the mixture has not been defined with certainty; contamination of the hypodermic needle used may possibly have occurred, or the staphylococci may have been air-borne. The absence of disinfectant from the toxin-antitoxin mixture was intended as a safeguard against such dissociation as has been known to follow the freezing and thawing of this prophylactic. The repeated use of such a preparation was obviously open to a danger which would not have existed had the particular rubber-capped bottle been employed on only one occasion, as had been intended; the absence of a label indicating that no antiseptic was present gave, however, the unfortunate impression that the mixture—apparently a culture medium for organisms—was safeguarded from such contamination. The question, then, of the advisability of using toxin-antitoxin in diphtheria prophylaxis does not arise, the mortality at Bundaberg being accidental and having no real relation to the composition of the agent employed. This point is important and should not be overlooked, since already erroneous deductions in this respect have been drawn. The Commission unhesitatingly lays the blame on the absence of an antiseptic. Sir Neville Howse, Minister of Health, remarked advisedly that such antidiphtherial inoculation had been used all over the world without the procedure having been shown to be directly dangerous, and that this exceptional fatality indicated an unexpected complication. He went further, and added that the action of the staphylococci incriminated by the evidence was so unusual that an extensive investigation would be made of the pathogenic possibilities of this group of bacteria. It is a matter of common knowledge that staphylococci which in some past years were considered to have a very limited pathogenicity have latterly been shown to be capable of causing widespread and fatal morbid conditions. The unfortunate occurrence in Bundaberg is only another of a series of incidents all pointing in the same direction. Apart from this, however, it is stated by the *Times* correspondent that the Queensland Health Department has been recommended by the Commission to study the advisability of substituting toxoid (the *Times* report gives "antitoxin," which is probably meant for "anatoxine," the confusing word used in French literature) or a similar modified immunizing agent for toxin-antitoxin. Reference has been made to this question on several occasions in our columns, but it may be mentioned again that the employment of toxoid, and not toxin, in the mixture used in England appears to afford a wide margin of safety, provided that suitable antiseptic precautions are taken.

## THE INTERNATIONAL CONFERENCE ON CANCER.

The arrangements for the International Conference on Cancer, organized by the British Empire Cancer Campaign for the third week of July in London, are now practically complete. It promises to be not only a large gathering, but one which may have far-reaching effects. The programme of discussions and demonstrations planned is, I say the least, very comprehensive. On Monday, July 16th the international and imperial delegates are to be received at Buckingham Palace by the King, and in the evening that day Sir John Bland-Sutton, president of the conference, gives, with Lady Bland-Sutton, a reception at Broc Street. The business opens on the Tuesday morning at the Royal Society of Medicine and in the assembly hall of the adjacent College of Nursing. Tuesday and Thursday mornings are to be devoted to general discussions, and Wednesday and Friday mornings to sectional meetings. The principal general discussion is on the relative value of surgery and radiation in the treatment of cancer of the cervix uteri, rectum, breast, and buccal cavity. Dr. G. Regaud, director of the Pasteur Laboratory at the Paris Radium Institute, will contribute a general opening address, and each branch of the subject will be dealt with separately. Another general discussion will relate to the etiology of cancer, to be opened by Professor James Ewing of Cornell University, and this is to be followed by a third on methods of treatment by chemotherapy, with special reference to lead, the opener being Professor Blair Bell. On Wednesday and Friday mornings the conference divides into its six sections—namely, pathology, diagnosis, medicine, surgery, radiology, and statistics and public health—under the chairmanship respectively of Professor W. S. Lazarus-Barlow, Sir Thomas Horder, Sir William Hale White, Sir Charles Gordon-Watson, Professor Sidney Russ, and Dr. F. E. Fremantle, M.P. In the section on surgery the subjects to be discussed are the classification and treatment of bone sarcoma, and, on the second day, the early recognition and treatment of cancer of the stomach. The sections of medicine and diagnosis unite in one meeting for a discussion on some present-day medical aspects of cancer, and, together with the pathology section, for a discussion on diagnostic methods. The radiology section is to cover the biological effect of radium and x rays, with special reference to the factors of wave-length, intensity of radiation, and duration of exposure, and will also consider the effects of these agents on the blood, vascular, and lymphatic systems, with special reference to malignant growths. The sections of pathology and of statistics and public health combine for a discussion on occupational cancer, and the latter section is also to discuss geographical and racial prevalence, and public action with regard to the disease. The afternoons are to be devoted to demonstrations at hospitals and research institutions. Among the institutions to be visited are the Bland-Sutton Institute of Pathology and the newly opened Courtauld Institute of Biochemistry at Middlesex Hospital, the Royal College of Surgeons and its museum, St. Bartholomew's, Guy's, Westminster, St. Mark's, and the Cancer Hospitals, the Lister Institute, the Radium Institute, and the Wellcome Museum of Medical Science. Demonstrations, and in some places lectures and operations, have been arranged. The outstanding evening function is on Wednesday, when the Duke of York, President of the British Empire Cancer Campaign, will give a reception at Lancaster House, St. James's. About one hundred delegates from European countries, the United States, and the British Dominions have already intimated their intention of being present at the conference, and the list of these, with the much larger list of home delegates from the various hospitals and schools and public bodies, includes many names of national and international renown for work on cancer. The official

language of the conference is English, but arrangements have been made for translations when desired. It is intended afterwards to arrange for the special publication of as much of the proceedings as is practicable. The officers responsible, with the president, for this event in the history of cancer research and control are Mr. J. P. Lockhart-Mummery, chairman of the international conference committee, Mr. Cecil Rowntree, chairman of the executive subcommittee, and Sir Richard Garton, honorary secretary. The offices, from which further details can be obtained, are those of the British Empire Cancer Campaign at 19, Berkeley Street, W.

#### THE ROYAL MEDICAL BENEVOLENT FUND.

THE principal facts and figures relating to the year's work of the Royal Medical Benevolent Fund were furnished in our report of the annual meeting in March last (*Journal*, March 31st, p. 564), but the annual report of the Fund for 1927—the ninety-second to be published—which has just come to hand, contains many other interesting details. It includes, for example, summaries of certain cases relieved by the Fund; some of these make very pathetic reading, but there is here and there—what must be very sustaining to the officers and almoners—a vein of humour. Of the 150 pages of this book, about 100 are occupied with the list of individual and other subscribers. It is gratifying to note that the income for 1927 was increased by £800 as the result of allocations by the British Medical Association Charities Committee (as against £500 from this source in 1926), and by £625 from the Medical Insurance Agency, which has altogether contributed well over £5,000 to the Fund. The subscriptions and donations transmitted through the British Medical Association have shown an almost consistent increase during the last twenty years, and reached £1,271 in 1927. Certain Branches and Divisions of the Association, one of them the Malaya Branch, also subscribed a total of £84, and a sum not far short of £250 came from medical societies and hospital staffs, and £225 from Panel Committees. This last is a growing source of revenue; five Panel Committees each subscribed twenty guineas or over. The Liverpool Cathedral collection on St. Luke's Day resulted in £104 for the Fund. The historical retrospect shows that in the first year of the society's existence the income was £128; the income last year, for the general fund, was £13,576, and, in addition, the Guild, an invaluable auxiliary, had an income of £7,595; and as against the two cases relieved in the first year of operation, the number of grantees and annuitants is now over 600. With increased support from the profession at large much more could be done for those applying to the Fund for help in their distress.

#### ACCIDENT SERVICES IN INDUSTRY.

SEVERAL points of some medical interest were brought to light at the Industrial Safety Congress, organized by the Home Office and the National Safety First Association, which was held in London on March 20th; a report of the proceedings has now been published.<sup>1</sup> Mr. E. J. Fox, managing director of the Stanton Ironworks Company, described the system employed by this concern for dealing with accidents. Ambulance houses have been established at the various works, quarries, and pits; first-aid boxes are maintained, and outside visitors are employed to keep in touch with men who have been invalidated. Associated with the service are two consulting surgeons, who see between them practically every compensation case, and whose experience is available to the men's panel doctors in a consultative capacity. This facility, Mr. Fox said, was much appreciated by the local practitioners. Referring to the staffing of the ambulance

houses, he insisted on the importance of securing the best possible personnel—skilled trained hospital nurses. To the early attention given in cases of injury at the ambulance houses is attributed the substantial diminution which has been recorded since their inauguration in the number of cases classified as serious. Another speaker expressed the opinion that it was futile to have a safety organization without a well-equipped surgery, with whole-time attendants, open throughout the hours of work in the factory. In the establishment which he represented they insisted that every mishap, however slight, must be at once reported to the surgery. Three years ago they had discontinued entirely the use of first-aid boxes previously installed, and the result had been an enormous decrease in septic cases. This, it will be agreed, is a significant observation. Sir Alfred Herbert, in a paper dealing with machine tool design from the standpoint of safety, remarked that the oils, emulsions, or suds used on machine tools for cooling purposes in high-speed work seemed particularly prone to become contaminated by pyogenic bacteria, and workpeople exposed to contact with these fluids were very liable to develop boils.

#### THE PRESENT POSITION OF PRE-IMMUNIZATION WITH B.C.G.

PRE-IMMUNIZATION of infants by the B.C.G. (*Bacillus Calmette-Guérin*) seems to have aroused but little interest in this country. It is different in other countries, where the tuberculosis problem is, perhaps, more acute. Thus, in a communication to the Académie de Médecine in Paris<sup>2</sup> Drs. J. Cantacuzène and Jonescu Mihailesti described the results of the use of the method in some of the poorer districts in Bucarest and some of the provincial towns in Rumania since the early months of 1925. It appears that the inoculation of their infants with B.C.G. was readily accepted by Rumanian parents, refusals being encountered in only about 2 per cent. of cases. In one town it is recorded that every child born was vaccinated. By the end of last March 6,083 infants had undergone the treatment in Bucarest, and 3,191 in provincial towns. According to Drs. Cantacuzène and Jonescu, there has been a surprising reduction, not only in the tuberculosis mortality, but also in the general mortality, amongst vaccinated infants under 1 year of age as compared with the mortality in the non-vaccinated. Rates of 15, 24, and 26 per cent. in the latter are compared with rates of 5, 4.5, and 6.4 for infants who received B.C.G. The reduction applies to such diseases as broncho-pneumonia, in which the rate for the non-vaccinated is 5.5, while only 0.28 per cent. for the vaccinated, and "congenital debility," with the rate of 14.1 as compared with 2.3. The comparative death rates for vaccinated and non-vaccinated infants brought up in tuberculous surroundings could not be obtained for the provinces, but in Bucarest it was found that of 100 such infants 25 non-vaccinated died, and only 1 vaccinated. The observers regard the efficacy of B.C.G. as evident and its innocuousness as perfect. At the same session of the Académie Professor Lignières returned to his attack on Dr. Calmette's belief in the harmlessness of the administration of B.C.G. to infants who are brought up in non-tuberculous surroundings. Apparently Professor Lignières produced no direct evidence in support of his contention that harm arose from such administration, except that healthy inoculated calves sometimes had a recrudescence of swelling at the site of injection, accompanied by a rise in temperature, and that some guinea-pigs died unexpectedly. In fact, the professor's argument seemed to be that if a vaccinated child died of any disease its end might have been hastened by the vaccination with a living organism which was known to infect the lymphatic system. The other speakers at the meeting contented

<sup>1</sup> London: H. M. Stationery Office or through any bookseller. 1928. 9d. net.

<sup>2</sup> Bulletin de l'Académie de Médecine, May 15th, 1928.

themselves with pointing out that Professor Lignières had produced no evidence in support of this assumption. The chief defects in the presentation of their case by Dr. Calmette and his supporters seem to be, first, the somewhat startling assertion that ingestion of B.C.G. leads to a diminution, not only of tuberculosis, but also of general mortality; and secondly, the inadequacy, or worse, of their statistics. Those of Dr. Calmette were criticized in these columns by Professor Major Greenwood a few weeks ago.<sup>2</sup> The statistics of Dr. Jonescu are also unsatisfactory, in that the general mortality of all children under 1 year of age in Rumania is not stated. Moreover, it is astonishing to find that Dr. Jonescu is able to produce, as early as May 15th, statistics dealing with infantile mortality and the use of B.C.G. up to the end of last March. Dr. Calmette claims to have discovered a method for the prevention of tuberculosis in the young which, if valid, might be described as epoch-making. His discovery is considered worthy of much discussion in the Académie de Médecine in Paris, and this discussion is usually laudatory of what is regarded in France as an established truth. The method has been applied in many countries for the prevention of tuberculosis in cattle, and in some countries to a less extent for the pre-immunization of children. From many of these countries communications have been made, sometimes critical, at others extolling the method. The British contribution to the discussion seems limited at present to criticism of Dr. Calmette's statistics, which are obviously defective. It would be interesting to learn whether anyone in this country has had experience of Dr. Calmette's method, and, if so, with what results.

#### THE CORONER AGAIN.

IN an annotation on May 19th last (p. 864) dealing with an incident at an inquest held by the coroner for South-East London we remarked that "exemption from the necessity of attending before the coroner in future may be regarded from the personal aspect as a privilege rather than as a punishment." A further incident has speedily justified this comment. The body of a man who had committed suicide by cutting his throat was conveyed to the Lewisham Hospital. It was examined in the ambulance by one of the staff of that hospital, and sent on to the Lewisham mortuary. The doctor, giving evidence at the inquest, was seriously blamed by the coroner for not having gone to the mortuary to examine the body there. On his stating that he thought such an examination was under the jurisdiction of the coroner, and that he had no directions to go there, the coroner exclaimed: "I have never heard such foolish words in my life from a medical man!" The coroner is fortunate. Since, in the earlier case referred to, he had threatened pains and penalties to a doctor who had been present at the examination of a body without his permission, one can imagine what he would have said in this case if the doctor had in fact made an examination without it. It is indeed difficult, on reading the account of the inquest in the *Borough News* of June 6th, to see how the medical witness was in any way at fault. He had already testified that death was due to a large throat wound, sloping downwards to the right, deep, about four inches long, and involving the larynx and the jugular vein, and that this was consistent with it being self-inflicted, when the coroner told him, "You don't seem to know much about it," and sent him to the mortuary. He returned three-quarters of an hour later with the additional information that the "section edges of the wound were rather ragged." This seems to have satisfied the coroner, who recorded his verdict; but medical witnesses, even in the South-East London coroner's court, have a right to be treated with courtesy.

#### HARVEIAN SOCIETY OF LONDON.

THE annual dinner of the Harveian Society of London was held at the Connaught Rooms on June 14th, with the President, Dr. Herbert French, in the chair. The medical guests included Sir John Rose Bradford, President of the Royal College of Physicians, Sir E. Farquhar Buzzard, Regius Professor of Medicine at Oxford, Surgeon Vice-Admiral A. Gaskell, Medical Director-General, R.N., Lieut.-General Sir Matthew Fell, Director-General, A.M.S., Air Vice-Marshal David Munro, Director of Medical Services, R.A.F., Sir William Willcox, Sir James Berry, President of the Royal Society of Medicine, Mr. H. W. Carson, President of the Medical Society of London, and the presidents of several other medical societies. In proposing the toast of "The Harveian Society" Mr. Carson recalled that it was within three years of its centenary, that it had in the past survived two very critical periods for medical societies, and that now, like many kindred bodies, it was enjoying halcyon days of growing membership and increasing prosperity. He paid a tribute to Mr. Buckston Browne, who, among other generous gifts, had endowed a prize in memory of his only son. In the course of his reply Dr. Herbert French announced that the society's membership was now 300 and its finance sound. The present flourishing condition he attributed to the keenness of the officers (more especially the treasurer, Dr. G. de Bee Turtle) and to the participation of general practitioners in every discussion. The President added that all those present that evening were the guests of one member who had created a trust for the endowment of future dinners, and at his suggestion the health of this anonymous benefactor was toasted. Mr. C. W. G. Bryan, vice-president, welcomed the visitors in a witty speech, and the Right Hon. Augustine Birrell, K.C., Surgeon Vice-Admiral A. Gaskell, and Sir Henry Curtis-Bennett, K.C., responded. Mr. Birrell recalled that he had sat scores of times at the hospitable table of his old school-fellow Buckstone Browne, and chaffed previous speakers for omitting to mention the name of William Harvey at a dinner of the Harveian Society in the tercentenary year of the publication of *De Motu Cordis et Sanguinis*. Speaking as a writer, he assured them that the circulation of his books quickened the circulation of an author's blood. Admiral Gaskell briefly expressed a sailor's feelings when put up to reply between two eminent lawyers, and Sir Henry Curtis-Bennett rounded off a cheerful evening with some topical allusions.

#### THE INTERNATIONAL SOCIAL WELFARE FORTNIGHT IN PARIS.

AN International Social Welfare Fortnight will be opened in Paris on July 1st, and four important combined meetings will attract a very large number of visitors. The French Government is taking an active part in, and is helping to finance, this fortnight, and the chairman of the executive is a former Minister of Health, M. Paul Strauss. The meetings are: the International Housing and Town Planning Congress, of which the secretary is Mr. H. Chapman, 29, rue de Sévigné, Paris III; the International Congress on Statutory and Voluntary Assistance, the secretary of which is M. George Rondel, 49, rue de Miromesnil, Paris III; the International Child Welfare Congress, the secretary of which is Dr. Lesage, 37, Avenue Victor Emmanuel III, Paris VIII; and the International Conference on Social Work, the secretary of which is Dr. René Sand, The League of Red Cross Societies, 2, Avenue Velasquez, Paris VIII. Among the subjects to be discussed at this last conference are social work and public health; Dr. Kay Menzies is among the vice-presidents, and Dr. C. J. Thomas will read a paper on social work and school hygiene. Special arrangements have been made for reduced fares on the railways.

## THE WORK AND RESPONSIBILITIES OF THE PATHOLOGIST.

SIR BERNARD SPILSBURY'S ADDRESS TO THE RESEARCH  
DEFENCE SOCIETY.

THE second Stephen Paget Memorial Lecture was delivered at the annual meeting of the Research Defence Society on June 18th, by Sir BERNARD SPILSBURY, who spoke on "The work and responsibilities of the pathologist."

At the outset Sir Bernard Spilsbury defined a pathologist as a specialist in the study of the scientific aspects of disease, including the essential cause, the changes, visible and microscopical, produced, and the reactions provoked in the patient. The growth of scientific knowledge and of the laboratory method of investigation during the last fifty years had greatly increased the pathologist's labours and had brought about the division of the work between the pathologist (in the narrower sense of the term), the bacteriologist, and the chemist.

Sir Bernard Spilsbury then gave a few illustrations of the achievements of pathology in the study of the causes and processes of disease. The first was what he called the "romance" of anthrax. This disease had been recognized from very early times; the murrain of cattle recorded in Exodus was supposed to have been anthrax. In the middle of the last century the observation was made that minute bodies were observed microscopically in the blood of animals suffering from this disease, and it was stated that the blood which contained these bodies would produce the disease when injected into the healthy animal. The matter was still in dispute when Koch, in 1876, then a country practitioner in Germany, devised a method of growing the organism outside the body in broths and jellies, showed that these cultures had distinctive characters, and was able to reproduce the disease in healthy animals by injection. Koch's proof of the cause of anthrax was utilized by Pasteur, who had already begun his investigations on infectious disease, and he developed a method of protecting animals against infection. He experimented with cultures of the anthrax bacillus until he so reduced the virulence that on injection of the attenuated cultures into the healthy animals, those animals developed protective powers which enabled them to resist subsequent injection of virulent organisms. The result of the widespread adoption of protective inoculation was that the mortality in cattle and sheep from this cause had greatly diminished; in France it had been reduced to one-twentieth of what it was before inoculation methods were adopted.

Another illustration was hydrophobia, where Pasteur found that the virus was always present in the spinal cord of rabbits used in experiments, and that healthy dogs could readily be infected by injections made therefrom. He also found that the virus lost its strength with keeping, until after a time it failed to reproduce the disease on inoculation. Taking advantage of this fact, he injected into patients who had been bitten by rabid dogs preparations from the spinal cord of the experimental rabbits, using first very attenuated virus and repeating the injections with matter of increasing virulence, thus protecting the patient before the original disease had time to develop. The results of this treatment carried out in the Pasteur institutes in various parts of the world had been to reduce the fatalities to less than 1 per cent. of the patients treated.

In some infections the protective power was resident in the blood, and patients were treated by the injection of the serum of an animal which had been immunized against that particular infection. The immunization had been obtained by giving the animal a series of injections containing the organism or its specific toxin in carefully graduated doses, so that it developed substances which counteracted the effect of the poison, and presently gained complete protection. One of the most important applications of serum treatment was to diphtheria; it had been clearly proved that the mortality was greatly reduced by injection of the specific serum, especially if the patient was treated at an early age.

Part of the pathologist's routine work was to diagnose infectious disease by the discovery of the organisms, but

in some cases microscopical examination of the suspected material failed, and recourse had to be made to animal experiments. In early and obscure cases of tuberculosis, for example, to search for the organism by microscopical means was like searching for the needle in the haystack. In such cases injection of suspected material was made in the guinea-pig, which after a time was killed, and if the tubercle bacillus had been at work the characteristic changes were found. Another difficulty with which the pathologist had to contend was that some bacteria which produced specific disease had their innocent "doubles," and again it was animal experiment which enabled the problem to be solved.

A good deal of misconception existed with regard to animal inoculation. In the vast majority of cases the animal suffered no worse effect at the time of introduction of the material than the soon forgotten prick of the hypodermic needle. In some cases the development of the disease led to speedy death; in others, as in tuberculosis, the animal would presently show slight signs of disease sufficient to indicate that it should be destroyed and its dead body examined. It was only in a very small proportion of cases that serious suffering in the sense of pain attended inoculation experiments, and even then it was usually short-lived owing to the rapid progress of the disease.

Sir Bernard Spilsbury then mentioned some chemical problems which were presented to the pathologist, how, for example, by animal experiment, tetra-chlor-ethane was incriminated as the liver-damaging element in aeroplane "dope" during the war; also how experimental methods, again on animals, afforded the information required as to the hygienic measures to be adopted in factories against poisoning by T.N.T. Again, the experimental work by Dr. J. S. Haldane in connexion with carbon monoxide gas indicated the mechanism by which this form of poisoning acted, and his experiments on mice demonstrated once and for all the proper method of treating those who were suffering from its effects.

Practically the whole of bacteriological knowledge was based upon experimental work—inevitably so in the present state of affairs, for there were no means of testing the suspected organism except by the reproduction of the disease in living animals. The same was true of the diagnosis of disease. Every pathologist who worked alone, in a small hospital, found himself compelled to have a Home Office licence for vivisection if he was to do his duty to the patients in the diagnosis of obscure disease. For that reason, in recent years, the number of licences granted to pathologists all over the country had greatly increased. But chemical problems also required animal experimentation in such matters—for example, as the testing of new drugs. The pathologist was a medical practitioner, who, like his clinical colleague, had to apply his skill and knowledge to the best advantage on behalf of the patients. He must avoid error as far as possible, and must employ exact methods, including, at present, animal experiment. The scientific advances of the last fifty years, very largely based on experiment, had gone far to revolutionize the treatment of disease, so that there were some diseases, formerly rampant, with which the modern practitioner was scarcely acquainted. If only our forebears of last century could see the work which had been done in modern science and medicine, how they would exclaim at the enormous amount of suffering which, had they possessed the knowledge in their day, would have been prevented!

### *Antirvivisection Propaganda.*

In proposing a vote of thanks to Sir Bernard Spilsbury, Lord KNUTSFORD read to the meeting a postcard which had been sent out to the members of the British Union for the Abolition of Vivisection. The postcard stated that the Government, having removed the ban on the broadcasting of controversial matter, the British Broadcasting Corporation was now in a position to allow "our side" of the question of vivisection to be heard. But they would doubtless only do so if there was a sufficiently strong demand from the public. Members were therefore urged to write immediately to the Director of Talks, asking him to invite Dr. Hadwen to state the case against vivisection. The postcard continued: "You need not say that you are

a member of the British Union. Your letter will probably have more influence if the B.U.A.V. is not mentioned!"

Lord Knutsford added that he thought it a very regrettable action on the part of the antivivisectionists at Eastbourne that they should try to persuade people not to subscribe to hospitals which had a pathologist on their staffs. It was impossible to treat patients properly without such service, and if a hospital had no pathologist on its staff it must simply apply to another hospital which had.

At the business meeting of the Research Defence Society, which was presided over by Lord Lamington, one of the speakers was Mr. J. F. Peart, F.R.C.S., formerly a member of the staff of the Battersea General (Anti-Vivisection) Hospital. Mr. PEART said that as a member of the staff of that hospital he had signed a declaration that he would not assent to experiments on animals unless they were for the benefit of the animals concerned, and he had to undertake not to use any serums which had been prepared from living animals. He wished now to take the opportunity of publicly recanting his signature to that document, though he thought that he had "whitewashed" himself by the letter with which he accompanied it. On getting a case of tetanus into the hospital he found that he was not allowed to use any antitetanic serum. He appealed to the chairman of the board, Lord Tenterden, who did everything in his power to help him to get round the hospital statute, but in vain. He was forced to resort to using antitetanic serum surreptitiously. He felt very strongly that to send an accident case, which might be tetanus, to that hospital was like sending it to its death.

## SCOTTISH BOARD OF HEALTH.

### ANNUAL REPORT.

THE ninth annual report of the Scottish Board of Health, for the year 1927, recently issued, deals comprehensively with many vital questions of administration. It is pointed out that this will probably be the last report to be submitted by the Board, in consequence of the proposal before Parliament to establish in its place a Department of Health for Scotland.

### HOUSING.

The year 1927 marked a record in the history of house production in Scotland, the total number of working-class houses erected having been 21,660; it is anticipated that these results will be equalled in 1928. As 10,000 houses have been estimated as the annual requirement in Scotland, it follows that nearly 12,000 houses have been made available during 1927 towards the reduction of the housing shortage. The 2,000 steel houses mentioned in the last report were completed during the year, and readily obtained tenants. Further houses of this type are being built on the Springboig site in the vicinity of Glasgow. During the year five improvement schemes for slum clearance were confirmed in the burghs of Aberdeen, Fort William, Glasgow, and Kirkcaldy, while two Edinburgh schemes were under consideration at the end of the year. The number of houses to be closed was 11,935, and the schemes, which are to be carried out by the local authorities with the aid of a 50 per cent. grant from the State, are under the inspection of an officer of the department. An Act designed to improve housing accommodation for agricultural workers received the Royal Assent in December, 1926, and by December, 1927, schemes under this Act had been submitted by sixty-three local authorities and approved.

### PURIFICATION OF RIVERS.

The problem of river pollution is stated to become more pressing each year; over 800 instances of river pollution in Scotland had been investigated. This situation has been brought about by the hasty methods of sewage disposal which were adopted over a hundred years ago. The report reviews the history of the different methods of sewage purification which have been introduced from time to time in more recent years, and summarizes the conclusions which were reached by the Royal Commission on Sewage Disposal that sat from 1901 to 1915. It is intimated that, with the concurrence of the Secretary of State for Scotland, an advisory committee of eleven members, representative of all the interests concerned in the problem of preventing river pollution, has been appointed to advise the Board of Health on measures desirable for reducing pollution.

### INFECTIOUS DISEASES.

In the year 1926 a new low record was established by a death rate of 99 per 100,000 for all forms of tuberculosis, but

the same figure was repeated for 1927; the expected continued fall was not realized, while the pulmonary death rate actually rose from 69 to 71. An investigation was made of the treatment of tuberculous cases by the Ruppel antituberculosis serum (osmoserin). There was no evidence that the serum exerted a beneficial action in cases of non-pulmonary tuberculosis, although it proved, on the whole, to be an innocuous agent. With regard to venereal diseases, the report draws attention to the importance of education, both for the public and for medical students and practitioners, in this matter. The provision of facilities for treatment in Scotland may be regarded as reasonably complete. Attention is drawn to the important arrangements made by various local authorities of combining to establish centres or to utilize those established in central towns. The report states that, with very few exceptions, the records kept in the Scottish clinics are of high excellence. Complaints are from time to time received from various centres regarding patients who have received inefficient private treatment at a stage while disease is still in a curable form, and the report emphasizes the necessity for training medical students so that they may be able to treat the ordinary forms of these diseases with confidence and efficiency. The number of patients treated at venereal disease centres during the year ended May, 1927, was 24,731, including 13,976 new patients, while the total number of attendances was 397,611; the total cost of the schemes was £76,000, of which three-fourths was paid out of imperial taxation and one-fourth by local rating. With regard to other infectious diseases, there were 155 cases of small-pox in Scotland during 1927, the largest number in any year since 1920. All these cases occurred in Dundee or had been infected from a source in this town. The disease was of a mild type, and all cases recovered. There was a considerable reduction in the number of cases of measles reported from the sixteen principal towns of Scotland, but this was counterbalanced by a rise in the number of cases of whooping-cough. Diphtheria showed 7,548 cases in 1927, as compared with 6,021 in 1926, but scarlet fever showed only 10,609 cases in 1927, as compared with 13,667 in 1926. The practice of testing persons for susceptibility to scarlet fever and to diphtheria, and of immunizing susceptible persons against these diseases, continued to spread. It is pointed out that general practitioners who desire to immunize cases against these diseases should collect them and inject a number at one time, because the material for immunization very rapidly deteriorates. The outbreak of influenza in Scotland during January, 1927, and the subsequent months was the severest since 1924, although the disease was of a milder type than in the earlier year. Cases of encephalitis lethargica notified in the sixteen principal towns showed a considerable fall—from 260 in 1926 to 170 in 1927; cases appeared in a sporadic manner, without any outbreak of considerable dimensions. Many cases, however, are very slight, and do not secure medical recognition and official notification. The problem of dealing with cases in the later stages has given considerable anxiety. The parish council of Glasgow made arrangements in 1926 for the accommodation of fifty cases in the hospital at Stobhill, but the situation was not satisfactory, as there was a waiting list of suitable cases numbering 161. Some provision has also been made by the parish council of Aberdeen for the reception of a limited number. Infective jaundice, which was made notifiable in the Lothians in February, 1924, when 19 cases were notified, and which had subsequently been made notifiable throughout Scotland, with a notification of 52 cases in 1925 and 27 cases in 1926, produced only 1 notification in 1927. The results of a special investigation of Scottish cases carried out by Dr. George Buchanan have been published by the Medical Research Council. It has been confirmed that the rat acted as an animal reservoir of the spirochæte, but it has also been discovered that the organism exists in fungal slime hanging from the roof of certain coal mines and in pit and surface waters. Malaria and dysentery were made notifiable during 1927; no case of indigenous malaria was reported during the year, but it was considered that the presence of anopheline mosquitos in various parts of Scotland made infection with malaria a definite possibility. The total number of cases of infectious disease notified in 1926 in the counties, with a total population of 1,500,000, was 17,549, while in the burghs, with a population of 3,300,000, the corresponding number was 51,012. These are analysed in an appendix to the report.

### CO-OPERATION IN HOSPITAL SERVICES.

The report points out that there are in Scotland 25,000 beds for the hospital treatment of sick persons, excluding mental disease and hospitals provided by Government departments. Of these 9,000 are in voluntary hospitals, 10,000 are provided by public health local authorities, and 6,000 are in Poor Law hospitals or buildings. Voluntary authorities maintain 137 general hospitals, of which 26 have more than 100 beds, while local authorities maintain 250 hospitals, of which 23 have more than 100 beds, and in ten cases Poor Law hospitals exceed 100 beds. The six great teaching hospitals associated with

medical schools provide more than a third of the voluntary hospital accommodation in Scotland: The primary duty of the local authority in the provision of hospital beds is the obligation to maintain hospitals for infectious diseases, and the accommodation for tuberculosis alone accounts for 4,000 beds, of which the greater number have been provided in the last fifteen years. The Mackenzie Committee of the Board of Health reported that the additional beds required for voluntary hospitals amounted to 3,600, while the defect of the Poor Law provision was more a matter of inadequate standard than of numbers of beds. Aberdeen Parish Council has handed its hospitals over to the public health local authorities for administration, and these have been brought into relation with the teaching school of Aberdeen. Edinburgh Parish Council has under consideration the reorganization of its hospital provision, with the intention of providing a service of high quality. The report points out that there are numerous points of contact between the hospitals of different categories, and that there is nothing that ought to differentiate their function; as recent examples the new infirmaries at Stirling and Falkirk are pointed out; both provide beds for maternity cases and for venereal disease, by agreement with the local authorities of the areas served. Mention is made of the scheme under which the Glasgow Parish Council, in its hospital at Stobhill, makes available a considerable number of beds to the Glasgow Maternity Hospital for confinements; these are regarded as being an integral part of the latter institution. A practice which has grown up whereby individual members of the teaching staffs of the medical schools are employed in outlying hospitals has important results in keeping the standard of such hospitals in line with the best modern practice. Any effort, the report concludes, towards a better integration of the hospital service in an area must take into account the medical centre towards which these services are orientated: grouping should be considered in relation to the appropriate medical centre rather than to territorial divisions, such as county boundaries. On the invitation of the Secretary of State for Scotland a liaison committee of six representatives of voluntary hospitals has been appointed to keep the department in touch with voluntary hospital opinion in the five regions grouped round medical schools into which Scotland is naturally divided.

#### MATERNITY SERVICE AND CHILD WELFARE.

By the end of 1927 schemes of maternity service and child welfare were in operation in areas representing 93 per cent. of the total population of Scotland. The minimum provision of any approved scheme included home visitation by a health visitor; in many cases the part-time services of the district nurse have been utilized for this purpose. The number of health visitors employed by local authorities in 1927 was 136 whole-time and 450 part-time, equivalent in all to 230 whole-time visitors. Ultra-violet light installations had been approved at 23 centres for the treatment of mothers, and children under 5 years of age. Much ante-natal work had been done, and the experience of the 10 ante-natal clinics in Glasgow is quoted where, during 1927, the primary attendances numbered 5,983. The Board of Health, considering that an important factor in the reduction of maternal mortality in Scotland was the provision of trained nurses with specialized midwifery training, offered a grant of £20 per nurse to assist trained nurses to obtain the certificate of the Central Midwives Board, this grant being conditional on the nurse undertaking to serve two years in Scotland on maternity work. Thirty-nine applications were approved during the year. The number of practising midwives in Scotland on March 31st, 1927, was 4,250. During 1927, 622 women died in Scotland through diseases of pregnancy and childbirth, representing a death rate of 6.4 per 1,000 births, the rate for this year being the same as the average rate for the past ten years, notwithstanding the fact that the general death rate and infantile mortality were both decreasing. During the year 96,669 births were registered in Scotland, a rate of 19.8 per 1,000, as compared with 20.9 for 1926. The number of children under 1 year of age who had died was 8,577, representing an infantile mortality rate of 89 per 1,000 births. This is five less than the mean of the rates of the preceding ten years. The pre-school child under 5 years of age in 1927 formed 7.3 per cent. of the total population, and the death rate in this age group during the year gave a rate of 11 per 1,000, the same as for 1926, or 4 less than the average of the rates of the preceding ten years. Out of the total deaths of 4,103 in this age group 1,095 were due to pneumonia, 434 to measles, and 395 to whooping-cough. A special grant of £10,000 was distributed to local authorities for the specific purpose of securing greater efficiency in the control and treatment of measles and whooping-cough occurring in children under 5 years of age. This was secured particularly by removing a large number of cases of these diseases to hospital for treatment. There were 26 day nurseries in Scotland, most of which were in Glasgow, Edinburgh, and Dundee, and there was a large increase in attendance. Most of the large local authorities had developed arrangements for

mother-craft classes and for short courses of health lectures and demonstrations for women at their child welfare centres.

#### PUERPERAL SEPSIS.

Out of the 622 maternal deaths during 1927 in Scotland 184 were due to puerperal sepsis. This number, it is stated, gives no idea of the morbidity resulting from this disease, which ought to be to a large extent preventable. The death rate of 6 mothers per 1,000 births still remains much the same as it was a generation ago. The report considers polyvalent anti-streptococcal serum to be very useful as a preventive, but up to the present time the chief method of dealing with the problem has been to encourage ante-natal supervision. Frequent supervision of pregnant women is regarded as an important duty of the health visitor. Statistics have shown that in industrial areas there is an increasing tendency to engage the services of a midwife rather than a doctor for confinements, and it is pointed out that the midwife is prevented by law from undertaking any nursing or other duties which are likely to make her a carrier of infection. The report states that one of the most urgent requirements for a successful midwifery service is a great increase in the number of beds available, although most local authorities have made some provision in this respect.

#### FOOD SUPPLY.

Much has been done under the Milk and Dairies (Scotland) Act, which came into operation in September, 1925, to secure improvement in the milk supply of Scotland. It is recorded that outbreaks of milk-borne infection continued to occur in 1927. An outbreak of illness due to the *Bacillus enteritidis* Gaertner occurred in Dundee in October, and affected some 200 persons, the outbreak being traced back to a cow suffering from mastitis of the same form which had, in the previous year, caused an outbreak involving 370 cases of the same nature. During 1927, 2,240 cows were dealt with under the Tuberculosis Order, and it is considered that the removal of so many potential sources of infection must have had a great effect on the purity of milk supplies and on the health of the community. The Sale of Food and Drugs Act, 1927, has introduced some important regulations, and boric acid is now prohibited in all foods.

#### CONTRIBUTORY PENSIONS.

The economic position of the people of Scotland has been greatly affected already by the scheme of contributory pensions. The number of persons in respect of whom weekly payments are being made, including children, is estimated at over 150,000, equal to 3 per cent. of the population, or one person out of every twelve insured. It was expected that in Scotland about 51,000 persons would qualify for an old age pension payable at 65 on the commencing day, January 2nd, 1928.

#### NATIONAL HEALTH INSURANCE.

Dental benefit is said by the report to have improved by reason of the gratifying reception from Scottish approved societies of the scale of dentists' fees, conditions of service, etc., prepared towards the close of 1926. This has been adopted by 67 societies and 331 branches with a total membership of over 1,200,000, or approximately 80 per cent. of the membership of Scottish units giving dental benefits. The funds allocated to ophthalmic benefit appear in general to have been sufficient to provide grants to all claimants on the basis adopted by societies. The district medical officers have been increasingly employed because the heavy claims experience of societies frequently made it desirable to obtain second opinions on the condition of claimants for benefit. During the year 34,558 persons were referred by societies to the district medical officers. While women comprise only 33 per cent. of the insured population, they account for 57 per cent. of the references; during the year 40 per cent. of the women examined were pronounced to be capable of work, as compared with 33 per cent. of the men. Out of the total number of references only 510, or 1.4 per cent., were made by practitioners, and surprise is expressed that greater advantage was not taken by insurance practitioners of the facilities provided by the district medical service for obtaining, free of cost, second opinions in cases which may present difficulty. During 1927 insurance committees reported twenty-five complaints against insurance practitioners by insured persons or societies. Generally charges of neglect were found to be unsubstantiated, but in two cases fines of £10 and £50 were imposed. For charging fees to insured persons one practitioner was fined £5. One practitioner was fined £5 for failing to produce on request his records, and other fines were imposed for failure to transmit the medical records of patients whose names had been removed from the lists of practitioners. Some 40 out of the 2,000 practitioners in insurance practice were surcharged on account of over-prescribing, the total amount involved aggregating approximately £700. The surcharges had been imposed mainly in respect of unnecessary prescribing of flavouring agents, unnecessary elaboration of ingredients, and routine use of expensive ingredients where cheaper ingredients were available.

## India.

### Public Health Organization.

UNDER the Government of India Act, 1919, which embodied the Montagu-Chelmsford reform scheme and established the diarchic system in Indian administration, the responsibility for public health was, with certain reservations, transferred to the Provincial Governments. The Simon Commission will presumably be called upon to take cognizance of the effect in the sphere of public health of the big constitutional changes inaugurated in 1919, and a special interest therefore attaches to an extensive collection of articles published under the title of *Health Organization in British India*, in connexion with the interchange study tour in India, arranged by the Health Organization of the League of Nations for medical officers of health from the Far Eastern countries in the first two months of this year. Colonel J. D. Graham, C.I.E., I.M.S., Public Health Commissioner with the Government of India, who has acted as editor, contributes a review of the main central machinery, while other authors deal with the organization of their respective special sections in the leading territorial divisions. It is interesting to note that the resources and personnel available for research, cut down by the Incheape Retrenchment Committee in 1923, have now been restored almost entirely to the standard prevailing before the axe fell. Colonel Graham, discussing the future of health administration, notes "that, throughout the provinces, informed opinion is beginning to demand an expenditure on public health measures commensurate with their importance." He believes, however, that the Indianization of the Indian Medical Service to a fixed percentage on a time scale must hasten the decline of that service, which he considers is already in progress through difficulty in securing the desired type of officer. The effect of the division of powers under the diarchic system has been to leave the Government of India with its responsibility in health matters restricted to extra-provincial, inter-provincial, and international affairs, such as pilgrimages beyond the seas, quarantine, marine hospitals, census and statistics, and legislation for the control of epidemics. To the Provincial Governments were transferred the major part of the field of medical administration, including hospitals, dispensaries, and asylums, and provision for medical education, public health, sanitation, and vital statistics. The registration of medical practitioners is controlled by Provincial Medical Acts, but Colonel Graham states that an All-India Medical Registration Act is now under consideration of the Government. A scheme for the creation of an Imperial Research Institute is being evolved, and it is hoped that provision will be made for work on all aspects of the larger problems of disease as well as on the routine work, which is inevitably very great in a country like India.

### Increase in Tuberculosis in Bengal.

Tuberculosis of the lung appears to be very prevalent in Bengal. The report on hospitals and dispensaries in the province for 1926, presented by Major-General G. Tate, I.M.S., notes an increase in the attendance of patients suffering from this disease from 3,904 in 1925 to 4,117 in 1926 in the Calcutta hospitals, and from 8,292 in 1925 to 9,262 in 1926 in the district hospitals and dispensaries. There is a special unit for the treatment of the disease in the Medical College group of hospitals in Calcutta, but it contains only twenty-four beds. The intensive struggle for existence, trying climatic conditions, bad sanitation, overcrowding, inadequate food, and malaria are not only predisposing causes, but also militate against recovery. Some progress appears to have been made in the treatment of kala-azar following recent successful research work. Certain pentavalent antimony salts of relatively low toxicity have been discovered to have a rapid therapeutic action, and can be administered in much larger doses than the tartrate. There were severe outbreaks of cholera and beri-beri during the year in Calcutta; in the case of the latter only localized and sporadic outbreaks had occurred for several years, but in 1926 no fewer than 6,810 patients were treated. The Calcutta School of Tropical Medicine

has been able to demonstrate that the epidemic dropsy form of beri-beri is associated with the use of badly stored rice. The number of patients treated in district hospitals and dispensaries in allopathic institutions was 7,783,457, 2,115,764 being cases of malaria, and in Calcutta the number of patients was 553,521, 49,893 being cases of malaria. The incidence of this disease was therefore about three times as heavy in the outside districts as in Calcutta.

### Infant Welfare in India.

An interesting account of the progress of the infant welfare campaign in India has been published recently by Dr. Elizabeth Sloan Chesser in the *Revue Internationale de l'Enfant*. Dr. Chesser pays high tribute to the value in this respect of the Lady Reading Hospital in Simla, the Lady Hardinge Medical School in Delhi, and the movement organized by Indians in some of their States, particularly in Gwalior and Bhopal. The ignorance of the *dhai* (or midwife) is gradually being overcome by the efforts of trained welfare workers. In some hospitals rooms can be rented by women for their confinements, provision being made for the preparation of food by friends of the patient. Small maternity and child welfare centres now exist in several towns, and are staffed by trained *dhais* under an Indian superintendent. Although the career of a *dhai* is hereditary, and no sort of training existed up to recent years—midwifery being one of the "unclean" occupations—there is now a new spirit and a new hope for women in India, since these trained midwives fully appreciate the importance of cleanliness, and are provided with suitable equipments. In the large towns they are organized under the municipal authority, and the teaching of simple hygiene and child care is spreading. National "Baby Week" celebrations are becoming increasingly popular, and preventive work on ante-natal lines is being planned. By such means it is hoped that the very high infant mortality in the bazaar areas of the large towns will be reduced.

## Ireland.

### Royal Medical Benevolent Fund Society of Ireland.

At the annual meeting of the Royal Medical Benevolent Fund Society of Ireland, Mr. R. A. Stoney, vice-president of the Royal College of Surgeons, presided. The central committee, in submitting the eighty-sixth annual report, records with regret the deaths of several friends who have helped the society in past years. Dr. J. Singleton Darling of Lurgan, for many years honorary secretary of County Armagh (N.) branch, who died last autumn, was revered in the North of Ireland, and his personality was the strength of the branch. Another old friend was Dr. Richard Kinkaid of Galway; failing health during recent years had diminished his activity, but for several years he acted as one of the honorary secretaries of County Galway branch. Dr. H. Sneyd Torney of Terenure, did good service in reviving the Rathmines and Rathgar branch. By the death of Mr. John McArdle the Irish School of Medicine had lost a personality which had left its impress on the personnel of the profession throughout the land; he was a generous and sympathetic supporter of the Fund. The number of grants awarded during the year rose to 90 from 81 during the preceding year; the amount disbursed in grants was £2,071, as compared with £1,762 in 1926-27, an increase of £309. The average amount of the grants was £23 0s. 3d.; an increase of £1 4s. 6d. on the average recorded in the last report, and the recipients comprised 9 medical men, 11 orphans, and 70 widows. The balance sheet of the general fund shows receipts from all sources amounting to £2,481 8s. 11d.; the income from normal sources being £2,058 18s. 11d. Receipts from dividends and interest show an increase of £66 15s. 6d. The Irish Medical Association made the committee a grant of £10, and the British Medical Association allocated the sum of £60 from their Charities Fund. The year has been remarkable for the increase in the number of applications and for the urgency of the individual claims. The committee believes that if the members

of the medical profession could be brought to realize that many of the widows of their former colleagues are living in penury, that in some cases hunger haunts the orphans, and that broken and infirm medical men lack the minor comforts which would tend to ameliorate their lot, the apathy which exists towards the work of the Benevolent Fund year after year, noted in its reports, would vanish, and that the society would receive more general support. Those who know its work help it generously, but there is need for propaganda throughout the land to gather in new supporters. The report was adopted. Sir John William Moore announced that Mrs. Hepburn had left the society a substantial legacy running into four figures.

#### Health of School Children in Northern Ireland.

Speaking at a meeting of the North Antrim Regional Education Committee, Dr. Patrick of the Ministry of Home Affairs said that in this area they had 5,000 school children on an average in attendance. It had been found in other areas that there had been a very large number of minor ailments among these children which could easily be remedied once the necessity had been brought before the parents. It was largely a matter of education, since when it was explained to the people why these things were necessary the children would benefit. It was found in other areas in Northern Ireland that about 50 per cent. of the children were suffering from defective teeth, and this was really the most pressing problem. Moreover, about 30 per cent. of the children were suffering from throat diseases—serious conditions which ought to be remedied. Between 15 and 25 per cent. of the children had been discovered to be verminous; from 3 to 5 per cent. certainly, possibly 10 per cent., were suffering from minor defects of the eyes and were not able to read the school books; the parents did not realize as a rule that their children's eyes were defective. It was agreed to undertake the preliminary inspection of children, and for this purpose it was decided to arrange a conference with the dispensary doctors in the district to settle terms.

#### The Training and Examination of Nurses.

Dr. Edward Thompson, F.R.C.S.I., Omagh, in a recent communication to the press, refers to a Belfast newspaper report of the observations made by some of the Lurgan guardians about the failure of most of the probationer nurses trained in Belfast to pass their examination. Out of forty-two candidates only eighteen passed, and those were all being trained in Belfast institutions. Dr. Thompson states that he is not surprised at the failures, because some of the questions put would puzzle many qualified doctors and nurses. He quoted three of these questions: (1) Describe the coronary heart circulation; (2) What does the internal secretion of the ovaries consist of, and what action has it on the other organs of the body? (3) Enumerate the cranial nerves and give their distribution. He had a record of many other questions put to the probationer and senior nurses sent forward from the Tyrone County Hospital, but the examples he had given were enough to demonstrate the severity of the examination these young girls had to face. He admitted that the institution of these nursing councils had raised the standard of nursing, but there seemed a danger that if candidates were exposed to such exacting questions and there were so many rejections, they would become dispirited and their numbers would be greatly reduced.

#### Dispensary Doctors and Midwives (Irish Free State).

A letter with reference to the duties of dispensary medical officers has been received by the Clare Board of Health. Writing with reference to an application from a dispensary medical officer for payment of 8 guineas for acting as locum tenens for the local maternity nurse, the Minister for Local Government stated that he presumed his claim was in respect of the period during which the nurse had been on holiday, and for which period the doctor had agreed to do her duty. Such claim, continued the Minister, could not be entertained. A dispensary medical officer was responsible for the treatment of sick

poor in his district, who were entitled to gratuitous medical relief, and the services of a midwife did not relieve the medical officer of his responsibility, but were placed at his disposal to enable him to release himself from the necessity of attending cases in which no difficulty arose. If the services of a midwife were authorized for a dispensary district, and she was not available, for any particular reason, to attend a patient, it was the duty of the medical officer to attend such patient, or, if necessary, to requisition the assistance officer to procure the services of a temporary midwife.

#### St. Ultan's Infant Hospital, Dublin.

The annual general meeting of St. Ultan's Infant Hospital, Charlemont Street, Dublin, was held on May 31st. The report indicated the great progress made during the nine years of its existence, and stress was laid by the speakers on the importance of the extern department in a hospital of this kind. During the past year 4,210 patients under 5 had been treated in this department, in spite of the difficulty due to building operations; the new wing, when completed, would provide much needed facilities. After the meeting those present visited this new wing, now nearing completion. The ground floor will be occupied by the out-patient department, which includes, among other special features, extensive accommodation for perambulators. On the upper floor there is a theatre block, a new diet kitchen, and small individual wards for premature infants opening on to a special balcony. The new wing is glazed with "vita" glass, and last November the western windows of the main building were glazed similarly. This hospital, which was opened in 1919, admits to its wards no patient over 12 months of age, and in this respect differs from all other hospitals in Ireland.

## England and Wales.

#### Welsh Board of Health.

The Minister of Health has approved the following arrangements for the organization and conduct of the work of the Welsh Board of Health, consequent upon the retirement next week of Sir Thomas Hughes from the public service. The Board will henceforth consist of three members: Mr. John Rowland, C.B., Dr. Llewellyn Williams, and Mr. Howell E. James. Mr. Rowland and Dr. Llewellyn Williams will continue to exercise the functions heretofore assigned to them as Deputy Controller of Insurance and Medical Member of the Board respectively. Mr. Howell James will become a member of the Board, and will cease to be secretary and *ex officio* member of the Board. Mr. Rowland, as senior member of the Board, or, in his absence, the member next in seniority, will preside at Board meetings. Mr. Rowland will succeed Sir Thomas Hughes as deputy for the Welsh member of the National Health Insurance Joint Committee.

#### The Courtauld Institute of Biochemistry.

A description was given in our last issue (p. 1044) of the new Samuel Augustino Courtauld Institute of Biochemistry at Middlesex Hospital. The opening ceremony on June 14th, at which Prince Arthur of Connaught presided, was notable for the announcement of another generous gift by Mr. Courtauld of £20,000 for the maintenance of the Institute, in addition to the £40,000 he has already given for its construction and equipment. Mr. Courtauld explained that he had been led to make this gift partly by the recollection of a cottage hospital in Essex, started and maintained more than half a century ago by his parents. As a small child he was taken to inspect the surgical instruments, which no doubt would be judged antiquated to-day, kept under the care of a motherly nurse equally antiquated. But another reason had prompted him to this gift—namely, that during his business life the success he had attained had depended largely on the application of science to industry. Very

often such research ended in failure, sometimes in success, and sometimes in a negative result, which was still valuable because it narrowed the field of further inquiry. He had a profound sense of the value of research, and he quoted a line from Virgil, "*Felix qui potuit rerum cognoscere causas, atque melius omnes et inexorabile fatum subjecit pedibus*," and added that perhaps one might say, more blessed still was he who was enabled to know something more of the science of medicine and to overcome the ills of humanity which were due to pain and disease. Prince Arthur of Connaught, as chairman of Middlesex Hospital, accepted the Institute on behalf of the hospital with appropriate expressions of gratitude, and Mr. Asher did the same on behalf of the medical school. The latter said that the building was linked by a bridge and a subway to the Bland-Sutton Institute of Pathology, but it was linked also by something much more substantial—the cordial co-operation of the professors in the different departments and the spirit of endeavour which gave promise of great achievement. The Institute, said Mr. Asher, represented almost a magical combination of the right moment, the right place, and the right design. In the course of the proceedings Sir Archibald Garrod gave an address on "The place of biochemistry in medicine," which we hope shortly to publish in full. A vote of thanks to the lecturer was spoken to by Sir John Bland-Sutton, who described him as the natural successor of William Prout and Henry Benze Jones, and by Professor Dadds, who said that after hearing Sir Archibald Garrod describe what had been accomplished by the old physicians who had, in or near their consulting room, a shelf with a few bottles, a spirit-lamp, and some test-tubes with which to prove certain chemical examinations, he was appalled to think what would be expected of that great institute of which the shelf was the prototype.

#### A Plea for Biology.

The annual conference of education authorities, held recently at Bath, was noteworthy for a striking address by Professor Julian Huxley, in the course of which he made a strong plea for the making of biology a central subject in the educational curriculum. Biology, he said, was just attaining its maturity. Each of the many branches of the subject now had its repercussions on every other branch. Since 1800 great strides forward had been made. The whole of the essential mechanism of heredity transmission had been discovered; also the essentials of that mysterious problem the determination of sex. An enormous advance had been made in the study of the chemistry of life and its bearing upon physiology and medicine, and innumerable gaps had been filled up in the study of evolution, especially from the examination of fossils. The science of development had been lifted from what was a chaotic and rather mysterious realm into something where at least certain general principles could be appreciated. The twentieth century, Professor Huxley continued, seemed likely to be the century of biology and its applications, as the preceding century was the century of chemistry and physics and their applications. He reminded his audience that many Government departments were clamouring for trained biologists to go into the Empire and take charge of work in entomology, agriculture, fisheries, animal breeding, various applications of biochemistry, as well as hygiene and tropical medicine, this at a time when, in applied chemistry and engineering, the market was overstocked. He stated further that the knowledge of biology was becoming more and more necessary as a basis for citizenship. To have a sound and sensible judgement of such problems as population, the unfit, birth control, and private and public health, it was necessary to have a knowledge of the scientific principles which such problems involved—that is to say, the biological sciences. Professor Huxley predicted that in another decade any reasonable and informed discussion of the political problems of the day would demand the biological background if the discussion was to be effective. He then went on to ask what the schools were doing in respect to biology. The public schools taught biology largely because they found it necessary in training those of their scholars who were going on to medical study. In the secondary schools, however,

he found very little biology in the modern sense of the word; botany and geology were taught, and a few other subjects, but the interconnexion was not made plain. It difficultly was to find space in the curriculum. Physics and chemistry, owing to their success during the last quarter of a century, were standing in the way of biology finding its proper place, just as classics and history stood in the way of physics and chemistry thirty years ago. What was wanted, said Professor Huxley, was general biological teaching for the average child—not merely the scholarship child—not dollops of botany and slices of geology, but biology as an interconnected whole. A lump of coal was geology, botany, chemistry, and economic geology. The human eye was physiology, physical optics, and evolution. Bacteria were botany, chemistry, hygiene, and ecology. When he said that biology must be a central subject in education he explained that he did not mean that it should be the largest subject, only that it should be central in position, because it was a subject which linked up so many others. It was the only link between the science of matter—that is, physics and chemistry—and the science of mind—psychology; and it was the basis of agriculture, veterinary, and medical sciences and sociology. Mr. T. Loveday, the vice-chancellor of Bristol University, who presided on the occasion of Professor Huxley's lecture, said that the universities were having a surplusage of men who were trained in mathematics, physics, and chemistry and at Bristol every opportunity had been taken to "orient" men towards the biological sciences, in which there were more and more openings every year.

#### Inquests in the City and Southwark.

In Dr. P. J. Waldo's annual report for 1927 it is stated that 545 inquiries were held in districts for which he is coroner—namely, the City of London, including Holloway Prison, and Southwark. Necropsies were performed in all except twenty-seven cases. Of six bodies recovered from the river, five were identified by means of the special City formalin preserving apparatus. The action of the formalin—apart from its disinfecting properties—is to render previously unrecognizable bodies recognizable. Verdicts of death from suicide were returned in twenty-four cases (19 males and 5 females). The cost of the inquests amounted to £794 in the City, and £657 in Southwark. It is noted that 63 fatalities were due to road vehicles, and that in 20 of these cases death was caused by commercial motor vans or lorries (all without side guards, which are compulsory in the case of omnibuses). One inquest only was held on an infant accidentally suffocated while in bed with the parents; in this instance there was no room for a cot or cradle. Inquests were held in 21 cases of sudden death caused or accelerated, by the administration of anaesthetics for necessary surgical operations. Ether was given in 11 cases, chloroform in 3, a mixture of chloroform and ether in 1, gas and oxygen in 1, and in the remaining case death was caused by an accidental overdose of carbon dioxide. Whereas, in former years, a large majority of these deaths were attributable to chloroform or a mixture containing chloroform, in recent years ether generally has taken the place of chloroform as a fatal factor in this class of case. The Coroners (Amendment) Act came into full force on May 1st, 1927; one result of the new Act has been to increase largely the work and expenses of the coroner in both the City and Southwark.

#### St. Mary's Hospital Medical School.

At the presentation of prizes and awards by Lady Iveagh, M.P., at St. Mary's Hospital Medical School, on June 14th, several references were made to the relations between the public and the medical schools. The dean, Dr. C. M. Wilson, mentioned that Lord and Lady Iveagh have been for many years associated with the work of Sir Almroth Wright, and said it was fitting that she should be present when preparations were being made to build a permanent home for his department. They needed, he said, £100,000, and he reminded his hearers that not one penny that was contributed to the hospital was available for the school. Their first contribution was £20,000 from an anonymous donor interested in Sir Almroth Wright's work; Sir

Almroth's committee had promised them £20,000 subject to certain conditions, and they had now £51,000 towards their fund, although they had hardly begun to ask for money. They wanted to convince public opinion that opportunity for medical education and research supported properly was the best investment the nation could make. Lady Iveagh said that the public had no idea of their duty to medical education; many thought that in contributing to the voluntary hospitals they were contributing to the medical schools.

#### The Tuberculin Dispensary.

The second annual report of the Tuberculin Dispensary Benevolent Society states that work at the dispensary at 32, Fitzroy Street, Fitzroy Square, London, W.1, has made steady and satisfactory progress, though not rapid enough to satisfy its promoters. Reference is made to the lack of support by medical practitioners, and attention is drawn to the economic advantages of tuberculin therapy, particularly in the case of the poorer patients, who are able to remain at their usual occupations while being treated. Increased funds are required for the dispensary, and regret is expressed that more support has not been forthcoming from public authorities. During the year under review 110 patients visited the dispensary, but many were in too advanced a condition for treatment to be undertaken hopefully. Fourteen cases which had been diagnosed as having early signs of tuberculosis were proved negative on testing. Dr. Camac Wilkinson mentions with regret that only in one instance was assistance received from any of the friendly societies. He invites an unbiased and judicial investigation of tuberculin treatment on the lines employed at the dispensary. At the annual meeting of the Tuberculin Dispensary Benevolent Society it was agreed that steps should be taken to terminate its existence as a friendly society and to reconstitute it in its earlier form as an independent tuberculin dispensary for the poor.

#### The Victoria Hospital for Children.

Increased activity is recorded in the annual report for 1927 of the Victoria Hospital for Children, Tite Street, Chelsea. The daily average number of occupied beds was 105.22, against 89.13 in 1926, while the number of children resident during the year was 3,753 against 1,677 in 1926. This increase has been due largely to the fact that the new special ward, for tonsil and adenoid cases was, for the first time, open throughout the year. It is interesting to note that the average cost per in-patient per week has been reduced by over 4s. 6d. to £3 1s. 3½d. In the out-patient department the work done also showed some expansion; the number of new patients was 12,338 and the number of attendances 82,563, as compared with 12,163 new patients and 75,029 attendances in the previous year. Here also an addition to the hospital's facilities, in the form of the artificial light extension, which was opened early in 1927, brought about an increase in the demand for its services. The convalescent home at Broadstairs continues its useful work as an adjunct to the hospital. In its finances the hospital has been faced with a deficit on the year's working, the cost of maintenance being over £422 above the income for the year of £21,707, and there was a bank overdraft at the close of the year of over £4,123. An appeal is made for further annual subscriptions, and this report points out that special efforts involve additional expenditure and yield income which can only be regarded as of a temporary nature.

#### Memorial to Dr. Iris Fox.

A fund is being raised to erect a permanent memorial to the late Dr. C. Iris Fox who died from septicaemia contracted in the course of her work at the Royal Free Hospital. An account of her career was published on January 30th, 1926 (p. 222). It is intended that the memorial should be associated with the pathological department at the Royal Free Hospital, where Dr. Fox was senior assistant pathologist at the time of her death. The extension of the department is now under consideration, and it is hoped that enough money may be raised by the

subscriptions of her friends and former students to build and equip a laboratory or library for research, to bear her name. Donations should be made payable to the "Iris Fox Memorial Fund," and sent to Miss Lorel Goodfellow, honorary secretary and treasurer, Flat 3, 28, John Street, Bedford Row, W.C.1. It may be added that in connexion with the general appeal for funds for the extension of the pathological department a circular letter has been addressed to past and present students of the London School of Medicine for Women, pointing out that support from the general public is difficult to obtain since few appreciate the importance of pathology or the extent to which it contributes to successful treatment.

## Correspondence.

### ABDOMINAL PAIN AS EXEMPLIFIED IN ACUTE APPENDICITIS.

SIR,—Under the heading of "Research by observation," in the *Journal* of May 26th (p. 966), you make some pertinent editorial comments on a paper of mine in the same issue (p. 887) dealing with abdominal pain. In the course of these comments you mention certain observations which are difficult to reconcile with the observations and the thesis set forth in my paper, and I would ask your indulgence that I may deal with some of the points you raise.

You ask, "Is muscular rigidity, familiar as a clinical sign of gastric and duodenal ulceration, dependent on stimulation of the [parietal] peritoneum?" In my experience true reflex involuntary muscular rigidity, strictly comparable with that found over an acutely inflamed appendix, is not a feature of gastric or duodenal ulcers, unless there has been a slight leak from a pin-point perforation, or perforation of an ulcer on the anterior wall is imminent, and I feel sure that where met with it does signify stimulation of the parietal peritoneum. But deep tenderness, associated with a slighter degree of muscular resistance or "guarding," is frequently present, and the evidence from the examination of these ulcer cases under the fluorescent screen is quite definite. The tender spot is almost invariably found over the actual ulcer crater. Now we know that the stomach and duodenum are not themselves tender on pressure, even though ulcerated. My conclusion is that when the radiologist elicits a tender spot on pressure over the ulcer he is pressing the sensitive parietal peritoneum into a position in which it receives some degree of irritation from contact with the ulcerated area. In this connexion it should be remembered that Mackenzie's observations on the areas of tenderness associated with gastric and duodenal ulcers were made before the modern developments of radiological technique, which have altered so profoundly our conception of the anatomy of the stomach in the living patient.

You also mention the difficulty of muscular rigidity associated with tonic spasm of the ureteral muscle, and of the viscerosensory reflexes associated with bladder and prostatic lesions. My paper was an attempt to establish the mechanism of pain in the gastro-intestinal tract, and I do not think that we are justified in arguing from the urinary system. There are certain fundamental differences between the two systems which invalidate any such argument by analogy. One is that the bladder and prostate, unlike the gastro-intestinal tract, are very sensitive to direct mechanical stimulation, as any surgeon knows who has opened a bladder under local anaesthesia of the abdominal wall alone for suprapubic drainage and explored the upper surface of the prostate and base of the bladder with his finger. Penile-tip pain is at once felt. Another difference between the urinary and gastro-intestinal tracts is the strictly extraperitoneal position of the urinary system.

Again, in reply to your mention of the viscerosensory reflexes of cardiac disease, I believe that the argument by analogy from the cardio-vascular to the gastro-intestinal system is dangerous and tends to confusion of thought. Much of Mackenzie's theory with regard to abdominal pain

was undoubtedly based on his observations of cases of angina and aneurysm, and I suggest that this train of thought led him astray.

The "tenderness in the scalp related with visceral stimuli in the whole vagus field" is a phenomenon with which I have only a textbook acquaintance. My lack of any clinical experience of it leads me to believe that it is a rare phenomenon, and therefore not one on which an important physiological argument can lightly be based. I tried in my paper to argue from phenomena such as are met with in the routine clinical work of any general surgeon.

In reference to the deep tenderness over an area of pleuritic inflammation you find a difficulty in the fact that with the outpouring of fluid this tenderness disappears, though it may be only up to the level of that fluid. I am bound to accept the pleural cavity as germane to the argument, since it is developed from the peritoneal cavity, but the fact that you mention seems to me not a difficulty but a confirmation of my thesis. As the fluid collects it separates the visceral from the parietal pleura, and so stops the friction of the parietal pleura, which is the source, by pleuro-cutaneous radiation, of the deep tenderness.

A theory such as Mackenzie's theory of referred pain when once it has become orthodox dies hard, and it is right that we should be very critical of new and possibly subversive doctrines. But if the unity of the gastrointestinal tract be granted I feel confident that an unbiased study of the clinical and operative phenomena available will lead to the general conviction that we have been trusting to a theory of reflexes that does darken counsel, and that the true mechanism of abdominal pain is simpler than Mackenzie believed.—I am, etc.,

Manchester, June 8th.

JOHN MOHLEY.

#### **PATHOGENESIS OF ACUTE PRIMARY GLAUCOMA.**

SIR,—There are one or two points in Mr. Duke-Elder's letter (June 9th, p. 1000) which call for reply. He has instanced the wide differences of measurement, but those methods used for measuring capillary pressure which give high readings are open to the criticism that they stop the flow, produce banking up, and so measure the pressure in the arteries—kinetic energy of flow being converted into static energy. The least equivocal methods give the low readings—for example, that of finding the countervailing pressure which stops bleeding from a small cut in the finger, such a cut undoubtedly severing arterioles as well as capillaries. Also the method of introducing a quartz micro-pipette into a branch of a capillary network, and finding the pressure which just prevents entry of blood corpuscles into the pipette. Both these methods have been applied to human skin. Landis introduced such a pipette into what he calls arterial capillaries found in the mesentery of the frog. These are straight vessels, usually unbranched, and like arterioles. He has measured the systolic pressure by forcing a dye into the vessel. Now the pipette both occupies room in the vessel and obstructs flow, and banking up is produced by injection. The systolic pressure so measured is much too high, but it comes into his calculation of the average normal lateral pressure of the capillaries. He also introduced the pipette into a branch of a net of what he calls venous capillaries. This would give a much more accurate reading, but not differentiating one set of readings from the other he gives an average of them all, and this must therefore be too high. His method of measuring the passage in or out of fluid from a capillary is no less open to criticism, as shown in the papers by J. McQueen and myself, which are appearing in the next number of the *British Journal of Experimental Pathology*.

One important factor generally left out of reckoning is the counterbalancing pressure of the tissues. The capillary pressure can rise to considerable heights under certain conditions, such as obstruction of the veins, but as the tissues are confined by membranes the tissue pressure rises concomitantly. In the eye the pressure of the humours counterbalances that of the minute vessels, and a very small excess suffices to maintain velocity of flow. If the aqueous

fluid be let out and the abdomen be compressed the iris swells up, and the minute blood vessels, no longer supported by the counterbalancing pressure, may burst. In the kidney the fluid in the capsules counterbalances the pressure in the glomerular capillaries.

The method which I use for measuring capillary pressure is the same as that used in measuring blood pressure in the arm by means of the pneumatic cuff and manometer, the only difference being that the indices of capillary pressure are observed under the microscope. There is abundant proof that this method is fairly accurate, and I apply it to higher animals, mice and bats, no less than to frogs and toads. The capillary pressure in the minute capillaries of the fat in the mesentery of a mouse is lower than that in the big capillaries of a frog.—I am, etc.,

London, N.W.3, June 18th.

LEONARD HILL.

SIR.—Mr. W. S. Duke-Elder, in the opening paragraph of his letter (June 9th, p. 1000), states:

"Dr. Ramsay suggested that the evidence was in favour of the formation of this fluid by dialysis in the same manner as the other tissue fluids, and to this Dr. McQueen objects on two grounds: first, that there is not a sufficient pressure in the capillaries of the eye to allow such dialysis, and secondly, that the aqueous humour is formed in quantity too great to be accounted for in this way."

Mr. Duke-Elder's paraphrase of my letter is quite an erroneous one. I did not confuse filtration with dialysis.

By filtration is meant the passage of fluid through a membrane as a result of a difference of hydrostatic pressure on the two sides. (Waymouth Reid in Schäfer's *Textbook of Physiology*, vol. i, p. 280.) Dialysis or dialysis does not imply a difference of hydrostatic pressure on two sides of a membrane. Krogh (1922) is also misquoted.

Landis, in 1927 paper (*American Journal of Physiology*, vol. lxxxii, p. 217 et seq.), which is the important paper dealing with passage of tissue fluids, never found how much the pressure in the "arterial capillaries" was above the tissue pressure because he never measured the tissue pressure. The osmotic pressure of the tissue fluids in the frog would not be overcome by 145 mm. of H<sub>2</sub>O as stated by Mr. Duke-Elder. As regards the supposed pressure gradient of 22 to 28 mm. of Hg in the capillaries of the eyeball, I did not argue from analogy solely, as anyone can see who reads more of the paragraph than Mr. Duke-Elder quotes.—I am, etc.,

Hale-sowen, June 15th.

JAMES M. McQUEEN.

#### **THE FUTURE OF OBSTETRICS.**

SIR,—In India little girls of 6 years old are married to men of 40 years of age, and many little children join the cruel and awful ranks of widowhood before they have menstruated. This is done, and approved of, in the sacred name of religion. In England men and women are allowed to qualify and try to perform the most difficult operations in obstetrics in the most unfavourable surroundings, after having completed at most two months of practical midwifery and after having delivered perhaps less than ten cases. People can get used to and approve anything.

The maternal death rate in Siam is ten times as great as that of England (at least 40 per 1,000). The point I want to make is this: although every law of hygiene is broken, although clothes and rags and filthy nails are scraped around the vagina and sometimes even into the uterus, yet 950 out of 1,000 women survive. The converse is equally true. Because only 4 women out of every 1,000 die in England it does not mean that the other 996 had a safe confinement. I am firmly convinced that no woman who has to submit to any form of interference has as safe a confinement as possible. Every vaginal examination is potentially dangerous, and they are absolutely unnecessary in over 90 per cent. of all cases. It is precisely those cases of labour which are normal, or vary but little from the normal, which require so many months of the student's time to master, and which are so liable to lead him into excessive interference in his practice.

The whole crux of the matter is that the student is practically ignorant so far as midwifery is concerned when he

qualifies. It is high time that every unit of the medical profession faced the facts and insisted on a longer and more practical course in obstetrics. It will then be realized that until about three times as many beds are available for the instruction of medical students the desired improvement is impossible. The necessary hospitals might be built by private companies, for I am sure they could be run at a profit, or they might be obtained by the conversion of existing infirmaries. The important point is that the medical profession should be unanimous in demanding that they should be obtained and that the ridiculously inadequate training in obstetrics should be recognized and altered.

Professor Mellor in your issue of March 17th (p. 467) writes that "British midwifery is the admiration of the world." I am sure she has adequate evidence for that statement. Whatever it is the world admires it certainly is not the institutions, for we have none that can compare with the admirable clinics of such places as Leipzig, Berlin, or Vienna, or even, as far as equipment goes, with the Government Hospital, Madras. I do not think that either we ourselves or the world can admire our results or the amount of research work carried out in Great Britain on obstetric subjects. Let us rather determine that British obstetrics shall again be the admiration of the world, as it once was.

We spend enormous sums of money on cancer research which may or may not be the means of saving lives. Shall we refuse to spend money in preventing the wastage of the mothers of England just because we know the causes of their deaths and could prevent them? The plain unvarnished truth is that there is not the money, there are not the institutions, and there are therefore not the facilities for adequate instruction or effective research.

It is because Dr. Cressy, in his courteous reply (March 10th, p. 412) to my letter published in your issue of February 18th (p. 284), failed to answer my two questions that I have ventured to refer once again to what, I am sure, is the root of our obstetric evils.—I am, etc.,

G. W. THEONALD,

Professor of Obstetrics and Gynaecology,  
Bangkok.

Siam, May 22nd.

Sir,—In reference to the training of midwives and the education of medical students in midwifery I wish to suggest that the bigger midwifery schools should confine themselves to the training of medical students and graduates, and that the smaller midwifery training schools should receive the pupil midwives. This would leave a much wider scope for the better education of medical students and doctors. I do not suppose there is one of us who, when called out as a young graduate by a midwife for an emergency, did not regret at some time or other having had so little experience in his training school, both in ante-natal work and in deliveries. An abnormal case can be made normal during the ante-natal period: a normal case can be made abnormal during labour. The adoption of my suggestion would mean that the larger schools, finding themselves short of nursing staff, would have to employ a greater number of staff nurses. A staff nurse's post is equivalent to a post-certificate course to her. Thus, in effect, the larger schools would train medical students for their qualifying examination, and would provide doctors with post-graduate experience, and staff nurses with post-certificate experience. The smaller schools would train pupil midwives for their certificate examination.—I am, etc.,

Middlesbrough, June 11th.

G. H. GIFFEN DUNDAS.

#### PUERPERAL SEPSIS.

Sir,—It is the universal experience that many a Sairey Gamp, with no knowledge of nail-brush or lysol, working under the least favourable surroundings, has yet been able to show a spotless record. I myself can think of more than one such whose cases "never go wrong." We know, too, that it is common for difficult cases, attended by trauma, ending even in manual removal of the placenta, conducted in the most unsuitable surroundings, still to be followed by an uneventful convalescence.

On the other hand Mr. Burt-White, in his most interesting and, to my mind, important paper (*British*

*Medical Journal*, June 9th, p. 974), describes normal cases, under skilled modern supervision, that have had morbid puerperin, whilst Dr. James Young (p. 967) is so impressed by the danger of grouping parturient women within four walls that he urges that no maternity home should be without its isolation block.

These facts taken together seem to show, as Dr. Young himself suggests, that her own home is the safest place in which a woman may be confined, unless, perhaps, some exceptional difficulty is anticipated. If fever should occur the isolation difficulty does not arise, while if surgical intervention should become necessary she can be moved to a hospital or nursing home as easily as from a maternity home.

In a speech the other day the Minister of Health proposed, in addition to an increased number of maternity homes, an "improved" training of midwives. If by this he meant that he hoped that in future all pupil midwives would be taught to make only rectal (instead of vaginal) examinations in normal cases, I think few will disagree. But if it is proposed to add to their intellectual burden, then the results will certainly be disappointing in more ways than one.

Another not unimportant point arising out of Mr. Burt-White's paper is relative to the position of the practising midwife. At present there is a tendency at least to hint that a morbid puerperin is the result of some failure in her aseptic technique: in some instances she is made to feel that she is sitting on the edge of a precipice over which the first "temperature" may push her. It is to be hoped that one result of Mr. Burt-White's observations will be general recognition that however skilful, however careful, and however conscientious a midwife may be, untoward complications may appear, just as they do in surgical and medical practice, and that, when they do, she needs sympathy and help rather than blame. Moreover, if an investigation is conducted in the spirit of helpfulness, she will be much more ready to assist than if she feels that any evidence she may give is likely to be used to her own disadvantage.—I am, etc.,

Sydenham, S.E., June 13th.

W. M. PENNY.

#### THE TREATMENT OF MALIGNANT DISEASE BY COLLOIDAL LEAD.

Sir,—I cannot help thinking that Dr. Wyard has been ill advised to invite me to demonstrate further and completely the futility of his work and report, which reflects not only on himself, but inevitably also on the institution with which he is connected, for he states that the so-called investigation was a concerted effort in the Cancer Hospital. However, as he is unwilling to accept my "ex cathedra statement," which it was to his advantage to do, I shall take the trouble, which I would rather have been spared, of exposing the full extent of his errors in respect of the method of preparation of his so-called "colloidal lead," of which he says "I... affirm that they are the same as those used in Liverpool." From Dr. Wyard's account of his various methods the following points emerge.

1. Dr. Wyard's preparation was made by sparking... in a medium of distilled water. Afterwards he added the gelatin and electrolytes. We spark in a medium containing the gelatin and electrolytes. So far as one can say, without wasting the time necessary to investigate something which would be valueless to our work, a heavy, direct current such as that which appears to have been used would produce in distilled water lead hydroxide and large particles of metallic lead; there would certainly be very little colloidal suspension of lead. It is of primary importance to spark in the medium containing gelatin. In this respect, therefore, the method employed at the London Cancer Hospital is diametrically opposed to our own.

2. Dr. Wyard used isoelectric gelatin in some of his preparations. This is acid, and would, therefore, lead to the formation of lead ion ( $Pb^{++}$ ), the very thing the method is designed to avoid.

3. The preparation used by Dr. Wyard at the London Cancer Hospital does not appear to have been centrifuged; consequently it would contain large particles of lead—particles large enough to block capillaries—especially when made as described.

4. There is no mention by Dr. Wyard of any examination to discover whether lead ion were present in the material used. Undoubtedly the preparation would contain large quantities

of lead ion, which is toxic, and but little lead in colloidal form.

5. Dr. Wyard admits the addition of a reducing agent—presumably sodium hydrosulphite. Professor Dilling found this reducing agent caused the preparation to have a special toxicity, and, therefore, it was not used by us.

6. Animal investigations as to the toxicological and choriotropic properties of Dr. Wyard's preparations were not conducted. As to the toxicological effects, Dr. Wyard's comments with reference to my colleague Professor Dilling make it appear that he has neither the conscience to care, nor the ability to appreciate, Professor Dilling's gently conveyed rebuke to the effect that the sacrifice of a number of human lives is deplorable when information might have been gained, as Professor Dilling gained it, at the expense of two rabbits.

7. With regard to the question of "shot"—this word means, to a sportsman at any rate, shot used for shooting. Dr. Wyard states that he used "specially prepared lead 'shot.'" This is an *ex cathedra* statement, and, therefore, I am told by Dr. Wyard himself, is of no value. If I were further interested, but I am not, I should require him to go into details, and inform me of the maker. I had this in mind when I wrote my letter, but I did not think that even Dr. Wyard would be so foolish as to go to so much trouble when he could have obtained at once what we have always used—namely, "granulated lead," which is pure, and offers a larger surface than shot. To make sure, I telephoned to the manager of a large chemical firm, and was informed that, if asked for *lead shot* he would always supply the commercial article used for sporting purposes, and, if asked for *pure lead*, he would send "granulated lead." Even in this matter Dr. Wyard has missed the point. It is, I agree, well known that "commercial preparations of lead contain a small percentage of arsenic" as an impurity, but it does not appear to be equally well known, even by Dr. Wyard, that arsenic is added to the alloy of antimony and lead from which shot are made. In whatever way Dr. Wyard proposes to get out of this difficulty—and I hope he will not try to extricate himself—the fact will remain that alternatively he misled his readers by using the word "shot" without qualification or even inverted commas, and he must, therefore, excuse my scepticism regarding the explanation he now gives.

8. Lastly, since Dr. Wyard has not received any colloidal lead from us, and we have always used only that made here in the laboratories of my colleague Professor W. C. M. Lewis, the assertion of Dr. Wyard that most of his "doses were obtained from the source which was, and I believe is, supplying Professor Blair Bell himself," is simply untrue. I suppose Dr. Wyard has inferred that we have used choriotropic supplied commercially by the British Colloidal Co. This is not so. We have advised this company regarding the manufacture of this preparation, but have done no more than test it ourselves.

I hope I have now finished with an analysis of Dr. Wyard's methods, and that he will not encourage me further to waste time I can ill afford. I have felt it necessary for once to demonstrate clearly that when I make an *ex cathedra* statement it is at least wise to suspect that there may be some foundation for it. In this case there were, apparently, six or seven foundations, all supplied by Dr. Wyard himself.

Mr. Duncan Fitzwilliams and I myself have demonstrated the absurdity of the clinical investigations conducted at the London Cancer Hospital.

If my remarks have been strongly worded no one has regretted the necessity of forcible comment more than I. I have felt, however, that if I allowed to pass unnoticed, or to pass with gentle irony, such a report as that of the Cancer Hospital, our work might stand condemned by default; for Dr. Wyard's conclusion—a conclusion endorsed, I suppose, by his colleagues at the London Cancer Hospital—of the effect of lead on malignant disease, based on what I judged to be an almost unparalleled example of unsound work, was very definite and unqualified. Many who read such a paper, and were not conversant with the details involved, would naturally jump to the conclusion that the matter was therein settled. I sincerely hope that we may be spared such baseless and valueless criticism in the future.

Mr. Fitzwilliams has very adequately expressed what must have been the opinion concerning this report of those who have knowledge of the methods, of the disappointments and difficulties associated with it, and of the encouragement that is vouchsafed to us from time to time; and Mr. Fitzwilliams has, curiously enough, independently made a statement similar to that uttered by Dr. William Mayo in the early days of our work—namely,

that to treat very advanced cases of cancer is tantamount to expecting miracles, not cures in the usual sense of the word.

I am glad to know, from the evidence received from British, colonial, and foreign clinics, that the prophecy of my friend Professor Carter Wood has not been entirely fulfilled. When he saw the endless trouble and thought expended on each case in Liverpool, he assumed me that no one else would get results comparable with our own; and there was much in what he said, for to-day, with our numerous patients, we find it difficult to bestow the same personal care on each, yet we strive to do so. Still, it is evident there was much truth in this prophecy, and with Mr. Duncan Fitzwilliams I feel that at the beginning of such a tremendously difficult problem the results obtained will depend largely on the personality and sympathetic understanding of the investigator. Is it not true, indeed, that in the results of even well-established mechanical procedures, such as thyroidectomy, everything depends on the individual operator? I have in mind the work of that master-surgeon Crile, with his twenty thyroidectomies in a morning; his 10- to 15-minute, yet perfect, operations, and his mortality rate of 0.7 per cent. So with antisepsis and asepsis in the early Listerian period—as the kind of man, so the result.

It is only with patient, laborious work, and much stumbling and confusion on the way that the chemotherapeutical method—the ideal chemotherapeutical method—for the treatment of cancer will reach some degree of fool-proof certainty; it will never be infallible. We know no preparation of lead in use so far—and I suppose we ourselves have tried about one hundred—that approximates to the ideal. Thus with our lead-selenium preparations we have used stable, non-toxic materials made under Professor W. C. M. Lewis's direction. These were found to be no better than other preparations tried in regard to choriotropic and neoplasitropic properties; so for the present they have been put on one side. This is what Professor Dilling stated in his letter. We are none the less very glad to hear of the good results that have attended the use of a lead-selenium material in the hands of Dr. A. T. Todd. He may be using better preparations than those we have employed. So with the lead iodide of the British Drug Houses Company, which Mr. Patterson originally made on my instructions when he was working for us in Liverpool.

It is, however, to be remembered, as I have previously stated, that every lead preparation appears to have some effect, and in certain cases can arrest the growth of malignant disease with the disappearance of pain. The point is that no preparation of lead yet employed is so good that we can afford to hesitate in our search for something better, even at the cost of good statistics, which for the present are of little value in enabling us to assess the estimate that will be placed on this method of treatment in the future.

To have made a start is something; now—to emphasize Mr. Fitzwilliams's remark—we want the help of everyone who has the facilities, and will go to work in the right spirit and in the right way. We are not so egotistical and stupid as to think that we alone are capable of developing the ideal preparation, although, of course, we should like to finish what we have begun and have so widely explored. Nevertheless, as some already know, we desire to enlist as colleagues all who wish to work on the lines we have sought to establish, and to help, as we have in the past by any means in our power. Life is short, the problem vast, and time is pressing.—I am, etc.,

Liverpool, June 18th.

W. BLAIR BELL.

SIR,—In his letter, which you publish in your last issue, Mr. Fitzwilliams makes the egregious blunder of assuming that the duration of life after the commencement of treatment is identical with the duration of treatment. It is obvious that this is not necessarily the case. In my report, to which he refers, "duration of treatment" always means the interval between the first and last injection of colloidal lead, and has no relationship whatever with the duration of life.—I am, etc.,

London, S.W., June 18th.

STANLEY WYARD.

## SEA-SICKNESS.

SIR,—I noticed with interest Mr. R. H. Paramore's letter (June 2nd, p. 959), in which he agrees with Dr. Bennett in discounting the "labyrinthine" theory of sea-sickness, and centring the blame on liver functions.

Last February I took a voyage as temporary ship surgeon on the *Maunia* to Halifax and New York. I was sea-sick for three or four days, and took notes of my own symptoms. After my sea-sickness had gone the rest of the voyage was most exhilarating, and I returned feeling much fitter. I came to the conclusion that this condition is due to "waves of pressure" in the cerebro-spinal fluid, set up by the motion of the ship. These "waves of pressure," transmitted to the brain by the cerebro-spinal fluid, upset the normal function of the brain centres to such an extent in certain people that the brain inhibits the blood supply to the abdominal viscera, and thus checks seriously the general metabolism, until it reinstates itself in its new environment. The stomach then has no other course of action than to expel its contents, and other signs of disturbed metabolism appear, such as acidosis.

With regard to treating the symptoms it is generally agreed that lying on the back, warmth, fresh air, and the administration of glucose are excellent. The relief of symptoms which follows lying on the back supports my theory of waves of pressure in the cerebro-spinal fluid, for in that position the head and spinal column are kept most nearly at rest. As soon as the erect posture is assumed, particularly with a tall person, the swaying of the long vertical axis must cause waves of pressure in the cerebro-spinal fluid, both laterally and vertically. The chief desire of the patient then is to get the head down flat on the ground and to let it remain there; vaso-constriction of the abdominal blood supply is thus alleviated at once. After a few days the brain becomes educated to deal with its new environment and is not upset by the waves of pressure; it thus ceases the inhibition of the normal blood supply to the abdominal viscera. If sea-sickness was caused by "hepatic disturbance due to a diminution of blood flow through the liver, occasioned by the successive sudden falls of intra-abdominal pressure," as suggested by Mr. Paramore, it is difficult to understand how sea-sickness can be overcome in a few days, since the abdomen is not a subject for education, whereas the brain is.

When sea-sickness is considered from the broad aspect of its meaning it will be seen that it occurs for a purpose—namely, education to a new environment. When the land-liver goes to sea there is such a complete change in his whole environment that Nature decides that he must be put into bodily order for the struggle for existence. An ordinary attack of sea-sickness cleanses the stomach and mouth, and the abdominal contents generally; at the same time a general tightening up and improvement of the abdominal muscles results. As soon as this end is attained the patient is able to start on moderate meals, and to increase them quickly; he soon puts on weight and feels extremely well.

Sea-sickness, like pregnancy vomiting, is present with us for a purpose, and always will be with us. Alleviate it we can, but prevent it—never.—I am, etc.,

Southampton, June 8th.

W. A. ELLIOTT, M.B., B.S.

SIR,—Your correspondents on the subject of sea-sickness are evidently unaware of the endolymph theory, which was explained in my book on the subject, published so long ago as 1907. It was demonstrated there, I think beyond dispute, that sea-sickness is due to irritation of the endings of the vestibular branch of the auditory nerve by the endolymph undergoing unusual movement, and that prevention and cure depended upon the counteracting of this irritation, which was best obtained by large doses of bromide of ammonium.

Confusion is caused by the failure to recognize that true sea-sickness is a distinct entity due to the anatomical arrangement of the inner ear, and that it is quite distinct from "sickness at sea" due to the digestive and not the nervous system.—I am, etc.,

Bath, June 14th.

H. NORMAN BARNETT.

## IMMUNITY FOLLOWING HERPES.

SIR,—In view of the recent correspondence on this subject from Dr. Parkes Weber (May 19th, p. 875) and Dr. James Taylor (May 26th, p. 920), I venture to record the notes of three cases of apparently genuine recurrences of herpes zoster.

I saw a patient in April with severe herpes ophthalmicus and, to my surprise, she stated that this was her third attack of shingles. A few days later I saw her next-door neighbour, who inquired after her, and expressed deep sympathy as she had had three attacks herself. The same day I met a third lady who knew both of the others, and was astonished to hear that she herself had twice suffered from the same complaint.

This coincidence seemed to merit further investigation, and I obtained the following details.

*Case 1.*—In 1877, when 20 years of age, the patient had her first attack of shingles—apparently true zona on the left side. In 1897, when aged 40, she had a second attack, which affected the left shoulder and arm. In 1928, at the age of 71, she had severe herpes ophthalmicus, on the right. She was seen by a doctor on each occasion, and has no recollection of having had chicken-pox.

*Case 2.*—This patient, in 1883, when 36 years old, had a very painful eruption round the waist on the left side. She saw no doctor, but the diagnosis was subsequently made by him on hearing her story. In 1902, when 55 years of age, she had a more severe attack at the back of the neck and shoulder—side unknown, but seen by her doctor. In 1922, when 75 years of age, she had a third attack, which affected the back and waist on the left side. The attack was a severe one; and was seen by her doctor. She attributes the attacks to severe shocks, and has no recollection of chicken-pox.

*Case 3.*—This patient had her first attack, which affected the left side of the trunk, in 1894, when she was 39 years of age. In 1911, when she was 56, she had a more severe attack, again left-sided. She was seen by a doctor on both occasions, and has had chicken-pox.

It is clearly impossible to confirm these statements; but I feel that they are in all probability genuine recurrences. The interval in each case of a period of fifteen to twenty years seems of interest; might it be considered the limit of a period of immunity?—I am, etc.,

Cambridge, June 6th.

H. E. NOURSE, M.B., B.Ch.

## A PLEA FOR THE OPERATION OF LITHOLAPAXY.

SIR,—For the past three years I have witnessed a number of operations for stone in the urinary bladder performed in various London and provincial general hospitals and infirmaries; the operation was invariably removal of the calculus by the cutting method of "suprapubic cystotomy," and in all cases the stone was small and the bladder was clean.

Experience forces me to conclude that the operations were unjustified in that they involved an unnecessary cutting of the bladder wall, resulting in the patient's detention in hospital for many weeks and, at the best, in his being discharged with the bladder adherent to the anterior abdominal wall—surely a serious disability. I do not think it can be contended that, in the circumstances, the urinary organ after such an operation is quite as good as formerly. This is the argument from the patient's point of view, but the expense to the State in after-treatment and hospitalization for many weeks is very considerable as compared with what it would be were the operation of litholapaxy to come into general vogue.

Up to the latter part of last century perineal lithotomy was universal in India for the removal of bladder calculus until Bigelow introduced the operation of litholapaxy, consisting of the crushing of the calculus *in situ* and the evacuation of the fragments through a cannula at the same time. Since then this procedure has entirely displaced the cutting operation. I am safe in saying that if a surgeon proposed to an Indian to remove his stone by cutting he would not get the work to do—and the Indian would be right in his decision. Public opinion in India has been formed as the result of a great mass of experience; and, therefore, arguments which endeavour to prove that the cutting operation, as generally practised in this country, is as good as or superior to the crushing operation cannot be sustained. I can remember only a few instances of

calculi so large that they could not be removed by the operation of litholapaxy.

When I was civil surgeon of Hyderabad, Sind—at a hospital famous in India for stone, where as many as five to seven hundred stone operations have been performed per annum—it was no uncommon event during the "stone season" to have six or eight operations in one day. All would be dealt with by litholapaxy during the morning, in addition to the usual work. The patients were not admitted to hospital; their operations were carried out in a special theatre, and lasted from ten minutes upwards, depending on the size and hardness of the stone. The patients were then removed to the hospital verandah till the effects of the anaesthetic had passed off, after which they stayed the night at the adjacent rest house. Next morning they were usually able to report fit and return to their homes, undertaking long journeys by road or train. Their bladders had suffered in no way, as shown by absence of blood at time of operation and their well-being afterwards. From the point of view of the patient, the lesser mortality, and the minimum of expense for after-treatment, it cannot be gainsaid that litholapaxy for bladder calculus is immeasurably the superior operation. Why is it, then, that in this country litholapaxy is practically abandoned by general surgeons as the operation for vesical calculus? Can it be that the teachers at the British medical schools have not the experience and the data at their disposal to warrant their recommending the adoption of treatment by this method? In unpractised hands the operation of litholapaxy is certainly most dangerous, as it requires much experience to obtain the necessary "tactus cruditus."

It is not sufficient excuse for the general surgeon to continue to practise the inferior operation of suprapubic lithotomy by saying that he gets so few opportunities that he feels quite unequal to the task of performing litholapaxy with satisfaction to himself or safety to his patients. If he is to continue to operate for vesical calculus he should, in justice to his patients, take a two months' cold weather trip to India, where he would be able to observe experts at work, who would gladly instruct him in the art and give him opportunities for practising the technique, in the same way as the American ophthalmic surgeon visits India to perfect his technique in the operation for cataract.—I am, etc.,

L. P. STEPHEN, M.A., M.B., F.R.C.S. Ed.,  
Grimsby, May 18th.      Lieut.-Colonel, I.M.S. (ret.)

#### INJECTION TREATMENT OF VARICOSE VEINS.

SIR,—Dr. Borchers's letters are always interesting, but some of his statements are rather startling. If, as he says, all varicose veins are of syphilitic origin then every family must suffer from the lueic taint, as it is doubtful if a family ever existed where one member has not at some time suffered from varicosity either of the limbs or anal canal (piles). I cannot agree with him that intravenous injections of arsenical compounds cure varicose veins. During the past fifteen years I have given over ten thousand of the latter, chiefly to women (at the London Lock Hospital), whose arm veins are occasionally so small as to be almost imperceptible, and the injection has then to be given elsewhere, usually in a varicose vein. I did not observe that the varicosity disappeared following the injection of the arsenical compound. The possible explanation of Dr. Borchers's apparent success may be as follows.

The calibre of veins is regulated by the smooth muscle in their walls. This muscle is controlled by the sympathetic, and it is by means of the latter that the veins dilate or constrict. Excitation of the sympathetic leads to a diminution in the calibre of the veins. It was first pointed out to me by Professor Sicard (originator of the sodium salicylate sclerosing method) and Dr. Gaugier at the Necker Hospital, Paris, that simple insertion of the needle into the vein, even without injection, very often causes a remarkable constriction of the vein, the puncture acting as an excitator of the sympathetic. This constriction may last a considerable time, and as Dr. Borchers states that he bandages the limb immediately after injection and elevates it for fourteen days if ulcer exists, it is only to be expected that considerable improvement will result,

due to rest and compression, and not to the arsenical compounds. If he did not bandage and rest the limb immediately after injection he would see that vaso-constriction would soon give place to vaso-dilatation and the former varicose condition reassert itself.

Dr. Borchers speaks of the sclerosing method of treatment as one of "embolic injections." This is a grossly misleading description. The essential of embolism is that the clot must be loose; an embolus is a clot that has been "transported" by the blood stream. The most remarkable characteristic of the clot produced by sclerosing injections is the tenacity of its adherence to the vessel walls; it is almost impossible to pull it away from the latter. Embolism only occurs when the clot is infected; if suitable care in selecting cases is exercised and the injection given with correct technique and aseptic precautions, complete obliteration of the varicose veins will result with perfect safety, and embolism will not occur. Professor Sicard and Drs. Gaugier and Forestier stated recently at the Royal Society of Medicine that in over 300,000 injections given at the Necker Hospital, Paris, not a single case of embolism resulted. It is only in recent years that I have interested myself in treatment of varicose veins of the limb, but I have employed sclerosing injection in selected cases for piles during fifteen years and have not had a single case of embolism.

Intravenous arsenical injections occasionally cause anaphylaxis, but I think Dr. Borchers will agree that it would be misleading on that account to refer to the treatment as one of "anaphylactic injections."—I am, etc.,

P. KENNEDY MURPHY, M.A., M.D.

London, W.C., June 3rd.

SIR,—In the last paragraph of Dr. Borchers's letter in your issue of June 2nd (p. 960) he uses a term which is most puzzling—"embolic injections." Would Dr. Borchers please give his definition of the word embolus? If he is employing it in the sense generally given it in pathology then I submit that in this instance it is a misnomer and very misleading. No substance now in use for the injection of varicose veins ever produces emboli. It was the use of such substances as tinct. ferri perchlor., liq. iodotau., etc., that for seventy-five years (to within the last ten or twelve years) rendered these injections so dangerous. Even then these drugs did not cause emboli, but the soft, friable clot formed by them, together with infection, often caused fatal emboli.

Dr. Borchers's term would seem to be most unfortunate, as it was, and still is, in a measure, the bugbear not only of the general public, but also of some members of the profession at the present day. This fear of embolus (now proved to be more theoretical than real) all workers on the subject now agree to be groundless with modern methods in use, but I would suggest that there is possibly more chance of embolic formation with arsenical injections (Gougerot) than with the use of any of the other substances now employed, and this apart from other obvious objections to the method used by Dr. Borchers. I do not follow him when he says that these "embolic injections" should "throw the burden on to the deeper veins." In what way does his arsenical injection differ in its action and how does he prevent the deeper veins from being affected, as he affirms is the case with the use of "embolic injections"? Is the vein obliterated or not after this injection? If it is, in what way does it differ from veins blocked by other drugs? How are the deeper veins not likewise affected by his injection?

I venture to suggest that if Dr. Borchers were to employ the drugs in use here and on the Continent he would get just as good results as with the arsenical injections, for if he will consult Sicard's articles he will see that this authority ascribed the blocking of the veins to the sodium content of arsenical preparations and not at all to the arsenic, nor to its curative effect on the element syphilis, should it exist. The veins were blocked (where disease and varicose conditions were absent) at the site of the injections, and this seems to be all that is necessary for the cure of this prevalent and disabling infirmity. I submit that Dr. Borchers is curing his cases by sodium only, given in a very complicated way. I think he will have

great difficulty in convincing those conversant with the treatment of this complaint of the propriety of his method as compared with the simple methods now generally in use, especially as the cause of varix does not seem to be syphilis, at least in this country or on the Continent.—I am, etc.,

T. H. TREVELYAN BARNES, M.D., B.Sc.

London, S.W., June 3rd.

SIR,—I am afraid Dr. Borchers (June 2nd, p. 960) has not quoted my letter in your issue of March 13th quite correctly. If he will read my letter once more he will notice that I do not say that "the pressure of pregnancy" is a cause of varicose veins, but that I have made two distinct factors in "pregnancy and increased intravenous pressure from uterine causes." My reason for doing so is evident when one considers that the onset of varicose veins in pregnancy is most commonly observed long before there can be any question of increased intra-uterine pressure.

L. Gaugier has decided that the cause of the varices of pregnancy is of endocrine origin and that the pituitary gland is predominant in their causation. Meisen believes that they are probably the result of toxins acting on the walls of the veins, which toxins are caused by the temporarily subsided function of the ovaries. At any rate, modern evidence goes to show that in most cases some endocrine deficiency is the "fons et origo" of varicose veins, and I cannot disagree with Dr. Borchers if he says that syphilis is at the bottom of a certain number of cases, but I certainly do not feel that all are syphilitic in origin as he suggests.—I am, etc.,

London, W.1, June 7th.

RONALD THORNHILL.

#### NEPHRO-URETERAL ANASTOMOSIS AFTER COMPLETE AVULSION OF THE URETER.

SIR,—In the *Journal* of October 2nd, 1926 (p. 589), I reported a case where, following complete avulsion of the ureter and absence of any firm tissue with which to make a pelvi-ureteral anastomosis, the ureter was joined to the kidney by threading over an indwelling catheter.

The procedure was apparently a success, but I have just ascertained the subsequent history of the patient, which throws a different complexion on the matter. About a year after the operation a perinephric abscess developed, and ultimately the kidney had to be removed, when it was found that the lower part was hydronephrotic. The ureter had apparently successfully drained only the upper two calyces.

I consider it necessary to make this further report, which modifies considerably the value of such a procedure.—I am, etc.,

R. CAMPBELL BEGG,  
Senior Urological Surgeon, Wellington  
Hospital, N.Z.

Wellington, May 5th.

#### Obituary.

##### WILLIAM JAMES HOWARTH, C.B.E., M.D.,

Late Medical Officer of Health for the City of London.

WE have to announce with great regret that Dr. W. J. Howarth, for fifteen years medical officer of health for the City of London, died on June 15th, at Gerrard's Cross, in his sixtieth year, after many months of illness. His death removes a distinguished and much-respected guru from the world of preventive medicine.

William James Howarth was educated at Manchester Grammar School and Owens College, Manchester, and in 1890 took the diplomas of L.R.C.P. and S.Edin., and M.R.F.P.S.Glas. He graduated M.B. and Ch.B. at the Victoria University of Manchester in 1891, proceeding M.D. in 1893, and taking the D.P.H. in 1896. After obtaining his first qualification he became in turn house-surgeon to the Manchester Royal Infirmary and to the Loughborough General Hospital. In 1896 he was appointed medical officer of health for Bury, Lancs, and in 1898 medical officer of health for Derby, where he remained for ten years until his appointment as medical officer of

health and school medical officer for the county of Kent. In December, 1912, he was elected medical officer of health for the City of London on the retirement of Dr. William Collingridge. During the war he served with the rank of Major R.A.M.C.(T.) as honorary medical administrator of the Fishmongers' Hall Hospital for Officers, and as chief rationing officer under the London and Home Counties rationing scheme; for these services he was created C.B.E. in 1919. Dr. Howarth's intimate knowledge of meat inspection led to his appointment as chairman of the Meat Preservation Committee of the Food Investigation Board, and as a member of the Meat and Slaughter-houses Committee of the Ministry of Health; he was also a university nominee upon the Board of Management of the Low Temperature Research Station at Cambridge, and had served on the Ministry of Health's Insanitary Areas Subcommittee. In 1917 he was Milroy Lecturer before the Royal College of Physicians of London, taking as his subject "Meat inspection, with special reference to the developments of recent years." These varied and responsible activities, with the accumulated knowledge which such a succession of official positions of necessity implies, gave him a wide acquaintance with men and affairs, and his forceful character and statesmanlike outlook put him in the forefront of many of the advances in preventive medicine during recent times. He was for many years a zealous and highly esteemed member of council of the Society of Medical Officers of Health, holding office as president in 1921-22. In the latter year he presided also over a conference of medical officers of health during the congress of the Royal Institute of Public Health at Bournemouth.

Throughout his career Dr. Howarth was inspired by high ideals, always upholding the good name of his profession and the sanctity of English law as expressed in the various Public Health Acts and Regulations. He was opposed to sectionalization in medicine, and during the past ten years took an active part in the work of the British Medical Association, believing, and acting upon his belief, that its organization and aims made the Association particularly well fitted to bring into closer touch general practitioners and medical officers of health. He was for some time a valued member of the Public Health and Insurance Acts Committees, and served on a number of special committees and subcommittees at headquarters. He had been appointed president of the Section of Public Health for the Annual Meeting of the Association at Nottingham in 1926, but was compelled by sickness to resign that post shortly before the meeting.

After struggling against ill health for many months he at length handed in his resignation to the Corporation of the City of London, and in March last a resolution expressing deep appreciation of his valuable services as medical officer of health for the City was passed unanimously at the instance of the Sanitary Committee.

We are indebted to Dr. H. B. BRACKENBURY, Chairman of Council, British Medical Association, for the following tribute:

The long illness of Dr. W. J. Howarth has been a great loss to the British Medical Association, and his death has now made that loss irrecoverable. He was greatly interested in many of the Association's activities, and a strong and influential supporter of the Association's main policy in matters relating to public health and to the methods by which private practitioners of all kinds should take their part in the health work of local authorities. Even before he was president of the Society of Medical Officers of Health in 1921-22, his services had been sought as a member of certain special central committees dealing with matters such as these, and he afterwards consented to serve upon others. It was a great regret to him, as to all those who had hoped much from his counsels, that he found himself unable to take a more regular and energetic part in the work in which he was anxious to share. He held very strongly that the real solution of many health problems would be found in the extension of a national health insurance scheme to the dependants of insured persons, thus enabling much of the "clinic" work of local authorities to be done away with; and that

meantime this clinic work could most profitably for all concerned be placed in the hands of private practitioners. He had a far-seeing mind, and many statesmanlike qualities; and his sanity of outlook and great experience of health problems were very valuable assets which the Association will sadly miss.

**A. MASON JONES, M.D., F.R.C.S.Ed.,**

Surgeon, Ear, Nose, and Throat Department, Cardiff Royal Infirmary.

We have to record with much regret the death of Dr. A. Mason Jones, one of the vice-presidents of the Section of Laryngology and Otology at the forthcoming Annual Meeting of the British Medical Association. Although he was the subject of a valvular heart affection from boyhood he had carried on his work with cheerfulness and spirit until three months ago, when auricular fibrillation supervened, and he died on June 11th.

Archibald Mason Jones was a native of Glamorgan, having been born at Skewen, near Neath, in 1883, and received his medical education at Edinburgh University, graduating M.B., C.M. in 1909 and proceeding M.D. two years later. In 1920 he was admitted a Fellow of the Royal College of Surgeons of Edinburgh. After qualifying he was engaged in general practice for four or five years in South Wales, and thus gained an invaluable training and introduction to the special branch of work he took up later. During the war, though his disability prevented him from serving overseas, he held a commission in the R.A.M.C., and did excellent service in this country. When the war ended he took up the study of laryngology and otology, and became later successively house-surgeon and clinical assistant to the ear and throat department of the Cardiff Infirmary, to which he was appointed assistant surgeon in 1923. At the commencement of this year he was promoted surgeon, and became head of the department. His work was characterized by soundness and devotion, and his kindness made him popular with his patients. He had acted as demonstrator of anatomy at the Welsh National Medical School for some years, and was aural specialist to the Cardiff Education Authority, while his services brought him also into association with the Cardiff City Mental Hospital, the King Edward VII Welsh National Memorial Association, and the Maesteg and Morrison Hospitals. He was a loyal colleague, and all who came in contact with him mourn his passing when on the threshold of a promising career.

Mason Jones took an active interest in the affairs of the British Medical Association, having been joint secretary of the Cardiff Division for four years, deputy representative in 1926, and representative in 1927. He looked forward to the coming of the Association to the capital of his native Glamorgan, for which he cherished a warm affection, and it was a great grief to him, when laid aside, that he could no longer take his share in the work of preparation. He is survived by his widow and two children.

**J. A. MACDOUGALL, M.D., F.R.C.S.Ed.,**

Consulting Surgeon, Queen Victoria Memorial Hospital, Nice.

DR. JOHN AYMERS MACDOUGALL died on June 12th at Balerno, in Midlothian, where he had made his home in the years since his retirement. His death, at the age of 83, removes a link with some of the most notable figures in the medical life of Edinburgh in the last century.

Born in July, 1844, he was the son of Dr. George MacDougall, a medical practitioner in the Scottish border town of Galashiels, and received his early education at the High School of Edinburgh, proceeding, in 1861, to the University, where he commenced the study of medicine. Four years later he graduated M.D., along with his friends John Chiene, John Wyllie, and W. Allan Jamieson, of whom the two former came in due time to fill professorial chairs in their alma mater. In 1875 he was admitted F.R.C.S.Ed. Some reference should be made to the men who taught in the medical school in an interesting period of its history. The students of his year—of whom only eight survive of the sixty-three who graduated with him—

were fortunate in receiving their instruction from a remarkable group of men. John Goodsir, John Hughes Bennett, Sir Robert Christison, and Sir James Young Simpson, among others, occupied chairs in the Medical Faculty. In the Royal Infirmary James Syme and Thomas Laycock were clinical professors, while Patrick Heron Watson, Daniel Rutherford Haldane, and William Rutherford Sanders were members of the honorary staff of the hospital. John MacDougall, as a dresser, came into close touch with James Syme, for whom he retained throughout his life a profound admiration, and whose teaching and practice of surgery he closely followed in after years. In 1866 he became house-surgeon to James Spence, who had lately been appointed professor of systematic surgery. Joseph Lister during this period was working in Glasgow, and, although he did not publish until 1867 his epoch-making paper on his first series of cases of compound fracture treated by his new method based on the "germ theory" of Pasteur, rumours of the new learning had filtered through to Edinburgh from the medical school in the west.

Returning to his birthplace on the completion of his training, Dr. MacDougall settled in general practice, but after nine years of a busy life in Galashiels he crossed the border in 1875 to Carlisle and became surgeon to the Cumberland Infirmary, where he was able to develop his taste for surgery, in which he was intensely interested and highly efficient. In 1885, however, the state of his health led him to seek a less rigorous climate, and he accordingly removed to Cannes. For twenty-nine years he conducted an extensive practice as physician and surgeon there, his services being in great demand along the whole of the French Riviera. He was latterly consulting surgeon to the Queen Victoria Memorial Hospital, Nice, and surgeon to the Asile Française, Cannes. He retired from active work at the age of 70, in 1914.

A colleague writes: A large circle of friends, both within and without the profession, mourning his death, will retain the memory of a very lovable man. MacDougall was a born physician, and possessed in an exceptional degree the clinical instinct; he was an accurate observer, and his powers as a diagnostician were remarkable. He had the gift of establishing between his patients and himself a strong bond of sympathy and friendship. His friends were attracted by his high integrity, his great personal charm, his obvious sincerity, and the gentleness of his nature. With an excellent and accurate memory, his reminiscences of the Edinburgh Medical School of sixty years ago and more were always interesting and instructive. To the end of his life he kept himself abreast of progress in medicine and surgery, and just before his death had commenced to prepare for publication recollections of his former and revered teacher James Syme. The sympathy of many friends is with his widow and daughters in their bereavement.

DR. ROBERT JOHNSON PIRIE, who died suddenly on May 22nd at his residence, Murrayfield, Pittenweem, in his sixty-second year, received his medical education in the school of the Royal College of Surgeons of Edinburgh, and in 1889 obtained the diplomas L.R.C.P., L.R.C.S.Ed. and L.R.F.P.S.Glas. He then spent a period in study at Berlin, and soon afterwards commenced practice in Pittenweem, becoming, in the course of his thirty-five years' work there, one of the best-known practitioners in East Fife. He took a considerable interest in local affairs and in the work of his profession, and was a member of the Fife Branch of the British Medical Association. For some time past he had not been in good health, but had been able to carry on his practice with the assistance of one of his daughters, who is also a medical practitioner. Dr. Pirie is survived by his widow, two sons, and four daughters.

The death occurred on June 4th of Dr. VINCENT THEODORE CARRUTHERS, a well-known practitioner in Dundee; he was taken ill while swimming at the corporation baths, and died soon afterwards from heart failure. Born in 1880, he was sent to Tonbridge School, and

received his medical education at the University of Edinburgh, graduating M.B., Ch.B. in 1904 and proceeding M.D. in 1921. In 1908 he was admitted to the Fellowship of the Royal College of Surgeons of Edinburgh. After graduating he was for a time house-surgeon to Sir Montagu Cotterill in the Edinburgh Royal Infirmary, and was subsequently appointed to a commission in the R.A.M.C. During the war he served with various medical units in France, and after the armistice was attached to the Army of the Rhine. He was finally employed as surgical specialist to the Scottish Command, and retired from the army with the rank of major. He resided for some time in Derby, where he was obstetric physician to the Nightingale Institute, and later commenced practice in Dundee. He was a member of the British Medical Association, and the author of a number of contributions to various medical journals. He is survived by his widow and two daughters.

DR. FRANCIS W. SQUAIR of Cults, Aberdeenshire, died suddenly, on June 13th, whilst responding to the toast of his health at a dinner of the Fawcett Lodge of Freemasons at Seaham Harbour. He was educated at Aberdeen University, where he graduated M.B., Ch.B. in 1902. After practising at Seaham for a year or two he migrated to Greenock, but returned to Seaham in 1909. He held a commission as major R.A.M.C. during the war, and subsequently became attached to the R.A.F.M.S. with the rank of flight lieutenant (honorary squadron leader). He had also served as D.A.D.M.S. 51st (The Highland) Division, T.A., and as visiting medical attendant at the Greenock Infirmary and Dispensary. Dr. Squair, who was a member of the British Medical Association and a Fellow of the Royal Society of Medicine, had for some time suffered from indifferent health.

We regret to announce the death, in his 43rd year, of Dr. ROBERT ROGER of Muswellbrook, New South Wales, which occurred in a London nursing home on June 10th, only a month after he had arrived on a visit to England. He received his medical education at the University of Sydney, graduating M.B., Ch.M. in 1909, and, after practising at Scone and Murrumbidgee, settled down in 1915 at Muswellbrook, where he shared an extensive practice with two partners. Although of a retiring disposition he was well known to members of the medical profession throughout the northern district of New South Wales, and among them he was held in high esteem. Dr. Roger was a member of the New South Wales Branch of the British Medical Association. About a fortnight after his arrival in England he contracted influenza and later pneumonia, and empyema developed. He is survived by his widow, one son, and two daughters.

## The Services.

### DEATHS IN THE SERVICES.

Fleet Surgeon Charles Francis Newland, R.N.(ret.), died in Ceylon on April 14th, aged 76. He was educated at St. Mary's, took the M.R.C.S. in 1875 and the L.R.C.S. Ed. in 1876, entered the navy in 1877, and attained the rank of fleet surgeon in 1897. While serving as fleet surgeon on H.M.S. *Theseus* he took part in the punitive naval expedition to Benin, commanded by Rear-Admiral Rawson, C.B., in 1897, was present at the capture of Benin city on February 18th, 1897, and received the general African medal, with a clasp for Benin.

Colonel Henry Herriek, C.M.G., D.S.O., R.A.M.C.(ret.), died at Chisleton Camp, Wilts, on May 10th, aged 56. He was born on January 12th, 1872, the son of the late Rev. George Herriek of county Cork, was educated in the School of the Royal College of Surgeons, Ireland, and took the L.R.C.P. and S.I. in 1896. Entering the army as lieutenant on July 27th, 1898, he became colonel on June 3rd, 1923, and retired on June 3rd, 1927. He served in the South African war in 1901-2, receiving the Queen's medal, and in the war of 1914-18, when he was thrice mentioned in dispatches—in the *London Gazette* of June 22nd, 1915, May 29th, 1917, and December 30th, 1918, and received the D.S.O. in 1917 and the C.M.G. in 1919.

Lieut.-Colonel Edmund Ernest Parkes, R.A.M.C., died recently after an operation in the Station Hospital at Jubbulpore.

Central Provinces, India, aged 52. He was born on October 28th, 1875, and was educated at Trinity College, Dublin, where he graduated as B.A., M.B., B.Ch., and B.A.O. in 1899. Entering the army as lieutenant on January 29th, 1901, he became brevet lieutenant-colonel on January 25th, 1923, and got that rank substantively on March 31st, 1925. He served in the South African war in 1901-2, taking part in the operations in the Transvaal, Orange River Colony, and Cape Colony, and received the Queen's medal with five clasps, and also in the recent great war. At the time of his death he was in command of the Jubbulpore Station Hospital, in which he died.

## Universities and Colleges.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ORDINARY Council meeting was held on June 14th, when the President, Sir Berkeley Moynihan, Bt., was in the chair.

#### Fellowship.

It was reported that 115 candidates had presented themselves for the Fellowship examination, of whom 34 (including two women) were successful. The diploma of Fellowship was conferred upon the following candidates:

A. J. W. Ahern, F. G. Allan, J. C. Anderson, L. H. Ball, J. Brumwell, J. Carver, A. M. C. W. Flemming, J. Elwood, D. M. B. Evans, C. W. Flemming, Gairdner, J. Gray, W. A. Gray, P. Hack, E. Holmes, G. H. Howell, H. Jackson, J. A. James, J. G. J. James, L. C. Lancaster, L. E. Le Souef, A. C. MacLeod, Gladys H. Marchant, M. O. Nimatallah, D. W. C. Northfield, Constance M. Otaker, S. M. Power, B. G. Scholefield, J. H. Thompson, J. H. M. Walker.

The diploma of Fellowship was also conferred upon the following candidates, who had previously passed the examination and had now attained the required age of 25 years: J. Gore, R. L. Holt, F. T. Ridley.

#### Membership.

The diploma of M.R.C.S. was conferred upon the following candidates, who had passed the requisite examinations and complied with the by-laws:

D. W. Currie, Yotta Gimpelson, B. Natarajan, Margaret E. Peaker, Edith J. L. Smith, G. N. Unnithao, Elsie E. Wright.

#### Examiners.

The following examiners were appointed for the ensuing year:

*Dental Surgery (Surgical Section):* L. B. Rawling, H. S. Clogg, T. P. Legg, R. J. Howard, G. E. O. Williams, C. H. S. Frankau, J. Murray, E. R. Carlinar. *Anatomy and Physiology for the Fellowship:* Anatomy, F. G. Parsons, W. E. Lo Gros Clark, C. P. G. Wakeley, P. N. H. Odgers; Physiology, J. B. Leathes, H. E. Roaf, C. A. L. Evans, R. J. S. McDowall.

Under the Joint Examining Board:

*Elementary Biology:* T. W. Shore, J. P. Hill. *Anatomy:* J. B. Hame, W. Wright, R. B. Green. *Physiology:* G. A. Buckmaster, E. B. Verney. *Midwifery:* D. W. Roy, R. B. Whitehouse, C. White, T. B. Davies. *Diploma in Public Health:* Part I, R. T. Hewlett; Part II, C. W. Nutt. *Diploma in Tropical Medicine and Hygiene:* Pathology and Tropical Hygiene, W. P. MacArthur; Tropical Medicine and Surgery, P. H. Manson-Bahr. *Diploma in Ophthalmic Medicine and Surgery:* Part I, C. B. Goulden, H. W. Lyle; Part II, R. A. Greeves. *Diploma in Psychological Medicine:* F. L. Golla. *Diploma in Laryngology and Otology:* Part I, W. M. Morrison, N. Patterson; Part II, S. R. Scott.

Mr. E. B. Dowsett and Mr. A. T. Pitts were re-elected members of the Dental Section of the Board of Examiners in Dental Surgery.

#### Primary Fellowship.

At the recent primary examination for the Fellowship 160 candidates presented themselves, of whom 20 were approved and 140 rejected. The following were the successful candidates:

R. L. Almond, M. I. Ashmawi, M. Backwell, J. S. Batchelor, W. D. Bedford, H. S. Billeliff, J. D. H. Bird, D. A. S. Blair, H. A. Brittain, R. C. Brock, T. E. Cawthorne, H. L. Cleave, J. H. Cramsie, J. Dawson, D. N. Epstein, R. H. Fish, R. L. Flett, J. F. E. Gillam, A. G. Harrison, E. S. Harverson, H. P. Himsforth, M. B. Lavery, E. S. Leo, R. O. Lee, W. Leslie, A. C. Lysaght, R. G. Maliphant, A. J. Mason, M. V. Modi, H. S. Morton, A. R. Mowlem, J. H. Mulligan, G. H. Newns, C. W. Olsen, M. D. Patel, J. B. Peonybacker, P. N. Ray, J. G. Reid, A. H. Richardson, N. H. L. Ridley, M. C. Rous, A. Simpson-Smith, G. J. Sophian, V. Srinivasan, F. S. Tait, H. S. Thomas, T. F. Todd, C. K. Vartan, A. L. Webb, T. H. Wilson.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THE following have, after examination, been admitted as Fellows of Faculty: J. Craw, S. B. Trivedi, A. M. Young.

### LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD.

THE following awards of entrance scholarships and exhibitions have been made: *University College—Medical Scholarship*, £30 a year for three years, to G. Quist. *King's College—Warneford Medical Scholarship*, £20 a year each for four years, to J. F. Jarvis and J. C. Winteler; *Sanbrooke Scholarship in Medical Science*, £30 a year for three years, to G. B. Davis; *King's College Hospital Medical School; Scholarship in Science (£50) to H. Kirman.*

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

ON June 19th Mr. J. H. Whitley resigned the Speakership of the House of Commons and the House took farewell of him. On the following day Captain E. A. Fitzroy, member for Daventry, was elected Speaker. The other chief business of the House during the week was the Committee stage of the Rating and Valuation (Apportionment) Bill. The House of Lords read the Equal Franchise Bill a third time on June 18th.

### National Health Insurance Bill.

The House of Lords went into Committee on June 14th on the National Health Insurance Bill. The Chairman, Lord DONOVAN-MORE, remarked that there was only one amendment to the First Schedule. Lord ASKWITH moved that to the additional benefits allowed by this schedule there should be added "allowances in respect of dependants of insured persons in receipt of sickness or disablement." He said that 124 women's societies throughout the country had approved this proposal. Lord GAGE, for the Government, said that not only the Ministry, but the approved societies considered that the surpluses should be devoted principally to benefits in the nature of treatment. If the amendment were passed and adopted by the approved societies, little money would be left for dental and ophthalmic benefits. From 1911 to the present time no representations had been made to the Minister of Health that the approved societies favoured this proposal. The amendment was withdrawn and the bill was reported without amendment. It was set down for third reading on June 21st.

### Dogs Act (Amendment) Bill.

In Committee, on June 15th, the House of Commons considered the Dogs Act (Amendment) Bill, introduced by Mr. Briggs. On Clause 2 (delivery of stray dogs to the police) Mr. BAIGES moved new words which provided that the finder of a stray dog should return it to its owner or take it to the nearest police station. If the finder desired to keep the dog he must receive a certificate from the police and be under an obligation to keep it for not less than one month. Mr. Briggs added that the bill was an agreed one. Sir ROBERT GOWER supported the amendment, which was inserted. The bill was then reported and read a third time.

### Training of the Deaf and Dumb.

In the House of Lords, on June 18th, Lord CHAMBERWOOD called attention to the position in industry of the congenitally deaf and dumb and of those wholly or partially deafened in later life by disease or accidents. He also referred to the limitations of the present provision made for their training, and for securing employment for them, and asked the Government to set up an inter-Departmental Committee to inquire into the whole matter.

Lord GAGE said that before the Ministry of Health came into existence a great deal of work on behalf of the deaf was done by voluntary associations, whose work was still being continued. The Minister had no intention of interfering with that magnificent work. If they were to apply the analogy of the machinery set up to deal with the blind to all congenital afflictions the Ministry would have a great financial load put on it. The information at the Board of Education went to show that deaf children who had attended special schools provided by the Board up to the age of 16 were able to obtain and retain reasonably good and remunerative work. He could not make any promise that an inquiry would be undertaken, but he would bring the points raised in the debate before the Minister of Health.

### Storage of Poisonous Gases.

Sir LAMING WORTHINGTON-EVANS told Mr. Thurtle, on June 6th, that small quantities of phosgene gas and similar compounds were kept by the British Army for use in research and experimental work. On the same day Sir VIVIAN HENDERSON (Under Secretary of the Home Office) told Commander Kenworthy that no regulations were in force in the United Kingdom for preventing the storage of poisonous gases near large centres of population. The use made of phosgene and other poisonous gases in industrial processes necessitated the storage of these gases in the factories concerned. At Hamburg, where phosgene gas was accidentally released, the containers appeared to have been of much greater capacity and liable to far greater stress than the containers generally in use in this country. Inquiries by the Home Secretary had shown that the containers in use here had a wide margin of safety, and that the position generally was satisfactory. A committee of the Scientific and Industrial Research Department was inquiring into the storage of such gases, and the situation would have to be reviewed in the light of its findings. The supply of gas masks to the police would be considered, but hardly appeared necessary.

On June 11th, Mr. G. LOCKER-LAMPSON, in reply to Sir W. Davison, stated that the obligations assumed by the German Government under the Treaty of Versailles in respect to the manufacture and storage of chemicals utilizable as poison gas had been defined by agreement in subsequent correspondence between the ex-allied powers and that Government. The manu-

facture, storage, sale, import, and export of phosgene, intended for war purposes, was forbidden. The manufacture of phosgene intended for industrial purposes was confined to three factories, and the machinery for producing the gas in each of these factories was limited so as to fix the total maximum output at nine tons a day. No restriction was placed upon the export or storage of phosgene so produced for industrial purposes. The facts hitherto brought to light afforded no proof that the German Government had failed to ensure the observance of these conditions, and the British Government did not consider that any action on their part was required. If there was any suspicion of an infringement of the treaty the League of Nations was entitled to hold an inquiry.

### Treatment of Pensioners Patients.

On June 18th Major TRYON informed Mr. Duckworth that it was the duty of the proper medical officers of the Ministry of Pensions to prescribe whatever form of treatment they might consider necessary for ex-service pensioners suffering from chronic disabilities. In a case where no special treatment beyond attention from a general practitioner was required, the pensioner was advised to consult the practitioner whose services were available to him under the Health Insurance Act. This was the longstanding practice of the Ministry, and he would not be justified in requiring, as Mr. Duckworth suggested, the provision of hospital treatment in all cases.

Colonel STANLEY, replying to Mr. Johnston, on June 18th, said no instructions had been issued to local medical officers of the Ministry of Pensions urging the curtailment of treatment allowances paid in respect of ex-service men suffering from tuberculosis.

Mr. R. MORRISON asked why it seemed almost impossible for ex-service men to get treatment allowance except by going into a Ministry of Pensions hospital. Colonel STANLEY said that that depended entirely upon whether the treatment that the man was to undergo would prevent him from working. Lady ASTOR asked whether one of the real difficulties was that men who got treatment came out before their treatment was finished. Could not some way be found of guaranteeing that they should stay until they were discharged as practically cured? Colonel STANLEY said the Ministry had no power to keep a man if he did not wish to stay.

### Dr. Voronoff and Grafting Experiments.

Mr. BRIANT asked the Home Secretary, on June 14th, if a permit had been given to Dr. Voronoff to visit this country; if so, for what period it was available; and if such a permit would allow him to carry out experiments of the nature of grafting on human beings. Sir WILLIAM JOYNSON-HICKS replied that Dr. Voronoff was given leave to land in the United Kingdom on May 22nd, and no time limit was imposed. His object was to give certain lectures at Cambridge University and elsewhere, but no licence of any kind had been given him to experiment in this country. Mr. BRIANT asked the Home Secretary if Dr. Voronoff could make experiments without a licence. The British public were extremely anxious to know that he should not have an opportunity of conducting dangerous and disgusting operations, which included the transfer of the organs of propagation from an ape to a woman. Sir W. JOYNSON-HICKS: It is quite impossible that he should conduct any experiment involving vivisection or cutting operations on any animal without a licence, and that licence I have not granted and do not propose to grant. Dr. FERNANTZ asked if a human being was not an exception, and if he could not offer himself for experiment if he liked. Mr. RADFORD asked if it would be possible for some other licensed person to make an operation on an animal and to leave it to Dr. Voronoff to complete the experiment on a human being. Did the Home Secretary not think that it was a violation of everything that was decent in our constitution that this man should be allowed to conduct such experiments in this country? Sir W. JOYNSON-HICKS: No such experiments are conducted in this country at all, and the suggestion that it would be possible to have an operator who has a licence would not work, because I am most careful to inquire into the nature of the operations conducted under a licence.

### Bills.

The Representation of the People (University of Reading) Bill, which proposes to include Reading University in the combined English universities constituency, was passed through committee of the House of Commons, on June 15th, and read a third time.

The Solicitors Bill, to prevent persons struck off the rolls of solicitors from practising fraudulently, was read a second and a third time in the House of Commons on June 15th.

The Petroleum (Amendment) Bill was considered on the report stage by the House of Lords on June 11th. There was no reference during the discussion to lead tetra-ethyl. The bill was read a third time by the House of Lords on June 14th.

The Food and Drug (Adulteration) Bill, which is one of a number of consolidating measures being carried by the Ministry of Health, was read a second time in the House of Lords on June 11th.

State Grant in Aid of Medical Benefit.—Mr. CHAMBERLAIN told Mr. Smedley Crooke, on June 7th, that the State grant in aid of medical benefit to aged friendly society members was less than £1,000 in 1926 and was rapidly diminishing. It had to be distributed among 7,000 approved societies and branches, and the cost of distribution far exceeded the sum to be distributed. He had decided that continuance of the grant was not justified. The Consultative Council concurred.

**National Health Insurance Inspectors.**—Mr. CHAMBERLAIN announced, on June 7th, that he had decided to reconstitute the duties of men and women national health insurance inspectors on a common basis, retaining for the present separate seniority lists for men and women.

**Vaccination Statistics.**—Dr. Vernon Davies was informed by Mr. CHAMBERLAIN, on June 7th, that the report of the committee on vaccination had been received and would shortly be published as a command paper. Mr. Chamberlain stated that in 1926 the percentage of successful vaccinations to hithis in Newcastle-on-Tyne was 68; in Birmingham, including Perry Barr, 61; in Manchester, with Failsforth, 63; in Liverpool, with part of Sefton, 72; in the part of Sheffield within Sheffield Union, 57; in Bradford, with Clayton, Denholme, and Drighlington, 32; in Leeds, 60; in Warrington, 65; and in Darlington, 23.

**Voluntary Hospitals Commission.**—On June 8th Dr. LITTLE asked the Minister of Health his reasons for discharging the Voluntary Hospitals Commission; and if he would reconsider his decision, in view of the regret expressed by the Commissioners that they were disabled from implementing proposals to which they had devoted time and attention. Mr. CHAMBERLAIN answered that, as stated in paragraph 2 of the final report of the Voluntary Hospitals Commission, the reasons, with which the Commission concurred, for which the work of the Commission had been concluded were, first, that there was no prospect of an Exchequer grant in aid of capital expenditure by voluntary hospitals on the provision of new beds; and, secondly, that in the absence of such a grant it would not be justifiable to make further calls on the time and services of the members of the Commission collectively. He was not aware of any ground for reopening the matter.

**Decisions of the Pensions Appeal Tribunal.**—Lieut.-Colonel G. F. STANLEY, answering Lieut.-Colonel Thom, on June 12th, said that the decision of the Pensions Appeal Tribunal was by statute final, and the provisions of the War Pensions Act, 1919, did not admit of a rehearing by the tribunal of cases once decided. The Ministry had been enabled, in exceptional cases where fresh material evidence was produced, to reconsider a claim. If such evidence was produced in a case where an appeal had been made and had failed, it was the practice to consult the president of the tribunal informally before making any recommendation for a grant, in order that no point in favour of the claimant might be overlooked. Lieut.-Colonel Stanley said he agreed on the desirability of making final awards in all cases as early as possible, but it would not be justifiable, nor in the interests of pensioners, that such awards should be made without proper medical consideration of the individual cases. Warning about the operation of the statutory time limit had been given by the exhibition of posters in all post offices, and in all the local offices of the Ministry. The time limit expired seven years after discharge from service, and in any event not later than August 31st next.

**Workmen's Compensation for Silicosis.**—On June 12th Sir W. JOYNSON-HICKS told Mr. Rennie Smith that the Departmental Committee on Workmen's Compensation for Silicosis was directed, under its terms of reference, to advise on any proposals which the Home Secretary might refer to it for schemes of compensation in industries liable to the disease. The committee was inquiring into a scheme for the pottery industry, and he had asked it, as soon as that inquiry was completed, to advise on a scheme for the coal-mining industry. There was a question coming on soon afterwards with regard to silicosis in sandstone quarries. If the report of the committee was sufficient, he had powers already to make a scheme under the Workmen's Compensation Act. He could not say, without notice, whether the committee would inquire into silicosis among the workers in the brick-making industry.

**Cost of Treatment of Tuberculosis.**—On June 19th Captain MARGESSOR told Mr. Oliver that the total expenditure in England and Wales on the carrying out of the approved schemes for the treatment of tuberculosis during each of the last four years ended March 31st, for which figures were at present available, excluding capital expenditure, was £2,884,062, in 1924; £3,054,600, in 1925; £3,157,694, in 1926; and £3,294,991, in 1927.

**Tuberculosis and Service Conditions.**—Mr. BALDWIN told Dr. Vernon Davies, on June 13th, that a committee composed of medical members of the service departments was considering the attributability of pulmonary tuberculosis in the defence forces to the conditions of service, but at that date no recommendations on the subject had been received.

**Sanatorium Treatment of Tuberculous Persons and Vaccination.**—Sir KINGSLEY WOOD, on June 11th, told Mr. T. Williams that he was not aware of cases in which sufferers from tuberculosis had been precluded from receiving sanatorium treatment unless they consented to be vaccinated, and he had not sanctioned regulations to that effect. Mr. WILLIAMS asked if the right hon. gentleman was aware that in the West Riding of Yorkshire it was said that some regulation existed which precluded a person suffering from tuberculosis from entering a sanatorium unless he was vaccinated, and if he would make inquiries. Sir KINGSLEY said he would require far more definite information before acting. Mr. WILLIAMS asked if he was to understand that the Ministry was not responsible for a regulation of that kind. Sir KINGSLEY WOOD: I have just said so.

**Administration of the Sale of Food and Drugs Acts.**—On June 7th Mr. Chamberlain promised to consider a suggestion from Dr. Vernon Davies that he should draw the attention of all local authorities to the fact that medical officers of health and sanitary inspectors were entitled to procure samples under the Sale of Food and Drugs Acts, and to prosecute offenders, although these officers might not be the usual authorities for administering these Acts in their areas.

**Foot-and-Mouth Disease.**—On June 11th Mr. GUINNESS informed Sir R. THOMAS that for some years it had been known that the serum of animals which had recovered from foot-and-mouth disease when injected into susceptible animals would protect them for a few days against the disease. The Foot-and-Mouth Disease Research Committee and scientists on the Continent were actively trying to discover a practical method of giving animals a lasting immunity from the disease, but the task presented very great difficulties.

**Hospital Officers in the Prison Service.**—Sir WILLIAM JOYNSON-HICKS stated that there are 130 men hospital officers and 10 women hospital officers in the prison service; of the men, 38 are registered by the General Nursing Council as nurses, 9 as mental nurses, and 6 are registered under both heads; none of the women are registered. There are, however, 33 fully trained women nurses employed in the prison service, all of whom are State registered, 31 being on the general register and 2 on the register of mental nurses.

**Medical Inspection of Casuals.**—On June 18th Mr. CHAMBERLAIN told Mr. Shepherd that he was afraid that the varying conditions of staff and accommodation in the different casual wards, and the late hour of arrival of some casuals, made it impracticable to arrange that boards of guardians should be instructed to have the medical inspection of casuals carried out in the evening, before risk of infection of clothes and bedding.

**Maternal Mortality in Childbirth.**—On June 18th Mr. CHAMBERLAIN told Mr. Tasker that no complete statistics were available on the percentage of deaths of mothers in childbirth where doctors attended the birth of children with uncertificated midwives in attendance. Asked the percentage of deaths of mothers in childbirth when attended by certificated midwives only, Mr. Chamberlain referred Mr. Tasker to page 42 of the recent report issued by his department on the "Protection of Motherhood," which summarized an analysis of the midwifery work of the Queen Victoria Jubilee Institute over a period of years.

**Use of Croton Oil in Mental Institutions.**—Mr. CHARLETON asked the Minister of Health, on June 14th, whether the recommendations made by the Royal Commission on Lunacy and Mental Disorder, 1926, for the control of the use of croton oil, whether for medicinal or punitive purposes, in mental institutions, were receiving attention; and whether he proposed to take any administrative or other action. Mr. CHAMBERLAIN answered that the recommendation of the Royal Commission had received consideration, but the report did not support the suggestion in the question that the drug was used for punitive purposes. The administration of drugs of this character was the subject of frequent consultation between the Medical Commissioners of the Board of Control and the medical officers of mental hospitals, and he was advised that no further action was at present necessary.

**Dispensers in the R.A.M.C.**—On June 12th Sir L. WORTHINGTON-EVANS told Sir Wilfred Sugden that provision for the enlistment of dispensers was made in the establishments of field ambulances and general hospitals of the Territorial Army. Sir W. SUGDEN asked if these pharmacists were invited or desired to serve in the Royal Army Medical Corps. Sir L. WORTHINGTON-EVANS replied that they certainly would be eligible, if they desired to enlist. Replying to a further question by Sir W. Sugden, Sir L. WORTHINGTON-EVANS said that drugs and medical supplies were only stored in military hospitals in quantities sufficient approximately for the current six months' requirements. Instruction in their storage was given as part of the course of dispensing, which all soldiers of the Royal Army Medical Corps had to pass before attaining the rank of sergeant. The examination at the end of the course was conducted by a board of medical officers.

**Dispensers in the Territorial Army.**—In a series of replies, on June 13th, to Sir Wilfred Sugden, Mr. DUFF COOPER (Financial Secretary of the War Office) said quartermasters of the R.A.M.C. (T.A.) were nominated by the officer commanding the unit, after consultation with the County Association. None of the quartermasters at present in the R.A.M.C. (T.A.) possessed the qualification of pharmacist. If a qualified pharmacist were recommended for appointment as quartermaster his claim would be gladly considered by the War Office, but at present there were no vacancies. No dispensers in the Territorial Army held the qualification of pharmacist.

**Cost Accounts of Naval and Military Hospitals.**—Answering Dr. Vernon Davies, on June 15th, Mr. A. M. SAMUEL said cost accounts in a common form had been compiled for a period of three months at one naval, one military, and one Air Force hospital, and had been considered by the Joint Medical Services Committee of the three departments. The modifications required in the common form before it would be suitable for general adoption had not been decided.

**Lack of Hospital Service in North Uist.**—On June 12th Sir J. GILMOUR told Mr. MacKenzie Livingstone that he was aware that there was no hospital in North Uist. The provision of an adequate hospital service was complicated by transport difficulties, by the comparatively small population to be served, and by the position of the Highlands and Islands (Medical Service) Fund, which was mortgaged to present commitments. The matter was, however, receiving consideration.

**Examination of Emigrants to Canada.**—On June 18th Sir E. THOMAS asked if Mr. Amery knew that there were widespread complaints that the new system of medical inspection had antagonized the British medical profession and created an atmosphere unfavourable to emigration to Canada, and whether he would discuss this with the Dominion Government. Mr. AMERY said he had seen press statements of the kind, but he was not.

prepared at present to express any opinion on the effect of the new system of medical inspection on the movement from this country. From the latest information in the press he gathered that it was proposed materially to modify the new system. From January 1st to April 30th the Canadian Government doctors rejected 1,740 persons in the United Kingdom as unfit for emigration to Canada.

*Noise of Motor Vehicles and Nervous Complaints.*—On June 6th Sir KINGSLEY WOOD told Sir Robert Thomas that the Minister of Health had no particulars of the number of patients who underwent treatment for nervous complaints in London hospitals each year from 1920 to 1927, nor in the first quarter of 1928. Sir Robert Thomas asked whether those responsible for hospitals and nursing homes in London did not think the trouble was due to the noise caused by the absence of silencers on motor cars and motor cycles. The SPEAKER, intervening, said Sir Robert was putting his own views. In a reply, on June 7th, to Sir Robert Thomas, Captain MARCESSON, answering for the Home Office, said that during the last six months of 1927 there were 6,622 prosecutions of motorists in the Metropolitan police district for excessive noise, and from January 1st to April 30th, 1928, 4,150.

#### Notes in Brief.

A scheme for provision of separation wards in Lambeth Hospital is being considered by the guardians.

The calves at Hendon are killed on the same day on which the lymph is collected. The carcasses and internal organs are fully examined by a veterinary surgeon for any morbid condition, including tuberculosis.

The report on post-operative tetanus submitted to the Scottish Office is still under consideration, and, on June 13th, the Secretary for Scotland could make no statement on it.

The provisional number of notifications of small-pox in England and Wales in the thirteen weeks ended June 2nd, 1928, is 4,239.

Commander Kenworthy presented in the House of Commons, on June 6th, a petition signed by 26,031 persons, asking for the prohibition by law of experiments on living animals.

There were 240,392 persons in receipt of relief in Scotland on January 15th, 1928. The number of lunatic poor has not varied much from May 15th, 1927, when it was 18,322.

Under the Refractories Industries (Silicosis) scheme seven committees have been set up to decide compensation to workers incapacitated by silicosis.

Sir Kingsley Wood states that it is not possible to make a reliable estimate of the present shortage of houses in England and Wales.

The number of deaths classed as due to childbirth in the boroughs of Kensington and Southwark in 1927 were respectively 2.26 and 2.57 per 1,000 live births.

## Medical News.

HIS MAJESTY THE KING will open the New University College Buildings at Nottingham, erected by Sir Jesse Boot, Bt., on the afternoon of Tuesday, July 10th.

THE annual general meeting of the Royal Society of Medicine will be held at 1, Wimpole Street, on Tuesday, July 3rd, at 4 o'clock, when the officers and council for the session 1928-29 will be elected, and the report of council will be presented.

THE prizes and certificates of the London (Royal Free Hospital) School of Medicine for Women will be presented by Dr. Arthur G. Phear, C.B., on Thursday, June 28th, at 4 p.m.; the chair will be taken by Lady Barrett, C.B.E. After the distribution of prizes the memorial porch in the north-east of the quadrangle will be unveiled by the Right Hon. Sir Francis Acland, Bt.

THE Fellowship of Medicine and Post-Graduate Association announces that a clinical demonstration will be given on Tuesday, June 26th, at 2.30 p.m., by Mr. Roeyn-Jones, in the out-patient department of the Royal National Orthopaedic Hospital, and on Wednesday, June 27th, at 3 p.m., Mr. Bickerton will give a clinical ophthalmic demonstration at the Royal Eye Hospital. From June 25th to July 21st there will be a course of lecture demonstrations on the diagnosis and treatment of common diseases of the nervous system at the West End Hospital for Nervous Diseases. Special courses will take place during July and August as follows: medicine, surgery, and special departments, Prince of Wales's Hospital, July 9th to 21st; proctology, St. Mark's Hospital, July 9th to 14th; medicine, surgery, and special departments, Queen Mary's Hospital, August 27th to September 8th; diseases of the chest, Brompton Hospital, July 30th to August 4th; diseases of infants, Infants Hospital, August 13th to 25th; neurology, All Saints' Hospital, August 7th to September 1st. Full particulars and information on the general course may be obtained from the secretary, Fellowship of Medicine, 1, Wimpole Street, W.1.

THE treasurer of King Edward's Hospital Fund for London has received a gift of £10,000 from an anonymous donor.

THE Minister of Health has appointed Lord Blanesburgh to be chairman of the Advisory Committee on the Welfare of the Blind in succession to the late Mr. G. H. Roberts.

THE Minister of Health has appointed Mrs. Barton, J.P., as an additional member of the Departmental Committee which, as recorded on June 9th (p. 1005), he set up shortly before Whitsun to consider the working of the Midwives Acts and conditions of employment of midwives.

DR. FRANK GOWER GARDNER has been elected county director of the British Red Cross Society for Oxfordshire, vice Colonel Stanier Waller, resigned.

THE following have been elected Fellows of the Royal Sanitary Institute: Dr. Cyril Banks (Hullfax), Dr. Henry Joseph Milligan (Reading), and Dr. Andrew James Shinnle (London).

AT the Commemoration Day ceremony at Livingston College, Leyton, on June 15th, the chair was taken by Dr. G. Carmichael Low, senior physician, Hospital for Tropical Diseases and Seamen's Hospital, who gave a brief address on the development of tropical medicine. Dr. Low described the progress made in the treatment of such diseases as malaria, yellow fever, kala-azar, and plague, and emphasized the value of some training in tropical medicine for all who went abroad. Many of the students of the college, he said, were treating yaws, sleeping sickness, and leprosy under the direction of the Government medical services in Africa and in other lands. The Southern Rhodesian Government were now making money grants to those who had had the full training at Livingston College, to help them with their dressings and medicines. Mr. S. Peake, a missionary who has been working in South India for the past twenty-nine years, referred to the value of teaching missionaries to care for their own health and that of their colleagues when far from qualified medical aid. Dealing with work among others he said he had treated nearly 100,000 people at his dispensary. The principal of the college stated that 1,020 students had passed through it for training, and asked for the support of missionary societies by sending their candidates for training. The college requires the sum of £400 to enable it to close the financial year without a deficit.

MESSRS. H. K. LEWIS, the well-known medical publishers and booksellers of Gower Street, have issued a small pamphlet giving details of the service which they have built up as a result of eighty-four years' specialized experience. Their publications have included the works of such men as Jenner, Lister, and Osler, and to-day cover a very wide field, while the bookselling department maintains a stock comprising every important new English book on medicine or surgery, besides many other scientific and technical works, and its resources include arrangements for obtaining foreign publications. Lewis's circulating library offers facilities for the most persistent borrower, and is provided with a reading and writing room, where books may be inspected and works of reference consulted.

TWO further pamphlets, forming parts of the *Encyclopaedia of Industrial Health*, which is being issued serially by the International Labour Office, and will ultimately appear also in volume form, have been published. One of these (comprising Brochures Nos. 95 to 100) deals with electricity as a cause of industrial hazards; flax and linen industry; phosphuretted hydrogen; goggles; hemp manufacture; odours. The other (Brochures Nos. 101 to 108) relates to arsenobenzol; artificial flowers and artists; liftmen; the stone industry; sulphate of soda; sulphuretted hydrogen; nitrogen; aminophenols; anisidines; anthraquinone; anti-moniuretted hydrogen, and apotropane.

DR. EMIL ABDERHALDEN, professor of physiology at Halle University, has been nominated an honorary member of the Chinese Physiological Society at Peking; Dr. Paul Schubert, professor of neurology at Berlin University, has been nominated an honorary member of the Società Italiana Oto-neuro-Oftalmologica; and Dr. Karl Scheele, professor of surgery at Frankfurt, has been nominated corresponding member of the Società Italiana di Urologia.

THE following appointments have recently been made in foreign faculties of medicine: Professor Giuseppe Corania, director of the paediatric clinic at Rome, has been transferred to the chair of infectious diseases of children at Naples; Professor Luigi Spolverini has been appointed director of the paediatric clinic at Rome; Professor Rocco Jemma has been nominated director of the faculty of medicine at Naples; Professor Noyous of Louvain has succeeded Professor Zwaardemaker in the chair of physiology at Utrecht; Dr. Erich Freiher von Redwitz has been appointed professor of surgery at Bonn, and Professor R. L. Porter dean of the

faculty of medicine at San Francisco; Professor von Economo of Vienna, professor of neurology at Zürich; Professor von Haberer of Graz, professor of surgery at Düsseldorf; Professor von Gaza of Göttingen, professor of surgery at Rostock; Dr. Angiola Borriuo, professor of clinical pediatrics at Sassari, Sardinia; and Dr. Karl Lindner, professor of ophthalmology at Vienna in succession to Professor Dimmer.

The report of the Huntington Memorial Hospital for Cancer Research and the associated laboratories, controlled by the Cancer Commission of Harvard University, for 1926-27 contains an interesting account of the increase in facilities for the diagnosis and treatment of cancer in the State of Massachusetts. Reference is made to the opening of several new voluntary hospitals and clinics dealing with this disease, and to the establishment by the Department of Public Health of six cancer clinics and a State cancer hospital. The publicity secured by these developments has led more people to seek advice for incipient or unsuspected cancer. In the year 1926-27, in spite of the creation of so many new institutions, the number of cases dealt with at the Huntington Hospital showed a considerable increase. There is, in connexion with the laboratories, a free diagnosis service for pathological material supported by the Massachusetts Public Health Department and available for every registered medical practitioner in the State.

An Ordinance to make provision for the medical inspection of school children in Trinidad and Tobago has received the Governor's consent. Under this Ordinance the Governor is empowered to appoint members of the Medical Board of Trinidad, and such officers as he may consider necessary for the purposes of the Ordinance, to be school medical officers. A school medical officer has the right to enter and inspect, with or without notice, any school during school hours, and must report on his inspection to the Surgeon-General. He may arrange for the medical inspection of all pupils attending any school. The Governor in Council may make regulations prescribing the nature of the medical inspection of pupils attending school, and the forms and records to be used in relation to such medical inspection.

THE jubilee of the Queen Elisabeth Sanatorium, Budapest, which was the first tuberculosis sanatorium in Hungary, is being celebrated by the laying of a commemoration stone and the unveiling of a statue of the founder, the late Professor Baron Frederick von Korányi, who was also the founder of the Budapest society now responsible for the institution—an organization devoted to the provision of sanatorium facilities for persons of limited means.

THE area of Hungary was reduced by the war from 125,402 square miles to 35,870. Its present-day population is 7,980,143. Prior to the war Hungary was a constitutional and hereditary monarchy. In 1918 King Charles abdicated, and a republic was declared. After a brief experience of Soviet misrule the national government was restored, and Hungary is now a monarchy with a vacant throne under a regent. The local administrative areas are counties and boroughs, the former subdivided. The Minister of Labour and Social Welfare, who is responsible for health administration, is advised by the National Public Health Council, whose members are selected from distinguished workers in the medical profession. The State Health Institute attached to the Ministry supplies a laboratory service. There had been countings of the people since 1494, but the first modern census of Hungary was in 1869; since then the census has been taken at approximately decennial intervals. Registration began in 1784, when the clergy were required to keep the registers. In 1894 it was placed on a civil basis. Births must be declared within seven days and deaths within two, the former by the father or his substitute, the latter by the nearest relative, the doctor in attendance, or the head of the household. The birth rate in 1925 was 28.3 and the death rate 17.1. There are several statistical publications, printed in Magyar, German, and French. The usual infectious diseases are notifiable, together with plague, yellow fever, pellagra, ankylostomiasis, and rabies. Medical practitioners are primarily responsible for notification. Outbreaks of infectious disease must be reported by local authorities to the Ministry of Labour and Social Welfare within twenty-four hours of their occurrence. Vaccination and revaccination under 12 years of age are compulsory. Tuberculosis is the subject of a special campaign. The tuberculosis death rate in 1925 was 2.4 per 1,000. Nearly 90 per cent. of the people of Hungary are now ethnically Hungarian, and the Hungarian language predominates.

SIR ROBERT PHILIP, President of the British Medical Association, has been awarded the Trudeau Medal, which is given annually to the individual who has made the most meritorious contribution to the knowledge of the cause, prevention, and treatment of tuberculosis.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to *The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.*

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM 9561, 9562, 9563, and 9564* (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:  
EDITOR of the *British Medical Journal*, *Aitiology Westcent, London.*  
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*  
MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

## QUERIES AND ANSWERS.

### STATUS EPILEPTICUS.

"H. C. B." asks for suggestions as to the treatment of this condition in a child 9 years old, subject to fits from infancy. The attacks are extremely severe, the violent (convulsive) stage lasting about 10 hours, and forty-eight hours of complete unconsciousness follow. They are preceded by a series of a few hours between each. Of late the child has had an attack about every fortnight. Bromides, chloral, and paraldehyde per rectum, even in large doses, do not have any effect. Neither chloroform nor morphine has been employed, and information as to the advantages and dangers of these would be much appreciated, and also as to any electrical or mechanical treatment. Whatever its cause, there is obviously in status epilepticus a tumultuous and uncontrolled discharge of nervous impulses. It does not seem unreasonable to think of tapping and short-circuiting these by means of some appliance to the head and spine, or of influencing them by the passage through the body of an electric current.

### TREATMENT OF CHRONIC NASOPHARYNGEAL CATARRH.

DR. J. VAN MILLINGEN (Harlesden) writes: I would advise "C. C." (May 22nd) to try the following:—  
"I have tried to clean out a house by pouring a bucket of water through the front door and out at the back. Sprays have the same disadvantage, as they do not reach the various chambers and passages of the nasopharynx. He will find insufflation by far the most effective method; it has given me most satisfactory results during the last five years of my practice. I have practised it in about eighty cases, some of which have been exceedingly chronic. Among these were three of atrophic rhinitis, which so far improved as to be free from two most objectionable features of this disease—namely, ozæna and a constant desire to free the nose from the obstruction; two true hay fever cases, in which no attacks occurred during the period of treatment, and one patient who had had seventeen seasonal attacks, completely escaping during the period of treatment; and three patients with catarrhal deafness, one of whom recovered completely in a fortnight and the other two so improved, after life-long deafness, as to be very gratified with the result. It is immaterial what powder is used, but it is important that one should cease using any particular powder as soon as unpleasant symptoms supervene and then choose another powder having a totally different action. Treatment should be from one to three months; most of my cases showed improvement in two or three weeks. The powders recommended are iodol, orthoform, and 10 per cent. eufarine in casein alb. (soluble). Insufflation renders it possible to detect cases of deeper significance than nasal catarrh, for those which are not cleared up by this method should be sent to a specialist for further investigation and treatment."

### MIGRAINE.

"M. D." writes to say that "M.R.C.S.," whose query appeared on June 2nd, will find in the *British Medical Journal* of April 9th, 1927 (p. 700), a note on the treatment of migraine.

## INCOME TAX.

## Division of Partnership Assessment.

"A" and "B" are equal partners, the firm's accounts being made up to December 31st. "A" retired on March 31st, 1928. What is his liability, if any, to income tax in respect of the profits for the period from January 1st, 1927, to March 31st, 1928?

\* \* \* The assessments already made, on the statutory basis of past profits, cover "A's" liability up to March 31st, 1928, and when he has discharged his share of the liability so created he will have paid tax on the income earned by him up to March 31st, 1928, whether he has actually received it or not. "B" will be liable for the year 1928-29 on the basis of the amount of the firm's profits for the year 1927, except that, if he can show that the actual profits for the year to April, 1929, have fallen short of that amount from some specific cause—for example, the payment of an assistant employed by him—then he can claim a reduction of his liability accordingly.

## Motor Car Transaction.

"D. G. W." bought a M. C. car in 1922 for £314 and sold it in December, 1927; in January, 1928, he bought a second-hand M. O. car for £150—new cost, £220.

\* \* \* In our opinion he is entitled to deduct the net out-of-pocket expenditure—that is £150—£25=£125—as a professional expense applicable to the year which includes January, 1928. If his annual accounts are made up to December 31st, this implies that the financial year affected will be that ending April 5th, 1929.

## Deductible Expenses.

"E. J. M." asks for "a list of items that a medical man can deduct from his income on account of income tax."

\* \* \* The circumstances vary so much between different practices that such a list would be lengthy if it covered every possibility, and might be misleading, as suggesting the propriety of deductions only claimable in special circumstances. The statutory rule is that allowable expenses must be incurred wholly and exclusively in earning the income, but that does not prevent the allowance of a reasonable proportion of charges which cover private as well as professional use—for example, a proportion of rent and rates or telephone rent. It may perhaps be useful to mention one or two expenses which are sometimes overlooked, such as a proportion of the cost of board and laundry of a domestic servant employed partly on the professional rooms, the expense of having accounts prepared or audited, bank interest or charges for keeping the practice account, or stationery and postage.

## LETTERS, NOTES, ETC.

## ORAL ADMINISTRATION OF PANCREATIC PREPARATION.

DR. R. D. LAWRENCE (London, W.) writes: Since writing a condemnation of the oral administration of pancreatic preparations in diabetes in your issue of May 19th (p. 875), I have been informed that Messrs. Parke Davis's pancreatic capsules were never on sale to the public, and have not been manufactured for the last two years. At their request I am glad to rectify any misunderstanding that my letter may seem to have cast on this firm.

## TREATMENT OF HAEMORRHOIDS BY THE GALVANO-CAUTERY.

DR. W. S. WHITCOMBE (London, W.) writes: I should like it to be known as far as possible by those who may have adopted my method of treating haemorrhoids by the galvano-cautery (*Journal*, 1925, vol. ii, p. 992) that, very rarely, cases occur (two in three years with me) of rather alarming second attacks occurring on the fourth day after treatment. As my patients are of the size of a pin's head such patients must have a strong haemophilic tendency. There is no danger, in my experience, if they are treated with haemostatic serum and packing.

## MIXED SCHISTOSOME INFECTION.

DR. F. G. CAVSTON (Durban, South Africa) refers to Dr. H. Fairbairn's memorandum on vesical bilharzia (*Journal*, January 14th, p. 52), and writes: The presence of *Schistosoma haematobium* is to be expected in Natal inhabitants infested with *S. mansoni*, *S. spindalis*, or *S. (f.) bovis*, for the same individual *plusopsis* may serve as the carrier for more than one of these parasites. Unfortunately, the urine collected for examination is sometimes obtained from the chamber, and many ova are thus missed. Wherever possible, the last portion should be passed into a wide test tube, for it is the last ounce or two which contains the ova. It is not uncommon to find what are generally regarded as skin parasites or their ova—as, for example, *Tyroglyphus longior*—amidst the bilharzia ova. The urine of two brothers, infected through bathing in the Palmiet River, near Durban, contained ova resembling those of *S. haematobium* and *S. bovis*. While showing these latter ova, which I have found previously in only six cases, all from the same locality, to Dr. Norman Walker at the Natal Pathological Laboratory, we found a *fasciola* ovum in the urine

of one of the patients. This boy had just received his first dose of carbon tetrachloride, which is regarded by veterinary surgeons almost as a specific for *fasciola* infestation.

## PSEUDO-APPENDICULAR ENCEPHALITIS LETHARGICA.

DR. A. T. HEPPLIE MARSDEN (South Shields) refers to G. Cantiero's account of a case of the pseudo-appendicular form of encephalitis lethargica (*Eptome*, December 31st, 1927, para. 603), and reports another case of the same kind. He writes: A lad, aged 18, complained of sore throat and "feeling queer"; he told me that he had felt drowsy for the last week and answered questions very slowly. He had a dull, expressionless face; the wrinkles were smoothed and the face muscles could only be moved with difficulty, while diplopia, double ptosis, and strabismus were present. A coarse tremor occurred periodically. The right Babinski sign was extensor and the left slightly so; all other reflexes were normal. The Wassermann reaction was negative, and the temperature was 99° F. He had a superficial tonsillitis and a vague pain in the abdomen about the umbilicus. On the next day the pain in the abdomen became much more severe and settled in the right lower abdominal quadrant; he had an attack of nausea, but no vomiting. There was tenderness at McBurney's point and sharp pain followed sudden lifting of the hand after deep pressure; pain in the appendix area was caused by pressure over the left side of the abdomen directed towards the middle lobe. There was rigidity over the left iliac fossa, but no mass could be felt. Constipation followed; there was a burning pain on micturition and the urine felt hot. The appendicitis resolved satisfactorily, all pain and other symptoms disappearing in three days. The encephalitis also commenced to clear up; in five days the facial muscles had recovered, and the lethargy was almost gone, but there was slight pyrexia for three weeks. At the end of six weeks he appeared to have recovered, except that he remained rather dull and apathetic. This would appear to have been an acute enteral appendicitis occurring during the course of an encephalitis lethargica, but the differential diagnosis from the pseudo-appendicular form of encephalitis lethargica must often be very difficult. Symptoms and signs pointing to appendicitis would be signs of involvement of other structures in the inflammation—as, for example, the pelvic peritoneum, the right lateral wall of the rectum, the psoas muscle, and the formation of a mass in the right iliac fossa. Continuance of the pain and temperature, without increase in the signs and symptoms, would point to the pseudo-appendicular form of encephalitis lethargica.

## HEAT CRAMP AND HEAT HYPERPYREXIA.

DR. GEO. P. F. ALLEN (Kingston, Jamaica) writes: Dr. J. S. Haldane, in his letter on heat cramp (*April 7th*, p. 609), stresses the importance of "osmotic pressure," which appears to me to play a very important part in the etiology of the allied condition of heat hyperpyrexia. It is generally assumed that heat hyperpyrexia is due to the direct action of solar or atmospheric heat on the body, and many theories of the *modus operandi* of this assumed cause have been advanced, none of which will explain all the features of the condition. Hearn, has pointed out that suppression of sweat is a constant association, and usually occurs many hours before the onset of the hyperpyrexia. He believes that this suppression of sweat is due to paralysis of the sweat glands. Now sweat is manufactured by the sweat glands from lymph which has passed out from the blood vessels into the lymph spaces around the glands. Heat hyperpyrexia occurs in patients who previously have been sweating profusely, and if the suppression of sweat is due to failure of the glands, then oedema due to the accumulation of exudate in the lymph spaces ought to be a constant feature; but in actual practice this is found not to be the case. It is known that a hypodermic injection of atropine increases the liability to an attack of heat hyperpyrexia. The action of atropine on the salivary glands was studied experimentally by Heidenhain many years ago. He found that the depression of the secretion of saliva was not accompanied by any accumulation of lymph in the lymph spaces, and the glands were not oedematous. From this he concluded that the diminution in the secretion was not due wholly to paralysis of the secretory nerve endings, but also to some decrease in the permeability of the vessel walls. By analogy, then, it seems likely that the suppression of sweat in heat hyperpyrexia is due to relative impermeability of the blood-vessel walls; and this is a point that ought to be considered in treating those cases, whatever may be the nature of the substance that produces this alteration in the osmotic pressure.

## OMPHALOGY.

"G. H. G. D." writes from Manchester: I had a confinement yesterday. The other member of the family is a boy of 4. To-day he stood solemnly watching the nurse bathing the new arrival, when, suddenly pointing to the umbilical stump with its knotted ligature, he asked, "Is that where God tied the label on?"

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 48, 49, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 275.

## An Address

ON

THE PLACE OF BIOCHEMISTRY  
IN MEDICINE.DELIVERED AT THE OPENING OF THE COURTAULD INSTITUTE  
OF BIOCHEMISTRY AT THE MIDDLESEX HOSPITAL  
ON JUNE 14TH,

BY

SIR ARCHIBALD GARROD, K.C.M.G., D.M., F.R.S.

For more than a century past every medical man has had, in his consulting room or near it, a shelf with a few bottles of reagents, a spirit lamp, and some test tubes, with which to carry out certain simple chemical investigations which form part of clinical routine. That shelf is the prototype of this great institute, with which the munificence of Mr. Samuel Courtauld has enriched the Middlesex Hospital; and the contrast between prototype and achievement is no greater than that between the medical chemistry of a hundred years ago and the biochemistry of to-day.

Indeed, the year 1828 marked an epoch, for in it the German chemist Wöhler, afterwards the fellow worker with Liebig, obtained that most abundant product of animal chemistry, urea, as a result of a reaction in the laboratory, and so began the removal of the barrier which was believed to separate organic from inorganic compounds—the chemistry of living things from the chemistry of the rocks.

*Early Association of Chemistry with Medicine.*

But the association of chemistry with medicine dates back much further. Even the alchemists tried to prepare the elixir of life. In the early part of the sixteenth century lived that eccentric genius who called himself Paracelsus, who looked upon medicine from the standpoint of chemistry; and in the sixteenth century was born van Helmont, who has been called the father of chemical physiology, of both of whose contributions you may read in Michael Foster's *Lectures on the History of Physiology*. In the seventeenth century our countryman Thomas Willis discovered glycosuria. Many of the pioneers of chemistry were medical men, some of whom occupied chairs both of medicine and of chemistry; and so medicine has played an important part in the building up of this, as of other branches of pure science, and often provided the early chemist with a means of gaining his livelihood. In return chemistry has rendered immense services to the advancement of medicine.

Wherever a medical school was founded a professor of chemistry was appointed, and in Edinburgh, at the end of the eighteenth century, there was a remarkable group of chemist-physicians, which included Cullen, Joseph Black, the discoverer of latent heat, and Daniel Rutherford. In those days numbers of future physicians, and amongst them not a few graduates of Oxford and Cambridge, went to Edinburgh for their clinical training, and some of these, returning to London, brought with them the current teachings of the school. Amongst these was Alexander Marcet, a native of Geneva, and afterwards physician to Guy's Hospital, who made some valuable contributions to pure chemistry, as well as to chemical pathology. A slightly older contemporary was William Hyde Wollaston, a Cambridge man, the discoverer of the ductility of platinum, a property of far-reaching value to chemists and physicists. Wollaston, who abandoned medical practice after failure to be elected to the staff of St. George's Hospital, devoted himself to pure science, and gained distinction in physiology, pathology, mineralogy, optics, and botany. He was the first to make a scientific study of the composition of calculi. A junior contemporary of these, and like Marcet an Edinburgh graduate, was William Prout, who is entitled to a very high place among the founders of chemical physiology, for he was the discoverer of hydrochloric acid in the gastric juice—a vital finding in connexion with the physiology and pathology of digestion. He won fame as a chemist also; for his celebrated hypothesis that the atomic

weights of other elements are multiples of that of hydrogen and that from hydrogen all other elements are derived has ever since set chemists thinking, and has proved a powerful stimulus to research.

The generation which succeeded these men in London produced another group of chemist-physicians, whose work was carried out in the middle years of the last century. Among them Henry Benze Jones may claim a prominent place. He was a pupil of Thomas Graham, who first investigated the colloid state, and of Liebig, and a friend and the biographer of Faraday. His best remembered contribution to medical chemistry was the discovery in urine of the peculiar protein substance which bears his name. Among his contemporaries, and also a pupil of Thomas Graham, was my father—not to refer to him in this connexion would be the outcome of a false modesty. He, in 1848, by means of a test of extreme simplicity, but which calls for some skill to carry it out, demonstrated the presence of uric acid in the blood of gouty subjects, and estimated approximately its amounts. Thus was chemical examination of the blood of living persons first made available as a means of diagnosis; and the developments of such methods, in the hands of Bang, Folin, and others, are familiar to students at the present day. These modern methods yield, with small quantities of blood, drawn from a vein or even from the lobe of the ear, results of great accuracy and diagnostic value. Somewhat younger contemporaries were Thudichum, whose work is now better appreciated than formerly, and Frederick William Pavy, who devoted much time throughout a long working life to the study of diabetes, but did not live to see the discovery of insulin. He it was, also, who first described cyclic albuminuria. It is told that one of his colleagues at Guy's Hospital, himself a great physician, expressed surprise that Pavy should devote all his best energies to the study of an incurable malady; but granting that even now we cannot cure diabetes, the advance made towards that goal shows that the time and energy of those who have worked at the subject have not been wasted.

Meanwhile, in a wider sense, and in a far wider field, the study of animal chemistry was advancing steadily. Much of the advance was due to the teaching, influence, and opportunities of research provided by Justus von Liebig in his laboratories at Giessen, and later in Berlin; and there come to mind the names of other great biochemists of the nineteenth century, among them those of Pasteur, Wurtz, Hoppe-Seyler, Karl Schmidt, Emil Fischer, Huppert, and Arthur Gamgee, to mention only a few.

Nowadays very different conditions prevail. A considerable number of those who obtain medical degrees or qualifications turn aside from the path of practice and devote themselves to laboratory work in the medical sciences, as pathologists, physiologists, biochemists, or pharmacologists. For these men it has been necessary to provide adequate accommodation. The Institute of Physiology no longer houses both biophysics and biochemistry; pathology has split into several branches—namely, bacteriology, morbid anatomy, and pathological chemistry. In biochemistry far more work is being done, and those who pursue it are almost all able to devote their whole time to it. The names of living biochemists who have done or have surpassed such work as that of our forefathers referred to, form a very long list, in which our own countrymen occupy a place of which we may be proud. Centres of biochemical teaching and research, such as that over which Sir Frederick Hopkins presides at Cambridge, are now being formed in various universities in this country, and we are met together for the inauguration of the latest of these to-day.

*Bacteriology and Chemical Pathology.*

It must not be forgotten that the aims and methods of the several branches which are included under the collective name of pathology differ considerably; and this is specially true of bacteriology and chemical pathology, although in the field of immunity they overlap and must collaborate. The bacteriologist studies the actual agents of disease, the stone which, as it falls into the pool, ruffles its surface, whereas the biochemist studies the ripples which spread outwards in increasing circles, from the

point of impact of the stone—in other words, the disturbances of the metabolic processes which result from the bacterial invasion.

Of recent years, under the spell of the advances of bacteriology and protozoology, we have tended to lay all the stress upon the invading malady and to pay too little attention to the reaction of the organism invaded, but there are signs that the pendulum is returning from the limit of its swing, and in its modern dress the revived doctrine of diathesis will rest largely upon a chemical basis.

The newer biochemistry does not restrict itself any longer to the older problems of chemical constitution and the products and methods of metabolism. The physico-chemical aspects of the subject are receiving more and more attention. We may hope that, important as those aspects are, they will not so engross attention that the older problems will be neglected.

Not only does the modern pathological chemistry embrace a far larger field, but the simple methods of our predecessors no longer suffice for its requirements. Examinations of greater and greater delicacy are called for; apparatus is needed which requires ample laboratory space, and which is itself often costly. No wonder that the cost of hospital equipment and upkeep has increased greatly. Fortunately donors are beginning to realize that by providing a great hospital with such an institute as this they are rendering as much, or more, aid to the sick and suffering around us as by the addition of so many more beds. The value of a hospital depends not only upon the number of patients treated, but also upon the quality of the relief given, and, as I shall hope to convince you, the value of such a hospital as this, and the good which it does, is not limited to the area in which it is situated, nor even to its wider clientele; but, so far as it is a place in which knowledge is increased, its influence extends to wherever medicine is taught, and those who are trained here diffuse its teachings all over the world.

#### *The Importance of Biochemistry in the Diagnosis, Prognosis, and Treatment of Disease.*

Let me try, then, to set before you wherein the importance of biochemistry to medicine consists, and why such departments as that which has been opened here to-day are desirable, or even essential, parts of the equipment of such a hospital as this. Let me speak first of the more strictly practical aspects of my subject, of the aid which biochemistry affords in the diagnosis, prognosis, and treatment of disease.

There are a few maladies the diagnosis of which rests upon chemical evidence, or in which the chemical processes are usually the key. It is often the case with diabetes, which is not infrequently first detected on examination of the patient for life insurance, and the earlier the recognition of the malady the better is the prospect of treatment. Indeed, all through the course of diabetes chemical tests are of value, as indicators of relapse or of response to treatment, as well as of the imminence of danger from acetonæmia. The estimation of glucose in a few drops of blood is of special value, especially in distinguishing between true diabetes and varieties of glycosuria which are apparently harmless, which call for no restrictions of diet, and in which such restrictions may be undesirable. From such examinations also the effects of dietetic and insulin treatment can be determined. Again, the reducing power of the urine may be due to sugars which are not glucose, and have quite different significance, and these can be recognized by various chemical tests.

The modern methods employed in these examinations of glycosuric patients demand technical skill in the examiner, and a variety of manipulations which are best carried out in a laboratory.

Another disease which has always been classed as a disorder of metabolism is gout. It looms less largely on the popular, as well as on the medical, horizon than was the case twenty or thirty years ago. Two factors combine to bring this about. First, a large number of conditions formerly classed as gouty are now referred to other categories—oral sepsis or what not; and secondly, owing pre-

sumably to change of habits and modes of life, true gout, the podagra of the ancients, is much less common in London than it used to be. How rarely do we now see the chalk-stones upon the hands, with which our forebears were falsely reported to have been able to score upon the cloth of the card-table. Now that we can measure with accuracy the amount of uric acid in small quantities of blood we can exclude the cases which do not fall into the strict category, and include others the goutiness of which is apt to cause surprise.

There are various rare conditions for the recognition of which testing of the excreta is essential; and by such chemical tests it is often possible to detect a drug which has been administered. Some poisons also are found by examination of certain tissues, such as arsenic in hair.

Chemical tests may afford most important evidence as to the functional efficiency or otherwise of certain organs, and these tests have been multiplied and greatly elaborated in recent years.

In most cases a diagnosis consists of two parts—namely, the nature and the seat of the disease—and it is with the seat that we are at this moment concerned. The detection of albumin in the urine is one of the oldest means of detecting damage to the kidneys, but, as with glycosuria, not all albuminuria is of evil omen. In more recent years the tests of renal efficiency have been greatly multiplied, and have become more delicate: by the administration of urea by the mouth and the study of its excretion we may measure the efficiency of the renal apparatus; by the administration of certain other substances we may obtain information as to which part of the renal apparatus is chiefly at fault. Moreover, by estimation of urea in the blood or cerebro-spinal fluid we can learn about the efficiency of the kidneys from the other side, so to speak, and gain information as to accumulation in the blood and tissues of substances which it is the function of the kidneys to get rid of. So we can estimate the risk of uræmia in a patient whose kidneys are diseased, although urea is not the cause of uræmia, and we do not yet know what is its cause.

Tests on somewhat similar lines, such as administration of levulose by the mouth, and estimation of the tolerance of that sugar, which is more readily excreted in the urine when the liver is diseased, or by the determination of the sugar curve in the blood after its administration, afford valuable evidence as to the functional efficiency of the liver.

One of the most important, and at the same time most elusive, of our organs is the pancreas. Deeply seated as it is, it is almost out of reach of direct clinical examination; only in comparatively recent times was the part played by this gland in connexion with carbohydrate metabolism discovered by von Mehling and Minkowski. Yet, by putting two and two together, by the cumulative evidence of a series of tests, it is often possible to reach a correct diagnosis in cases of pancreatic disease. These tests are for the most part chemical, and the determination of the nature and amounts of the fatty substances discharged from the intestine is the most important of them.

To Prout's discovery of hydrochloric acid in the gastric juice I have already referred, and in recent years methods of increasing delicacy and efficiency have been devised, and are in common use, for the chemical examination of the gastric or duodenal juice obtained after a test meal or by passage of a duodenal sound.

The metabolic processes at work in the living organism are of almost infinite variety; special enzymes are entrusted with each small metabolic task, and if one fails, or is lacking, more or less conspicuous derangements result. We can no longer regard the body as a simple furnace in which the food supplied is burned without discrimination. Nevertheless it is sometimes useful to determine the sum total of the chemical activities of which the body is the seat, and this may be carried out without much difficulty. For example, the metabolic fires burn up, or burn low, according as the thyroid gland is functionally overactive or supplies too little of its hormone; and so by determining the amount of oxygen utilized we may estimate the well-being or otherwise of the thyroid gland.

It is true that these tests can seldom be carried out by

a doctor in busy practice; but it is one of the chief uses of such a department as this to help the practitioner as well as the hospital staff, by reporting upon material submitted to it. In this way the benefits of the biochemical department reach a much wider circle than the staff and patients of the hospital to which it is attached. It may be objected that the more elaborate investigations must needs take time, whereas medicine is always in a hurry, and cannot wait. Grave disease often strikes quickly, and it may be necessary to act before a report can be received. This is true in some cases, but in the majority there is no such urgent haste; and modern diagnostic methods would prove a curse rather than a blessing if the practitioner, trusting to them, neglected to acquire a thorough knowledge of the older methods of diagnosis, which rely upon the use of hands, eyes, ears, and nose. These instruments he has with him always, and, when properly used, they serve him well.

I might go on to speak of the use of chemical tests in prognosis, which is perhaps the most difficult province of medicine. This is well seen in connexion with diabetes. In the domain of treatment, also, biochemistry plays an important part. A better knowledge of the constituents of diet, their utilization, and needful proportions, together with the discovery of vitamins, is revolutionizing the science of dietetics, or rather is creating such a science.

#### *Functions of Biochemical Laboratories.*

I trust that I have said enough to make it clear that the practical applications of biochemistry are of great use for the solution of the problems which confront us at the bedside; that they help in the diagnosis, prognosis, and treatment of disease. That in itself is enough to justify the establishment of biochemical laboratories in connexion with all hospitals. But if that were all we should feel much satisfaction, but not the enthusiasm which is experienced to-day by all who have the welfare of this hospital and its medical school at heart, on the occasion of the opening of this splendid institute.

There are two much greater functions which the institute will perform. In its generations of students will learn from competent teachers biochemical methods, and how to carry out the various tests which are so helpful in clinical work. It is true that many of them may not, in after-life, have the opportunity of performing these tests for themselves; but it is hardly necessary to insist on the point that he who acts on the result of a test should know how it is carried out. If he has himself learned how to do it he is better able to judge of its value and significance.

The students of the London schools distribute themselves over the world, and carry the teaching which they have received into remote parts of the earth. Obviously teaching is one of the chief functions of this institute.

To speak now of the third, and to my mind its most important, function. It is now recognized that, in addition to its teaching, every university and place of advanced study has as one of its duties the furtherance of original research, and that the advanced teacher will do his work better if he has himself advanced knowledge of the subject which he teaches.

Medicine may be looked upon from several distinct standpoints, but, in importance, the chemical standpoint is second to none, as is becoming more clearly recognized from year to year. Biochemistry is not merely a useful preliminary subject of study for the medical man, but is part of the very essence of his science, and, through his science, of his art.

We know that members of different genera and species of animals and plants differ from each other in chemical structure and chemical life, and evidence is accumulating that no two individuals of a species are any more identical in chemistry than in form. It would seem that there is a chemical basis for those departures from type which are styled mutations, and I for one believe that the liabilities of certain individuals to, or their immunity from, certain maladies—what may be called their diatheses—have chemical origins. Undoubtedly the mechanisms by which the body protects itself against bacterial invasions or poisons introduced aro, for the most part, chemical; and it is not necessary to point out the importance of the

parts played in the animal economy by such chemical substances as hormones and vitamins. If all this be true it is obvious that a chemical outlook is needful for the comprehension of morbid processes, and that there are unlimited openings for research in biochemistry.

Here young investigators will be guided and instructed in the methods of research by the professor and other experienced teachers, who will encourage and help them to pursue promising lines, and will extract them from the blind alleys down which they are so apt, in their inexperience, to wander.

Let us wish, then, to all who work within these walls, whether as teachers, learners, or investigators, good success. Let us wish, too, that the numbers of those who shall engage in biochemical research may be as large as the accommodation provided admits, for so will knowledge and wisdom be increased; and in the book of Wisdom it is written that "the multitude of the wise is the welfare of the world."

## ACUTE NECROSIS OF THE PANCREAS.

REPORT OF A SERIES OF CASES.

BY

J. W. GEARY GRANT, F.R.C.S.,

HONORARY SURGEON, ROYAL INFIRMARY, CARDIFF.

ACUTE pancreatitis, although one of the rarer causes of the acute abdomen, in some of its less acute and dramatic manifestations is possibly more common than is generally realized. In reading records of reported cases it is obvious that it is frequently diagnosed prior to operation as intestinal obstruction, perforation of a viscus, etc., by competent surgeons.

It has happened that in the past two years six cases of this condition have come under my personal observation—two in private and four under my care in the Cardiff Royal Infirmary. Prior to this period I had only come across or recognized one undoubted case, and in the above period, after a careful search, I have only been able to find records of five other cases in charge of the other surgeons of the hospital. By their courtesy I am permitted to include these in the following series. As several of these cases present some one or other feature of interest, and as the diagnosis is always difficult and early diagnosis is of vital importance, I have thought them of sufficient interest to record.

In Zachary Cope's *Early Diagnosis of the Acute Abdomen* it is stated that "pancreatitis is a rare condition seldom diagnosed correctly before operation, occurs most commonly in men, and for the most part is only met with in those over middle age." In the following series of twelve cases no fewer than ten occurred in women, and in seven of these their ages ranged from 20 to 33.

A brief analysis of these cases shows: Males, 2 cases; ages 55 and 69. Females, 10 cases; ages 20, 22, 25, 26, 29, 32, 33, 54, 72, and 63. It is seen that whilst the age of the males is in agreement with that usually stated, that of the females shows a striking proportion of very young women, and in 3 cases where the sexual history is given parturition had taken place one month, six weeks, and three months respectively prior to the onset of the attack, and in the last case symptoms of gall-bladder trouble dated immediately from childbirth.

In 10 cases stones were found in the gall-bladder, and in 2 of these in the common duct, and of the latter one was found impacted in the ampulla of Vater, the common duct being greatly distended. In this case the patient died as the abdomen was opened.

At operation fat necrosis was found in 10 cases, hæmorrhagic fluid in the abdomen in 2 cases, "beef broth" fluid in 2, and straw-coloured serous fluid in 2 cases. Brocq states: "des deux phénomènes qui la caractérisent, l'hémorragie et la nécrose graisseuse, seul le premier est constant." In my series fat necrosis was the almost constant sign, whilst hæmorrhagic fluid free in the abdomen was found on only two occasions, and beef broth fluid on two other occasions.

In 2 cases suppurative cholangitis was found. In one of these (No. 4) small stones were present in the common

duct, but no signs of involvement of the pancreas. At necropsy, two days later, however, fat necrosis around the pancreas was found, and muco-pus in the duct of Wirsung. In the other case (No. 5) the patient, aged 72, had undergone cholecystostomy for gall-stones several years previously, and had been free from symptoms until the night before admission, when she was seized with pain that she described as worse than anything she had experienced with gall-stone colic. At operation the only sign of pancreatic disease was one patch of fat necrosis in the gastro-colic omentum, and on palpation the pancreas appeared normal. The main ducts were distended, readily admitting the index finger, and contained muco-pus, but no stones were found, either in the ducts or gall-bladder. At necropsy, some days later, the pancreas was found large, red, congested with numerous necrotic areas, and fat necrosis in surrounding tissues.

In Case 1 haemorrhagic fluid was the one sign which might have pointed to pancreatitis, but was attributed to bleeding from the omentum, which walled off a perforation of the gall-bladder. A week later, when the wound was opened up, the pancreas was found lying as a black slough in an abscess cavity.

In Case 11, after an indefinite illness following child-birth three months previously, where an operation on the gall-bladder was declined, a few days after leaving hospital the typical symptoms of a fulminating pancreatitis developed, with agonizing abdominal pain, constipation, tenderness, rigidity, and cyanosis. At operation a slough of the pancreas 3 inches long was picked out of a large abscess in the lesser sac.

The mortality in this series of cases was excessively high. As regards the operative procedures adopted:

- 2 patients recovered after simple drainage of the gall-bladder.
- 2 recovered where the gall-bladder was stated to have been normal and the pancreas was incised and a drain placed in its neighbourhood.
- 1 died after the same procedure.
- 2 died after drainage of the common duct for cholangitis.
- 1 died on the table as the abdomen was opened.
- 3 died after cholecystectomy for perforation or gangrene of the gall-bladder.
- 1 unoperated on.

The views of Deaver and Maugeret, that pancreatitis is due to infection from the biliary tract via the lymphatics, may theoretically be held to indicate the removal of the focus of infection in the gall-bladder, and may have influenced one in removing it. In the light of my present experience, even with a gangrenous gall-bladder, I should never attempt its removal if signs of pancreatitis were present, but content myself with drainage. The question of drainage of the common duct where with a shrunken gall-bladder this is not available is more difficult to decide. Holding the views of Opie, Moynihan, Brocq, and others, that the cause in most of these cases is the entry into the pancreatic duct of infectious bile or of bile during active digestion, if the common duct were distended and the technical difficulties did not entail too long a prolongation of the operation it would seem desirable to lower the pressure in the biliary system by drainage.

I feel, however, that in all cases where there is reason from the presence of haemorrhagic fluid or any areas of fat necrosis to suspect pancreatitis the condition of the pancreas should be inspected by direct vision after dividing the gastro-colic omentum. It is usually impossible to determine its condition by palpation only. If signs of oedema or haemorrhage are found it should be incised and drained.

#### CASE I.—*Acute Haemorrhagic Pancreatitis.*

A minister of religion, aged about 50, a year previous to his present illness, had an attack of gall-stone colic, for which he was treated at a spa with mineral waters.

On March 2nd, 1926, he was seized with violent abdominal pain, and was treated by injections of morphine without much relief. I saw him in consultation on March 3rd, at night, in the country. He was obviously in very intense pain, in the epigastrium, and was jaundiced moderately deeply. A diagnosis of acute obstructive cholecystitis was made. He was brought into Cardiff and operated on at 10 a.m. the next day.

*Operation.*—Right paramedian incision. The abdomen contained a quantity of blood-stained fluid which was thought to come either from a perforation in the gall-bladder or from a vessel in the omentum which was walling it off. There was no fat necrosis. The perforated gall-bladder was removed and found to contain stones. The vessels and ducts were ligated and a drainage

tube passed down to the stump. The pancreas was not explored, all the symptoms being attributed to the gangrenous and perforated gall-bladder.

For three or four days the patient's progress was satisfactory, then he was suddenly seized with abdominal pain and passed into a state of collapse. About two pints of glucose saline were given intravenously, and this was repeated the next day and the stomach was washed out. He rallied. The abdominal wound was opened up and pus escaped. The urine was found to be loaded with sugar, which persisted. He gradually sank and died in four days.

At a limited *post-mortem* examination the whole pancreas was seen to form a black slough lying free in an abscess cavity. There was extensive fat necrosis in the omenta and mesenteries.

#### CASE 11.—*Acute Pancreatic Necrosis.*

A married woman, aged 26, mother of one child, was admitted to the medical side of the Royal Infirmary on March 24th, 1925, for severe and persistent vomiting of three weeks' duration, which began about a month after the birth of her child. Vomiting came on ten to fifteen minutes after food, was copious, and was preceded by pain in the epigastrium passing back to between the scapulae.

On April 19th I saw her in consultation with the physician in charge with a view to operation for cholecystitis. She did not appear to be very ill, and there were then no physical signs, tenderness over the gall-bladder region, or rigidity, and it was almost impossible to get anything out of her regarding her symptoms. It was arranged to operate on her for cholecystitis, but she went home at her own request, refusing operation.

A week later I was called in by her doctor to see her. She presented the picture of an acute abdominal disaster. The abdomen was rigid all over and acutely tender. The pulse was about 160. There was a cyanotic tinge on the face. Her condition was desperate, but she was removed to a nursing home and operated on at once.

*Operation.*—Right paramedian incision. An abscess was found pointing through the gastro-colic omentum, and when opened a quantity of thick pus with faecal odour came away, together with a black slough of the pancreas four inches by one inch in size, lying freely in the abscess cavity. The retracted gall-bladder was so shrunken that it appeared impossible to drain it, and it was removed. It contained numerous small stones. A large tube brought out through the main wound was passed into the abscess cavity. It discharged quantities of pancreatic juice, which digested all the tissues with which it came in contact and set up a severe dermatitis, although every effort was made to prevent this.

She lingered on for a week.

#### CASE 111.

A woman, aged 32, had been in good health until two years ago, when she began to have attacks of pain and vomiting, lasting two to three days, with varying intervals of sometimes months.

On February 28th, 1927, she had a much more severe attack of pain in the epigastrium, radiating to the right costal margin, to the right inguinal region, and to the back. The pain was accompanied by vomiting. She was sent to hospital by her doctor as an emergency, but was not admitted. She was then sent to me as a case of gall-stones and was admitted on March 10th, 1927. She was very obese, and on admission did not appear to be very ill. The abdomen moved on respiration; there was no rigidity, but some tenderness in the gall-bladder region. Temperature 101° F., pulse 120, respiration 22. Urine, sp. gr. 1020, nothing abnormal. A diagnosis of gall-stones was made.

*Operation, March 12th.*—My house-surgeon remarked that he did not think much would be found. On opening the abdomen extensive fat necrosis was found in omentum and mesenteries. There was no free fluid in the abdomen. The gall-bladder was buried in adhesions to the transverse colon; when these were separated an area 1½ inches in diameter was found on the left side of its wall (gall-bladder) to be completely gangrenous. It was aspirated and then opened, and a quantity of a dirty brown bile was evacuated and two colonies of calculi, one being small round yellow stones, the other larger and faceted. The mucous lining was entirely gangrenous, and it was decided that it had to be removed. This was difficult owing to the depth of the wound and to the liver not rotating. The common hepatic duct was opened and a tube sutured in. Corrugated rubber drains were passed down to Morrison's pouch and to the neighbourhood of the pancreas below the transverse colon. A probe was passed through the ampulla of Vater into the duodenum, meeting no obstruction. One pint of glucose saline was given intravenously. Pulse 140, temperature 100° F.

From the date of operation to March 16th her pulse ranged from 124 to 134. Her temperature kept about 99° up to 100° F. until the 19th, when it reached its highest, 101°, with pulse 140. She felt very ill, with constant nausea, but no vomiting.

#### CASE IV.

A married woman, aged 29, was admitted as an emergency case with pain in the right hypochondrium passing to the right scapula, and vomiting of four days' duration. She had had five similar attacks during the previous nine months, accompanied by jaundice, and at times frequency of micturition. Her expression was anxious. The abdomen moved freely, but there was tenderness and slight rigidity in the right upper quadrant. The gall-bladder was palpable, the tongue moist and clean. There was no jaundice, but bile was present in the urine.

*Operation.*—Under chloroform and ether a right paramedian incision was made. The liver was propped. The gall-bladder was the size of a small pear, very tense, with distended pouch of Hartmann adherent to the common duct; it was removed from the fundus towards the ducts. The common duct was opened and found to contain thin, bile and flakes of muco-pus; two stones

one-sixteenth of an inch in diameter were removed with a scoop. French black gum bougies were passed with difficulty through the splinter of Oddi, and the duct was washed out with saline. No fat necrosis seen or blood-stained fluid in the abdomen. The common duct was drained.

The patient died on December 2nd, 1927.

**Necropsy.**—Acute inflammation in region of liver and numerous adhesions. Common bile duct much inflamed and necrotic in parts. Pancreatic duct also inflamed and containing mucopurulent exudation. Pancreas enlarged and firm and fat in neighbourhood showing necrosis. Spleen soft.

#### CASE V.—Acute Pancreatic Necrosis.

A married woman, aged 72, on whom I had performed cholecystotomy several years previously. She had had several attacks of biliary colic, but since the operation no trouble whatever until the night before admission. Gall-stones had been removed.

On September 30th, 1927, in the middle of the night, she was seized with a sudden attack of agonizing abdominal pain, which she described as being far worse than anything she had had in her previous attacks of gall-stone colic. She was admitted as an emergency with generalized abdominal pain.

**Operation.**—The gall-bladder was distended and adherent to the abdominal wall; adhesions were separated with difficulty. Dense adhesions of liver to diaphragm were not interfered with. The cystic duct and common bile and hepatic ducts were greatly distended; the latter was the size of the index finger, thin-walled, and of a green colour. It was aspirated and then opened: it contained mucopus but no stones. A probe passed down would not enter the duodenum. A tube was sutured in the duct. The gall-bladder was opened: it contained mucopus but no stones; a tube was sutured in. The pancreas was not felt to be enlarged. There was an area, 1 or 1½ inches in diameter, in the lesser omentum of fat necrosis.

For some days she appeared to be doing well, and bile drained from the tubes. The pulse ranged from 80 to 100, but not higher; the temperature remained normal. She died on October 10th, 1927.

**Necropsy.**—Stomach dilated, containing large amount of almost faecal fluid. Gall-bladder contained a small amount of pus, and ducts all showed intense inflammation. Liver friable. Pancreas large, red, congested, with numerous necrotic areas. Fat necrosis in surrounding tissues. Bile taken from gall-bladder at operation gave no growth on culture after three days.

**Post-mortem diagnosis:** acute cholecystitis and cholangitis, acute pancreatic necrosis.

#### CASE VI.

A married woman, aged 20, mother of one child, 1 month old, on August 29th, 1925, went for a walk for the first time after confinement. She was seized with sudden violent pain in the right hypochondrium and epigastrium, and vomited. The pain radiated to the right iliac fossa, back, and shoulder. The symptoms continued throughout the following day, and on August 31st she vomited four times.

She was admitted to the Infirmary on September 1st, at 9 p.m. Examination showed rigidity of both upper recti; Murphy's sign was present; the abdomen moved freely on respiration, but was tender all over. The face was anxious and pale. Pulse 103, temperature 98.4° F. The urine was loaded with sugar.

**Operation.**—On September 2nd the patient looked very ill; she had vomited twice in the night. Glucose was administered by the rectum. Temperature 99°, pulse 116.

A right paramedian incision was made. A quantity of blood-stained serum was present and on the omentum several patches of fat necrosis about an inch in diameter. A very tense gall-bladder 4 in. long by 1½ in. at the fundus, mottled yellowish-white, was found and incised. Brown bile under pressure escaped with small light yellow non-faceted calculi. It was washed out with saline, and showed a typical strawberry appearance, being a brilliant scarlet with yellow dots of lipid. A tube was sutured in it and a corrugated drain to Morrison's pouch. The abdomen was quickly closed with through-and-through silkworm gut. One hour after the blood sugar was 0.188 per cent., pulse 140, temperature 101° F.

On September 5th the urine contained 1 per cent. glucose, and acetone was present.

On September 27th the patient was convalescent.

#### CASE VII.

A very stout married woman, aged 63, had suffered from constant epigastric pain and vomiting for six months. In the early morning of February 21st, 1927, acute epigastric pain and vomiting set in. She was admitted as an emergency case and operated on at 1 a.m. on February 22nd. Pulse 138; slight cyanosis. The abdomen was distended, slightly rigid, and tender. There was no sugar in the urine. Loevy's test positive. Patient very ill.

**Operation.**—Gas-oxygen anaesthesia. Abdomen contained fluid like weak tea. Great omentum dirty grey in colour, with areas of fat necrosis, some the size of a threepenny piece. Owing to patient's condition the abdomen was closed with through-and-through silkworm gut sutures after placing drains down to the foramen of Winslow and root of the transverse mesocolon. She died at 3 a.m.

**Necropsy.**—Extreme obesity. Scattered foci of fat necrosis, especially in region of pancreas. No peritonitis. Pancreas enlarged, indurated, and on being cut into widely necrosed with black areas and practically no normal tissue left. Liver pale and fatty. Gall-bladder enlarged, containing numerous large faceted calculi. No stones felt in ducts.

#### CASE VIII.

A married woman, aged 25, was admitted as an emergency case for a sudden attack of abdominal pain of twenty-four hours' duration. Parturition six weeks previously. She was very stout. The abdomen was tender and slightly rigid.

**Operation.**—General injection of intestines, free serous fluid in abdomen. Greatly thickened omentum with areas of fat necrosis. Lesser sac opened through gastro-colic omentum. Pancreas bulged forward like a cyst. Punctured; two or three drachms of fluid like watery bile escaped. No growth on culture. Drained. Gall-bladder normal. The patient recovered.

#### CASE IX.

A married woman, aged 33, was admitted with a history of attacks of abdominal pain and vomiting, with slight icterus in some, of two years' duration. Flatulent dyspepsia. Four days before admission, on December 29th, 1926, she had a more severe attack.

On admission she was in great pain and looked very ill; her skin was yellow. Temperature 97.6° F., pulse 74. There was no distension or retraction of the abdomen. Movement impaired; tenderness over the right upper rectum.

**Operation** (January 3rd, 1927).—Omentum and mesenterics studded with areas of fat necrosis standing out prominently owing to bile-staining. The pancreas was palpated and found to be somewhat swollen, especially the head. The gall-bladder was not enlarged, but contained small stones estimated at 4,000. Cholecystotomy was performed.

The patient recovered.

#### CASE X.

A man, aged 69, was admitted as an emergency, with pain of nine days' duration referred to the whole abdomen. Constipation had been present for four days. The abdomen was distended.

**Operation.**—Large quantity of straw-coloured fluid in the abdomen. The patient died on the table.

**Post-mortem Examination.**—Extremely fat, slight icterus. Fatty heart; atheroma of coronaries. Acute inflammation of gall-bladder, which contained several large faceted stones. Common bile duct distended, contained a small stone in the ampulla of Vater. Acute haemorrhagic pancreatitis with fat necrosis in retro-peritoneal fat.

#### CASE XI.

A woman, aged 22, was admitted on February 11th, 1928, as an emergency case.

During the past two years she had had three attacks of abdominal pain and vomiting, lasting about two days. She had been getting thinner for the last six months and suffered from backache and severe frontal headache. She was a domestic servant, and had been out of work for two years on account of illness.

On admission she had had pain in the abdomen and back for twenty-four hours and had vomited. Later she had generalized abdominal pain, which doubled her up. That morning she had cramp in both hands, and had vomited four times. She was pale, thin, and anaemic, and looked ill. The abdomen did not move on respiration. The whole abdomen was rigid and tender all over—tympanitic; spasm of muscles caused flexion of wrist and extension of fingers (query tetany). Temperature 98.8° F., pulse 110.

**Operation** (February 14th).—Marked fat necrosis in the omentum, and in appendices epiploicae. Whole abdomen filled with odourless brownish fluid; pancreas exposed, appeared as a congested, purplish, tense swelling; incised, and swelling collapsed. Abdomen mopped out, cigarette drain inserted to pancreas. Gall-bladder appeared normal.

On February 17th there was no discharge from the wound, and the drain was removed.

On February 27th she was convalescing, but the temperature was swinging from normal to 101° F., pulse 100.

#### CASE XII.

A married woman, aged 54, had a sudden attack of epigastric pain on May 7th, 1928, followed by vomiting, after which the pain passed off. Both pain and vomiting recurred the following day. She was admitted as an emergency case on May 9th, but was too ill to be operated on. She died on May 10th.

**Necropsy.**—Liver, numerous pale areas on surface, fatty; gall-bladder, numerous stones. No stones in common bile duct or evidence of inflammation. Fat necrosis in omentum, round the pancreas and perirenal fat. Pancreas enlarged, with numerous haemorrhages; one longitudinal, one at tail.

In reporting these cases I have endeavoured to show that in spite of their extreme gravity, the early symptoms are not always such as would lead one to suspect the condition, and that, even at operation, in certain cases it is possible not to recognize it. If one only thinks of the classical symptoms of a fulminating pancreatitis operation may be delayed unduly.

I desire to thank my colleagues on the staff of the Cardiff Royal Infirmary for their courtesy in permitting me to include a report of the cases under their care.

## THE USE OF ADRENALINE IN MEDICAL AND SURGICAL PRACTICE.

BY

W. M. BEAUMONT,  
BATH.

THE service of adrenaline in medical and surgical practice is apt to be overlooked. And yet the information to be gained from its instillation in the eye is often of great value in estimating the integrity of the sympathetic system.

The supposed danger of producing glaucoma was founded on a series of five cases in which that disease was thought to be aggravated by the instillation of adrenaline.<sup>1</sup> Subsequent investigations have not confirmed the accusation. On the other hand, it has been advocated that adrenaline is not only harmless, but also that it is useful in glaucoma.

Grandclément in 1904<sup>2</sup> insisted that by the use of it glaucoma may be cured without operation if the disease has not advanced too far. Sydney Stephenson in 1908<sup>3</sup> recorded that adrenaline had shown itself of service in the treatment of glaucoma.

O. Loewi in 1907 proposed that the mydriatic response to epinephrine should be used as a diagnostic sign in Basedow's disease and in pancreatic insufficiency.

Coope<sup>4</sup> also supports the value of the response in the case of acute pancreatitis. According to Watanabe and Kato the sensitiveness appears to be somewhat increased in chronic nephritis.

Meltzer and Auer in 1903 pointed out that an increase of excitability to epinephrine occurred in degenerating structures of the car vessels.

Lewandowsky in 1898 showed that the mydriatic effect occurs after degeneration of the sympathetic.

Joseph demonstrated that epinephrine was to some extent counteracted by physostigmine; and Githens and Meltzer state that pituitary extract also counteracts the mydriasis in healthy animals.

The intraocular tension, according to Rupert, is first lowered and then increased.

Sollmann<sup>5</sup> records that this mydriatic effect occurs readily in frogs, but only in mammals under specially favourable conditions.

The mydriatic response in healthy frogs is especially strong, and may, it is said by Meltzer and Auer, be produced by systemic application, in extremely diluted solution, of adrenaline (1 in 100,000).

Post<sup>6</sup> has noticed dilatation of the pupil after instillation of adrenaline in cases of glaucoma and keratitis.

H. Straub in 1919 found that mydriasis occurred if the excitability of the sympathetic is increased as in Graves's disease and in acute pancreatitis. Later it was found that mydriasis occurs in all types of hyperaemia. The sensitiveness is also increased in chronic nephritis.

A mydriatic response may be obtained a few days after excision of the superior cervical ganglion. In many of these cases the mydriasis was accompanied by other evidences of ocular stimulation, such as separation of the lids, and protrusion of the eyeball.

W. H. Schultz records that in mammalia mydriasis only follows after large doses given intravenously; and adds that mydriasis may be obtained if the oculomotor tone is low, with weak illumination.

In man the effect is only invoked in exceptional circumstances, and then it usually signifies a lesion which involves the sympathetic. Straub states that it may occur if absorption is hastened by conjunctivitis.

The signification of a dilated pupil in irritation of the cervical sympathetic from wounds or growths is well known, but that dilatation can sometimes be produced by adrenaline in such diseases as acute pancreatitis and exophthalmic goitre is apt to be overlooked. Given a normal sympathetic system the power of adrenaline over the iris in man is null.

This drug, so frequently used by ophthalmic surgeons, should not be banned from the arsenal of the general physician. I have never seen any ill effects following its

use as a test, nor can I find any reports of cases in which trouble ensued.

Foster Moore,<sup>7</sup> quoting from do Schweinitz, writes: "Instillation of adrenaline, ordinarily inactive in causing dilatation of the pupil, becomes exceedingly active when the sympathetic is cut, or the superior ganglion is removed."

In conclusion it is to be noted that the response does not always occur in the numerous diseases mentioned; and therefore, while a positive reaction is valuable, a negative one does not exclude the suspected disease.

**Method of Application.**—One or two drops of a solution of chloride of adrenaline (1 in 1,000) are dropped into one eye, the other being reserved for comparison. The light should be subdued, as a glare is likely to impede dilatation. The conjunctiva will immediately blanch. If there is no dilatation of the pupil in ten minutes the instillation should be repeated. A dropper that has once been used for atropine should never be employed.

## THE 1927 EPIDEMIC OF DENGUE IN EGYPT.

BY

H. KAMAL, M.B., B.S., M.R.C.S., L.R.C.P.,  
GOVERNMENT FEVER HOSPITAL, CAIRO, EGYPT.

FOR several years Egypt was practically free from dengue; the last epidemic, prior to that here recorded, occurred in 1906-7 at Port Said and the Suez Canal zone. Last year, however, a sudden epidemic affected the whole country from the shores of the Mediterranean to the extreme south of Upper Egypt, preceded by equally sudden climatic changes. Thunder-storms, winds, and rains swept the whole country, and were followed by the appearance of dengue and other afflictions, such as the invasion of the Nile Valley by locusts, which constituted a very serious danger to agriculture. The epidemic started at the end of September; daily admissions of 30 or 40 cases of dengue were ward in the Government Fever Hospital, Cairo, while thousands of patients were attacked in the town with remarkable rapidity. Groups of policemen on duty in certain streets were attacked as a whole.

Thanks to the experiments organized by the Medical Departmental Research Board of the U.S.A. Army and others, we now know that a patient with dengue fever can infect *Aedes aegypti* (*Stegomyia fasciata*) during, at any rate, the first three days of his illness. The dengue virus appears to remain in the infected mosquito for about eleven days before the mosquito can transmit it to non-immunes, and the infected mosquitos continue to propagate the disease probably throughout the remainder of their lives.<sup>1</sup>

The *Philippine Journal of Science* published in 1926 most important information concerning the insect vector of dengue. It was proved that the vector is *Aedes aegypti* (*Stegomyia fasciata*) and not *Culex quinquefasciatus* (*C. fatigans*). It was also proved that a dengue patient might infect mosquitos during a period from a few hours before the first symptoms appear to the end of the second day of the disease, and possibly, though with less certainty, for another twenty-four hours or so, after which mosquito infection fails.<sup>2</sup>

The virus of dengue is at one stage, at least, an ultra-microscopic filterable one, and is present in the patients' peripheral circulation up to the third day of illness. It is also transmitted by blood or filtrate to non-immunes. The piropasma-like organism of Graham is probably an artefact. The incubation period is usually from four to seven days.

CHART 1.—Abortive type. Duration of illness before admission one day.

The mortality of this epidemic in Egypt was nil and the immunity variable. The following were the chief characteristics of the epidemic.

#### Symptoms and Signs.

Prodromal symptoms were observed in many cases, headache, malaise, and anorexia being the chief complaints. The onset was usually sudden. The patient while on

and lasted from a few hours to one week. It was either morbilliform, scarlatiniform, or petechial (like that of relapsing fever). When it belonged to the first two types it was not so bright. Over the extensor surfaces of the legs and forearms it was decidedly more pinkish. The rash appeared first on the dorsal aspects of the forearms and legs, then on the face, neck, chest, trunk, and upper and lower extremities (including palms and soles), but it was some-

CHART 3.—Intermittent type. Duration of illness before admission two days.

CHART 4.—Intermittent type. Duration of illness before admission three days.

duty developed high fever, preceded at times by rigors; he suffered from severe frontal headache, vomiting, and excruciating pain in the lumbo-sacral region, and over the joints of both limbs. Some patients became unconscious and remained so for a period ranging from a few hours to two days. Many were semi-conscious and drowsy; others were mentally and physically depressed, although their temperature was not high. The face was usually congested and sometimes swollen; the eyes appeared sleepy and photophobia was frequent.

The fever lasted from three to seven days, and was

times absent on the trunk. Desquamation was not the rule, but when it occurred it was of the branny type, accompanied by severe itching, and lasted for a few weeks. This rash is the most characteristic feature of the disease.

**Circulatory Symptoms.**—Precordial distress was noticed in a few cases. No heart lesion could be traced to dengue. Haematemesis, haematuria, and haemoptysis were rare. The pulse was usually slow throughout the disease, but more so towards the end of the fever, ninety beats being the average number per minute, with a temperature of 39° C., and fifty beats when convalescence started. There

CHART 5.—Remittent or saddle-back type. Duration of illness before admission one day.

CHART 6.—Remittent or saddle-back type. Duration of illness before admission one day.

CHART 7.—Remittent or saddle-back type. Duration of illness before admission two days.

usually of the saddle-back type. Very rarely patients were afebrile throughout the disease, and such were, therefore, a constant menace as potential spreaders of the malady. The following were the types of pyrexia noticed:

1. Abortive type in which pyrexia lasted from one to three days (Chart 1).
2. Intermittent type in which pyrexia lasted usually for seven days; the intermissions were sometimes separated by a period of normal temperature for one or two days (Charts 2-4).
3. Saddle-back type or remittent temperature (Charts 5-7).
4. Continuous type with febrile plateau (Chart 8).
5. Long type in which fever continued for ten to fifteen days (Chart 9).

The degree of fever was in no relation to the severity of the attack. High temperatures were sometimes accompanied by mild symptoms, and vice versa. The onset of fever and its decline were both by crisis; rarely the pyrexia ended by lysis. The fall of fever was accompanied by various phenomena, of which the chief were diarrhoea, dysenteric stools, epi-taxis, haematemesis, haematuria, heart failure, and, rarely, syncope.

**The Rash.**—The initial rash, which was nothing more than a flushing of the face and sides of neck and chest, was rather common. It appeared usually on the first day, and lasted from one hour to three days; it was frequently accompanied by inflammation of the throat. The secondary rash appeared about the fifth or sixth day of the illness,

have been cases where the pulse was rapid at first (120 per minute), but most of these ended in bradycardia. Cultures of the virus from the patients' blood were not successful at our laboratory. Examination of the blood showed an average leucopenia of 4,000 to 5,000 per c.mm. as a constant feature. This decrease in the number of leucocytes affected the polymorphonuclears most. A relative increase of eosinophilia and large lymphocytes was also noticed.

Except for the occasional congestion of the nose, throat, and larynx, the respiratory complications were rare. Pulmonary congestion was only seen in a very few cases.

No enlargement of the lymphatic glands was noticed, although it is mentioned that in some epidemics a considerable proportion of patients develop enlarged glands.

The pains were mostly muscular in origin, and therefore aggravated on contraction of the affected muscles. Nearly all muscles were affected, the most common being the ocular, iliopsoas, quadriceps, biceps brachialis, intercostals, and supra-, infra-, and sub-scapular muscles. The degree of pain varied from slight aching to excruciating pains which morphine alone could alleviate. There were no joint lesions. Headache was a prominent symptom in this epidemic; in one instance it lasted over seven days, during which the patient could neither sleep nor obtain ease without drugs.

**Gastro-intestinal Symptoms.**—Fetid breath was noted in

CHART 8.—Continuous type. Duration of illness before admission one day.

CHART 9.—Long type. One day ill before admission.

a few cases. The tongue was nearly always coated at the dorsum and red at the margins. Tonsillitis and pharyngitis were fairly common. No paratuberculosis was met with. Nausea and vomiting were usual at the commencement, but rarely persisted throughout the disease. Constipation was the rule, and was followed by diarrhoea at the terminal crisis. Dysenteric symptoms were present in a few cases throughout the malady. No changes were observed in liver or spleen that could be attributed to dengue.

**Urinary System.**—Albuminuria was common but transient. One case of acute nephritis was reported. Chronic kidney disease is likely to end by uraemia as the result of an attack of dengue. Diabetic patients when attacked sometimes developed a fatal coma, even during convalescence. Epididymitis, orchitis, cystitis, etc., were not met with.

**Complications.**—These were rare. Those met with were: pharyngitis, rhinitis, gastritis, enteritis, nephritis, and thrombosis.

**Sequelae.**—Itching of body, irritation of palms and soles, mental depression, vertigo, motor paresis, peripheral neuritis, staccato speech.

Children were just as liable to be attacked by dengue as adults. Males and females were affected equally. No deaths occurred among children.

Convalescence may be short or long—one day to three months. Patients lose weight, and usually suffer from mental depression, debility, loss of appetite, bradycardia, migraine, and neuritis. Relapses are rare.

#### Diagnosis.

In this season (December) in Egypt dengue has to be diagnosed from the following diseases:

(a) Malaria: by examination of blood films, size of spleen and liver, time incidence of febrile attacks, and rapid pulse.

(b) Measles: starts less suddenly; presence of Koplik's spots, coryza, absence of pains, rapid pulse, and deep red rash.

(c) Influenza: is usually accompanied by respiratory involvement, rapid pulse, and absence of rash.

(d) Scarlet fever: diagnosed by presence of throat symptoms, rash, rapid pulse, absence of pains, and blood examination.

(e) Small-pox: in the first three days of dengue it is very difficult to differentiate it from small-pox. Later on the course of the malady soon manifests its nature. History of vaccination may help.

(f) Articular rheumatism: diagnosed by history of malady, presence of acid sweats, and joint lesions.

The treatment is symptomatic and prophylaxis involves antimosquito measures.

## DUPLICATION OF THE SPINAL CORD.

BY

F. PARKES WEBER, M.A., M.D., F.R.C.P.

AN excellent review of the known cases of partial doubling of the spinal cord was written in 1906 by A. Bruce, Stuart McDonald, and J. H. H. Pirie<sup>1</sup>; for the reference to it I am indebted to Dr. Kimmer Wilson. Nevertheless, the following case perhaps deserves a note.

The patient, a well-developed man, aged 51, was admitted to hospital on March 29th, 1928, with a spastic parietic ataxic gait and signs suggesting combined degeneration of the spinal cord. He had a pale, sallow face; the liver was considerably enlarged, and the spleen could be felt, reaching just below the ribs. The gastric contents after a test breakfast contained no free hydrochloric acid. The erythrocyte count was 3,332,000 and the haemoglobin was 70 per cent. The white cells were 17,800 (polymorphonuclears 74 per cent., lymphocytes 17 per cent., monocytes 9 per cent.). The Wassermann reaction was negative. There was a little irregular pyrexia, and apparently a remnant of pneumonia in the middle part of the right lung, which possibly explained the presence of a polymorphonuclear leucocytosis. According to the history obtained the patient had noticed something wrong with his feet in August, 1927, and since December, 1927, he had been taking an "ox-liver juice" twice daily for anaemia. The result of the ox-liver treatment was said to have been good, till weakness in his legs developed ten days before admission.

In the hospital, in spite of liver diet, etc., the weakness in the legs increased, paradoxical incontinence of urine and cystitis, with bedsores, developed, and death occurred on April 26th.

The necropsy and microscopical examination confirmed the diagnosis of combined degeneration of the spinal cord; but during the macroscopical examination it was noticed that, close along the left side of the lower part of the spinal cord, there was another cord-like body of the same consistence as the cord, but smaller (about 1 cm. in diameter) and without nerve roots proceeding from it. Its upper end arose from the substance of the cord by a base somewhat over 1 cm. in diameter, the uppermost part of its insertion being 7½ cm. above the terminal point of the conus terminalis. At its lower (free) end it tapered to a point, which was 1½ cm. above the lower end of the conus terminalis.

Transverse microscopical sections of this macroscopically tumour-like appendage of the spinal cord showed it to be quite obviously a fairly well-developed duplicate cord with a central canal, etc. This was kindly confirmed by Dr. J. G. Greenfield, who also confirmed the fact that the duplicate cord showed well-marked signs of combined degeneration, just as did the main spinal cord (from which the cauda equina arose).

When I saw the long polypoid tumour-like appendage lying along the left side of the lower portion of the spinal cord, I at first thought that I had made a mistake in the diagnosis, and that the patient's paraplegia, etc., might have been due to a tumour; but microscopical examination, as already stated, completely cleared up the nature of the tumour-like structure, proving it to be a congenital abnormality, a doubling of the lower part of the spinal cord. One may wonder whether in this case lipiodol would have been partially arrested at the site of origin of the duplicate cord had it been used to ascertain the site of a possible tumour.

## THE ETIOLOGY OF MONGOLISM;

WITH A CASE OF MONGOL TWIN.

BY

HUBERT ARMSTRONG, M.D. VICT. AND LIVERP.,  
SENIOR HONORARY PHYSICIAN, ROYAL LIVERPOOL CHILDREN'S HOSPITAL.

THE occurrence recently, in my hospital practice, of a case of twins, one of whom was a Mongolian imbecile, the other not, stimulated investigation into the etiology of that distressing and increasingly common type of mental deficiency. But the ultimate cause of Mongolism is, I suppose, as yet unknown, nor can I find much to elucidate it.

The peculiar history so often obtained—namely, that the child is either the first of a very young mother, or, as often happens, is born many years after the previous one, and most frequently of a mother nearing the menopause—warrants the assumption that this developmental error is in some way due to immaturity or exhaustion of her procreative powers.<sup>1</sup> At what stage in the development of the ovum or foetus this makes itself felt has been the subject of a good deal of argument.

The problem is this: Is Mongolism inherent in the unfertilized ovum, or is it acquired after fertilization? A third proposition might be that Mongolism is imparted to the ovum in fertilization, were it not that the history appears to point to the maternal factor so constantly. As a generality it may be assumed that parents are approximately the same age, the father being on the average a year or two the elder. This would make the odds even as between the two parents, were it not that there is no evidence, known to me, that the children of elderly men tend to Mongolism otherwise than when their wives are approaching the menopause. Nevertheless, this possible factor cannot be entirely brushed aside without consideration.

An argument in favour of the post-fertilization embryonic theory is that Mongols are so often the subjects of other congenital abnormalities. Of these the commonest are malformations of the heart, followed a long way behind by congenital cataract—defects which obviously cannot

occur till embryonic development has proceeded far enough to start the formation of the organs implicated; and the heart, for example, is perfectly formed, though in miniature, by the end of the seventh week after conception.<sup>2</sup> By analogy it is argued that similarly the Mongolian characteristics (which are in effect congenital malformations) take their origin in the embryonic<sup>3</sup> period of the first six weeks of intrauterine life. This may be countered by the argument that an ovum already the subject of an inherent defect (of a nature which is wonderfully true to type) is more likely to go wrong in other directions than one which is not.

David M. Greig, in a recent long and erudite article,<sup>4</sup> favours a theory that Mongolism is a defect of foetal growth, though he concludes that this must have started in the embryonic period mentioned already. He bases on his minute and fully recorded observations on three Mongolian skulls the deduction that Mongolism "seems rather to be a defect in growth (foetal) than a defect in development (embryonic)." He states that "the main defect in the skull is want of growth of the facial bones, chiefly the maxillae and of the alveolar processes anteriorly," with various consequences to the adjacent bones, into which I need not enter. As an interesting aside, however, it may be mentioned that although obliquity of the palpebral fissures and nearness of the eyes are characteristic of the Mongolian facies, there was an obliquity of the superciliary margins in these skulls, nor any undue approximation of the bony orbits. With regard to the reported arrest of development of the skull base he goes on to say: "Deficiency of the anterior wall of the acoustic meatus, imperfect closure of the foramen ovale and foramen spinosum, flatness of the occipital condyles, and in the youngest skull an indication of the component parts of the occipital bone, are evidences of delayed development, but are not features which have interfered with the growth or size of the skull-base. If any arrest of development has occurred it is in the brain, not in the bones..."; and later, "Before the age of 16 the growth of the Mongol's brain has ceased." He states as his final opinion that "even from the skull alone there seems evidence that development normally begun has mapped out all structures and features in the embryo, but has failed to lead them to perfection during foetal growth." Pointing out that the first appearance of ossification in the skull appears in the maxillae on the thirty-ninth day, followed by the premaxilla three days later, and the nasal bones on the fifty-seventh day, he says: "Obviously it is during this period that the departure from normal growth shows itself, and this failure in the bones is accompanied or followed by defective growth elsewhere, notably in the nervous system."

For myself, though open to conviction, I believe the maternal influence, which appears to be almost undeniable, and whatever it may be, is exercised upon the ovum during its maturation, and therefore before fertilization has followed and segmentation started.

The chief argument in favour of this theory is the occasional occurrence of twins one of which is Mongol and the other not. This proves beyond a doubt that no maternal influence is present after embryonic development has begun; or that if there be any such influence it is selective in a manner highly improbable, though I recognize this argument is a two-edged sword. It has no bearing on the question of responsibility as between the parents, for obviously if one ovum can be inherently Mongol and the other not so, the same should hold good of the male elements. Known cases of twins both of which were Mongols are so rare—only some three in number—and their original records so inaccessible that although they were of the same sex complete proof that they resulted from uniovular pregnancies is wanting, but the assumption that it was so is warranted. There are also three cases on record where the twins were of the same sex, one being Mongol; but there is equally no proof that these were uniovular pregnancies. But on no occasion has it yet been recorded that twins of different sex were both Mongols, which is in accordance with the mathematical probabilities under this theory. Though the theory does not prohibit the possibility of binovular twins being Mongols it must be remembered that, apart from the six twin cases above

mentioned, and admitting the fact that the Mongol is often the last pregnancy, more than one Mongol in a family is almost, if not quite, unknown. But we are still as far as ever from solving the problem of the malign influence dooming the ovum to Mongolism, and the corollary of prevention.

In January, 1923, Halbertsma of Haarlem<sup>5</sup> collected fifteen cases of twin pregnancies of which one twin was Mongol and the other normal. Occasional additions to this list have since been made, and to these I am able to add another instance.

On December 23rd, 1926, C. F., aged 4 months, was brought to the Royal Liverpool Children's Hospital because "he was not coming on." He was one of twins, the other being a girl, who, at my request, was brought on a subsequent occasion for comparison, and proved to be a normal and healthy child, though small for her age. The boy had the typical Mongolian cranial attributes and facial appearance, with the other characteristics of the Mongolian imbecile, including the loud bruit and the cyanosis of a congenital heart lesion. This child further complied with the frequent Mongolian history by dying of measles, contracted when he was 14 months old. The sister recovered.

## A CASE OF PRIMARY ACTINOMYCOSIS OF THE LUNG.

BY

HERBERT SHARPE, M.R.C.S., L.R.C.P.,  
MEDICAL SUPERINTENDENT, WARE PARK SANATORIUM, HERTS.

OWING to the fact that patients admitted to tuberculosis sanatoriums have mostly been diagnosed before admission one is apt to be biased in favour of tuberculous infection and to take for granted that the diagnosis is correct, instead of approaching the case with an open mind. During the course of the illness of a certain patient one or two complications ensued which raised some doubt as to the diagnosis of pulmonary tuberculosis being correct; hence I have thought it worth while to publish an account of the case.

**Previous History.**—Up to the age of 18 the patient had lived in South Africa, where, after leaving school, he was an apprentice in a lithography works. He came to England for a few months' holiday, and then went to Australia with a friend to search for gold. After a few months of unsuccessful prospecting they both worked on a ranch, sheep farming, for about eighteen months or two years. The patient then joined the army soon after the outbreak of war. He was sent to England and thence to France, where he was "gassed" in March, 1918; his war service amounted in all to three and three-quarter years when he was demobilized. He then joined a Government tug boat and remained at this work for four years. He returned to England, and after three months' holiday worked as a bricklayer for five months, later returning to his original work as a lithographer. His health gradually deteriorated, but he remained at work until June, 1927, when he complained of acute pain in the left side, anorexia, and loss of weight. He was first seen by a tuberculosis officer in October of that year, who, after having carefully watched the temperature (99.2°–102°) for a few days diagnosed the case as anaemia and pleurisy with effusion, and recommended sanatorium treatment. The sputum had been examined a month previously, with a negative result. There was no significant family history and no previous illness of importance.

**Condition on Admission.**—The patient was admitted to the Hertfordshire County Sanatorium on October 24th, 1927. He gave his age as 35, was very anaemic, and looked exceedingly ill. He had lost about 2½ st. in weight, and had not had a good night's rest for a fortnight. His temperature was 100° F., pulse 118, and respirations 24. He complained of pain extending from the right shoulder down the outer side of the arm as far as the elbow, but since no definite lesion could be found to cause the pain, it was attributed to neuritis. On examination of the chest the left side was found to be dull on percussion, the dullness being most marked at the left base posteriorly. There was also slight impairment of the note at the right apex. There were moist crepitations throughout the left side, and in addition diminished breath sounds at the base behind with amphoric breathing—signs compatible with pleurisy with a small effusion. His liver was palpable and slightly tender; the abdomen otherwise revealed no abnormalities. The urine contained no albumin or sugar; the specific gravity was 1020 and the reaction acid.

**Subsequent History.**—The pain down his right arm was treated with methyl salicylate and a neuralgia mixture was given. Nephthalin 20m was ordered, and the next day he appeared to

be somewhat easier. Between November 1st and December 24th, ten abscesses developed in various parts of the body, most of which were aspirated or incised under novocain. On two occasions pus was sent for bacteriological examination and inoculation of a guinea-pig requested. The first report was as follows: "Thick grumous blood-stained material. Microscopically non-cellular apart from red blood corpuscles. Tubercle bacilli could not be found." No other organisms found. The second report stated: "Microscopically it is essentially structureless, only a few cell-outlines being seen. Tubercle bacilli could not be found either by direct films or by concentration methods. No other micro-organisms were found on microscopic examination and cultures remained sterile. Animal inoculation of the material for tubercle bacilli is being proceeded with."

During this time the patient's temperature and pulse remained about the same, his general condition seemed to be improving, but the signs in his chest were unaltered. The Wassermann reaction was negative, as also were blood tests for typhoid and paratyphoid infections. On December 12th his temperature began to subside, it being 98.4° F. in the morning and 100° F. in the evening; between December 18th and 22nd it remained between 97.2° F. and 98.5° F. On December 23rd it became subnormal, and remained so until his death six days later. The pulse rate, on the other hand, never dropped below 100, ranging between 100 and 120, with respirations constant at 24.

Special features as regards the case from a differential diagnostic point of view were: (1) all the abscesses developed very quickly; (2) they caused great pain; (3) after the first had been incised the pus, which was quite innocuous, became so fetid that the patient had to be removed from the ward into a separate shelter; (4) the relief experienced after incision and aspiration was very considerable.

A post-mortem examination was performed on December 30th by Dr. G. H. Pringle and myself, and the following observations were made.

There were adhesions on the left side between the left lung and chest wall, becoming denser towards the base. A large abscess was found in the base of the left lung, which showed collapse. Both lobes on the left side and the two upper lobes on the right contained numerous small nodules, which proved to be abscesses. The heart was small, and there was an ounce of greenish fluid in the pericardial sac. There was slight atheroma of the aorta, a little thickening around the pulmonary orifice, and a small abscess in the wall of the left ventricle. Other abscesses were found in the following organs: two in the liver, which was congested and fibrous; one in the left kidney, round which were adhesions; a perinephric abscess, which communicated with the one in the lower part of the left lung through an opening in the diaphragm (the right kidney was normal); and one in the spleen, which was slightly enlarged and friable. There were a few small flattened greyish nodules in the mesentery, but no peritoneal adhesions.

Portions of the abscess tissues from the liver, lungs, and heart were examined histologically, and the organism responsible for the condition was found to be the actinomycetes. The tissue was remarkable in showing a large number of granules, which is rare in human actinomycosis. The guinea-pigs inoculated showed no signs of tuberculous infection, and the pus was presumably, therefore, free from tubercle bacilli.

My thanks are due to Dr. H. Hyslop Thomson, county medical officer of health, for permission to publish this account, and for his assistance, also to Dr. G. H. Pringle for his help in the investigation.

## AN ADJUSTABLE BOARD-BED.

BY

LEONARD HEARN, M.B., B.S. DURN,

LATE RESIDENT MEDICAL OFFICER, HULL TUBERCULOSIS SANATORIUM,  
COTTINGHAM, E. YORKS.

TUBERCULOUS disease of the hip is unfortunately only too often met with for the first time when the condition is well established and the joint is more or less fixed, with the limb in a bad position of adduction, inward rotation and flexion, and usually a certain amount of shortening. The bed splint to be described has been used with excellent results; it is designed to correct the deformity very gradually and obtain the desired position, with a quiescent condition, before the limb is put up in a plaster splint.

All tuberculous lesions improve as the general condition of the patient grows better, and these cases should be placed on the open verandah day and night in all seasons. This bed splint enables the patients to be treated under open-air conditions; they are really only confined to bed like pyrexial pulmonary cases, and enjoy a maximum amount of comfort, thus benefiting both morally and physically. Often in cases of tuberculous disease of the hip-joint the limb is fixed in plaster, or in a Thomas's hip

splint, in a more or less good position, but this unfortunately may entail a compensatory lordosis of the spine, with subsequent permanent deformity.

This apparatus is essentially a "board-bed," hinged in the middle so that the lower half supporting the legs may be raised or lowered at will by means of a support on a ratchet similar to the method of fixing an ordinary deck chair. Six boards form a box frame for retaining the patient in position, and these swivel from the centre line

of the bed; they are kept in position by means of pegs in rows of holes at the foot and head. The lower end of the frame can be extended to fit any length of patient, and the boards being 3½ to 4 inches high, cradles are unnecessary. Pulleys adjusted by means of thumb-screws carry the extension weights, and move to any position on the lower edge of the frame.

At the commencement of treatment the spine is placed in its natural position, with the limbs raised and with a suitable extension weight applied, the affected joint is gradually abducted, and the leg is lowered as required, the position of the spine not being allowed to vary, so that lordosis is never present.

The case shown is a typical tuberculous arthritis of the left hip; this joint was held in a bad position of flexion and adduction, with two inches of shortening. There were present also all the symptoms of active disease, such as pain, heat, and pyrexia.

The first photograph demonstrates the amount of compensatory lordosis which was present when the affected

leg was kept flat to correspond with the sound leg; this is the position in which so many limbs, after abduction and external rotation, are finally fixed in a plaster-of-Paris or

Thomas's splint. The second photograph shows the patient in position at the commencement of treatment, with the spine in normal position. In the third the corrected limb

is seen after use of the board-bed and ready to be put up in plaster-of-Paris, after having been submitted to very gradual lowering and extension, dependent on the position of the spine.

This patient was never off an open verandah. His general condition is excellent in every way; there is now no pain or tenderness, and the pulse and temperature are quite normal.

The apparatus is simple to use; it can be quickly adjusted in any direction by the medical officer from time to time, and it renders nursing easy. Thus a bed-pan is used by merely hooking up the extension weights and sliding the patient up the bed; he sits back into position when the pan is removed, and the weights again hang free. The splint will lie on any ordinary bed and fit any patient, child or adult. Cradles, which cause draught and discomfort, are rendered unnecessary.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### FRACTURED BASE OF THE SKULL FOLLOWED BY ACUTE MASTOID DISEASE: RECOVERY.

ACUTE mastoid disease is an unusual sequel of fractured base, and the following details of such a case seem to be worthy of record, especially since almost complete recovery followed operative treatment.

While hunting on February 1st, 1926, a lady was thrown from her horse, which rolled over her. She was unconscious on being picked up, and was bleeding from both ears and from the nose. Both clavicles were broken, and there were injuries to some ribs. She was completely unconscious for twelve hours, and only partially conscious for the next four days. It was noticed that she had right facial paralysis, and on recovering consciousness more completely it was found that she had paralysis of the right sixth nerve, causing double vision.

The external auditory canals were kept clean by swabbing with 1 in 20 carbolic solution. On the eighth day there was earache on the right side; no discharge appeared from both ears on the tenth day, and her temperature rose to 100° F. On the twelfth day she complained of earache on the left side. There was considerable swelling around the upper part of the right mastoid, extending above the ear into the temporal region, and in front to just below the zygoma. This had appeared very shortly after the accident. There was a free discharge of pus from this ear, and when the canal was cleaned out it was found to be torn across close to the membrane, which could not be seen properly owing to narrowing of the canal. The left canal contained some dried blood and discharge, but no perforation could be seen in the membrane, which was not reddened. Both mastoids were very tender to pressure, and this had always been the case since she recovered consciousness. Air conduction was diminished, but bone conduction was normal. The temperature was 100.6° F., and the pulse 92. She answered questions intelligently, but when not spoken to lay in a drowsy condition with her eyes closed. The following day the pulse and temperature were normal, and remained so for thirty-six hours, when the temperature again rose to 100° F., the pulse being 88. On the sixteenth day she had "neuralgic" pain in her right ear and mastoid, and there was some increase of the swelling in this region, the ear being pushed forward; the temperature was 101.6° F., and the pulse 100. The left ear was again discharging slightly, and it was obvious that the right mastoid was infected.

**First Operation.**—The usual incision was made, and a fracture could be felt; on retracting the tissues it was seen to run upwards and backwards over the mastoid from the lower part of the bony meatus, and there was some gaping between the edges. A small three-sided trepan was used to make a hole in the bone; this was replaced by larger-sized trepan, and by gentle use of burrs and forceps the hole was enlarged. Some pus was found in the cells just over the antrum, and on opening the latter there was a gush of pus. The surrounding cells were removed, but no attempt was made at a formal operation. The middle ear was washed out through the auditus, and the cavity in the bone, after being mopped out with spirit, was bipped and lightly packed with bipped gauze. The perforation in the left membrane was enlarged. The time of operation was 11 p.m.

The next morning at 8 o'clock the temperature was 98.4° F., pulse 86, but by 10.30 the temperature had risen to 103° F., pulse 132; the breathing was sighing, and she appeared very ill indeed. There were no meningeal or labyrinthine symptoms, but the question of a commencing lateral sinus infection or a perisinous abscess had to be considered, as had also a deep infection of the tissues in the swollen area or in the line of the fracture. By the evening the temperature had dropped to 100.6° F., pulse 104, and she was in much better condition. The temperature remained below 100° F. till the twentieth day, when it again rose to 101.4° F. at 8 a.m., and 101.4° F. at 4 p.m. the next day. The swelling in the temporal and zygomatic region became more marked, the right eyelid was swollen, and the eye was nearly closed; some oedema and reddening over the forehead appeared, extending to the left side.

**Second Operation.**—An incision was made in the temporal region, and the temporal, zygomatic, and sphenomaxillary regions were explored with a very large-bore needle, but no pus was found. A further free incision in the temporal region was made and fomentations were applied. The next day the temperature again

shot up to 103° F., but dropped to 98° F. by 8 p.m.; after this convalescence was rapid and uneventful.

The facial paralysis had almost entirely cleared up by the beginning of May, when she was able to take walks of two to four miles, but the diplopia persisted for about another month. Some granulations had to be curetted out of the right canal. The discharge soon cleared up. As soon as the membranes were soundly healed gentle politizerization was used, and this was later supplemented by massage. From time to time all treatment was stopped for a week to ten days.

The hearing in both ears is now practically normal; there is no narrowing of the right external auditory canal. The patient is again leading her normal life, and has resumed hunting. Headaches, or other sequelae, are absent.

#### PNEUMONIA WITH ACUTE ABDOMINAL SYMPTOMS AND MULTIPLE ABSCESES.

THE simulation by pneumonia of an acute abdominal condition is not very uncommon, but the following case presents some unusual features and seems, therefore, to be worthy of record.

A young lascar was admitted to the British Cottage Hospital at Algiers, on February 16th, complaining of anorexia and great pain below the liver running down the right side of the abdomen. On palpation muscular contraction prevented exploration of the subjacent viscera, but no tympanites was present and the abdominal respiration was unimpeded. The temperature was 101°. The bowels were loose, but nothing abnormal was found in the faeces; it was decided that there was no necessity for immediate intervention.

He began to cough considerably two days after admission, and examination showed dullness over the upper lobe of the right lung extending into the axilla. The sputum was not particularly viscid and did not present the characteristic colour of pneumonic expectoration. Puncture of the pleura over the dull area brought away only a few drops of blood-stained fluid rich in pneumococci. At the back respiration at the upper part of the lung was blowing and there was pectoriloquy. The crisis occurred on February 25th, when the temperature returned to normal and did not subsequently rise.

The patient improved and began to take food readily, but he complained of pain in the back of the neck on movement in any direction. Nothing abnormal could be made out in that situation by palpation, but there may have been pneumococcal arthritis; Kernig's sign was absent. Then swellings appeared on the arms—one on the outer aspect of the right forearm and two on the outer aspect of the left arm, the uppermost just below the deltoid. The swellings ranged in size from a filbert to a walnut, and fluctuated freely. On being opened they gave exit to creamy pus containing a pure culture of pneumococci. The patient was given three intravenous injections of antipneumococcal vaccine; these were not followed by any rise of temperature, but he became noisy and had to be placed in a separate ward. He ultimately made a good recovery, the abdominal symptoms having cleared up spontaneously in the course of four or five days; the stiffness of the neck subsided gradually.

Judging from the literature of the subject the prognosis in cases of pneumococcaemia before the introduction of vaccines was extremely grave, but this is my second case in which the use of an antipneumococcal vaccine appears to have exerted a favourable influence. I reported a case of pneumococcal polyarthritis in the *British Medical Journal* of September 13th, 1924 (p. 455).

The interesting feature in the present instance is the patient's admission as an acute abdominal case. The fact that pneumonia may simulate appendicitis has long been known, and this is particularly the case in infantile pneumonia. Daussey, in 1913, collected notes of a number of such cases for his Paris thesis. He points out that while some patients treated for pneumonia were found after death to have had appendicitis, on other occasions patients operated upon for appendicitis were found after death to have had pneumonia. He concluded that pneumonia, especially in children, might be accompanied by an abdominal syndrome resembling that of appendicitis. This is not due to an abnormal localization of the pneumococcus; it is quite possible, of course, for the two affections to coexist, and it is obvious that an attack of appendicitis may predispose to an attack of pneumonia. He divides these cases into two main groups—namely, (1) those in which the pneumonia soon dominates the scene while the abdominal symptoms spontaneously clear up, and (2) those in which the appendicitis becomes and remains the principal feature, the pneumonia only being recognized later on. The cases belonging to the first group are usually mild, but the prognosis is not so good in the second. The moral to be drawn from his observations is that in

practice we ought to look after the appendix in our pneumonia patients and keep an eye on the lungs in cases of appendicitis.

Algiers.

ALFRED S. GUNB, M.D.

### PULMONARY SILICOSIS.

THE following case would appear to be worthy of record in view of the question of compensation that arises.

A stone borer, aged 42, had worked in a coal mine for twenty years; there was no history of any previous illness or a family history of disease. Before his employment in the mine he had worked in a quarry, boring with a pneumatic drill and blasting away the hard rock above the coal seam. I am told that this rock is so hard that no other method but explosive will suffice. Last August he complained of an irritable dry cough, which resembled a bark. There were no definite signs then in the lung, and a tuberculosis officer excluded this disease; the x-ray photograph showed mottling, but there was no wasting. In fact, the man said he felt quite fit, but the cough tired him out.

An examination by a laryngologist led to the suggestion of there being pressure on the recurrent laryngeal, with silicosis as the probable cause. The Wassermann reaction was negative. The patient was seen by the regional medical officer, who agreed with the diagnosis of silicosis. Several specimens of sputum were sent to the county bacteriologist with negative results. Dr. Ifor Davies saw the case and also diagnosed silicosis. Early this year the patient had an attack of acute bronchitis with signs of bronchiectasis; cardiac insufficiency and oedema supervened, ending in death. Four or five sputum examinations were made during the last month again for tubercle bacilli, but proved negative each time.

I do not think there is much doubt as to the diagnosis. The patient had been seen by six independent medical practitioners, who agreed as to the nature of the condition.

I am informed that silicosis is not on the schedule; consequently this man's widow and children receive nothing. Tenosynovitis and miners' heat come within the scope of the Workmen's Compensation Acts, when in my opinion a "damaged" lung is a condition with a much less problematic etiology. Compensation is paid should tuberculosis supervene in a previously damaged joint at work; why should it not be available if the lung is damaged through the hazard of occupation?

## Reports of Societies.

### THE INTESTINAL AMOEBAE OF MAN.

At the meeting of the Royal Society of Tropical Medicine and Hygiene on June 21st, with Professor J. W. W. STEPHENS in the chair, a paper on "The differentiation of the intestinal amoebae of man" was read by Professor E. BRUMPT, of the Laboratoire de Parasitologie, Faculté de Médecine, Paris.

Professor Brumpt said that English authors had been the first to demonstrate the frequency of occurrence of four-nucleated cysts of *Entamoeba* in individuals who had never been in tropical countries. These cysts had been considered as invariably identical with those of the real *E. dysenteriae*, discovered by Quincke and Roos in 1893, and it was upon this rather hasty identification that all writers had published their statistics. The statistics demonstrated the peculiar fact that four-nucleated cysts were encountered nearly as often in countries where amoebic dysentery was unknown as in those where it was extensive. It had yet to be explained why amoebae were pathogenic for man in one of four persons of the Philippines, one in ten or twenty in various parts of India and Indo-China, while in England, France, and Holland, where millions of cyst-spreaders existed, only a few cases occurred each year, and among those cases contagion from exotic carriers was usually demonstrable. In the speaker's estimation most statistics had been established on a false basis. Nearly all authors had considered all four-nucleated cysts as belonging to *E. dysenteriae*, but in fact these cysts were produced by three different *entamoebae*—namely, *E. dispar*, *E. hartmanni*, and *E. dysenteriae*, and in that order of frequency. *E. hartmanni* was a small amoeba, found in all parts of the world, and one which did not seem to be pathogenic for man. He thought it could be separated from *E. dysenteriae* by its morphological and biological characters. *E. dispar*, which

had been taken for *E. dysenteriae* in temperate countries—in England, for instance—was much more difficult to identify than *E. hartmanni*, for it differed from *E. dysenteriae* only in a negative character. It stood out from *E. dysenteriae* by its natural and experimental habitat, its geographical distribution (which extended beyond that of *E. dysenteriae*), by the way in which it fed in natural hosts and in culture, and by its pathogenic power. This amoeba, dwelling in the large intestine, lived probably on the surface of the epithelium without producing macroscopic lesions. It was incapable of producing liver abscess, though, like *E. hartmanni*, *E. dispar* probably gave rise, when numerous, to various slight digestive troubles. This parasite was widely spread among individuals who seemed to tolerate it quite well, while in *post-mortem* examination lesions of the gut caused by it had never been observed. Differentiation could be made by injection of the cysts into cats. When the agent was the dysenteric amoeba the cat died with the usual lesions; if it was *E. dispar* any infection produced was only mild. Professor Brumpt considered that the dysenteric infections reported during the war by Yoko and others as occurring among recruits who had never been out of England were infectious in which *E. dispar* and not *E. dysenteriae* was implicated. If amongst cyst-bearers—and there were several millions in England—only one or two cases of dysentery occurred each year, it was because these many cyst-bearers were infected with *E. dispar* and *E. hartmanni* and not with *E. dysenteriae*.

Professor Warrington Yorke said that Professor Brumpt had offered a very simple explanation of a puzzling phenomenon—namely, why a definite percentage of apparently healthy people should harbour a pathogenic organism, or what nutil that evening most of those present had believed to be such. Professor Brumpt had said that it was difficult to differentiate these species, *E. dispar* and *E. dysenteriae*, on their morphological characters, but the speaker confessed himself one who still clung to morphology as offering the soundest basis for classification. The onus of proof lay on those who stated that things which appeared to be the same were really different. With regard to the work which he and others had done in 1917 on recruits who had never left England, it was noteworthy that in at least two of these cases infections were produced in cats which were not to be distinguished from those resulting from similar experiments with the excreta of chronic dysenteries. In certain circumstances amoebic dysentery could be contracted in England in indigenous cases, and it was possible that if signs of amoebic dysentery among the population of temperate zones were sought for by skilled observers they would be found much more commonly than at present imagined. Why certain persons should harbour *E. dysenteriae* and exhibit no signs of the disease was not known, but the explanation might well be that before *E. dysenteriae* could produce any disease some additional factor was necessary, such as susceptibility of the alimentary canal. The researches of Adams and himself had shown that cysts of *E. dysenteriae* passed by different individuals, or by the same individual at different times, differed markedly in numbers passed in a day, the stage of development at which they were passed, and their viability as judged by cultural methods.

Dr. H. L. Duke instanced the parallel with regard to trypanosomes. The dualist view was that *T. rhodesiense* and *T. brucei* had very little to do with one another; a recent investigator had linked up *T. rhodesiense* and *T. gambiense* as the same species appearing under different guises, and *T. brucei* was regarded as a trypanosome which had no use for man. The unicists, of which he was one, regarded *T. rhodesiense* and *T. brucei* as very nearly allied, and he himself thought that *T. gambiense* was a variant of *T. brucei* which had become a specialized parasite of man, having been forced to utilize man as its final host owing to the decrease of game in the regions where man and the tsetse fly came into close contact. There was a parallel between the situation in the trypanosomes and as Professor Brumpt had sketched it in the amoebae. The speaker put forward the hypothesis that there was one polymorphic species of amoeba, a parasite of man, but differing in its adaptation to man in different circumstances, and that occasionally this adaptation broke down, resulting in dysentery.

Dr. GORDON THOMSON felt the subject to be extremely difficult because so many unknown factors in the transmission of amoebic dysentery were evidently at work. One important factor was the mass of infecting dose, which was probably negligible in a country like England, but in Egypt, where there were large numbers of flies, and where faeces were deposited all over the ground, it was very considerable.

Dr. C. M. WEXTON pointed out the embarrassment to clinicians should Professor Brumpt's view find acceptance. Hitherto, on the presence of four-nucleated cysts of the *histolytica* type being reported, the patient was put on emetine, but now the clinician would have to await a further verdict, to be tested on the cat, as to whether the agent was *E. dispar* (in which case the patient should be left alone) or *E. histolytica*. Dr. H. M. HASSCHEL, taking up this last remark, said that if Professor Brumpt stayed the routine rush to emetine he would have done a great deal of good, because it was quite clear that amoebic dysentery was not absolutely constituted or demonstrated merely by the fact that in the stool a four-nucleated cyst had been found. Dr. SIBBELAX spoke of experience in two tropical countries—Mexico and Central Africa. In both these countries there was a considerable frequency of amoebic dysentery, but liver abscess, which was exceedingly common in Mexico, was comparatively rare in Central Africa. One differentiating factor was perhaps flies, of which there were a large number in Mexico, but hardly any in the Congo, where dust was more likely to be the principal means of transmission.

Professor BURXER, in reply, spoke of the great difficulty in identifying species on a morphological basis alone. Morphology was in a state of evolution, and was not infallible. Indeed, it was sometimes not possible to distinguish morphologically between certain quite complicated organisms. With regard to the frequency of liver abscess among dysenteric individuals, this was generally, in white men, in the proportion of one in six, but racial factors came in, and it was possible that in Mexico there was a mixture of whites and Indians, which would alter the incidence.

### EDINBURGH OBSTETRICAL SOCIETY.

At a meeting of the Edinburgh Obstetrical Society held on June 13th, with the president, Dr. HAIG FERGUSON, in the chair, a paper by Professor W. STROGANOFF entitled "A plea for the treatment of eclampsia by the improved prophylactic method" was read by the secretary, Dr. DOUGLAS MILLER. The paper followed much the same lines as that communicated to the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on June 15th, and reported in the *British Medical Journal* of June 23rd (p. 1065).

#### *Treatment of Eclampsia.*

Professor Stroganoff began by giving statistics to show that eclampsia still remained a great menace to child-bearing women, and was accountable in Russia, the United States of America, and England for a maternal death rate of nearly 8,000 women and over 14,000 children every year in these countries alone. This mortality could, in his opinion, be greatly reduced by the adoption of his treatment. Twenty years ago, in a series of 360 cases of eclampsia, he reported a 6.6 per cent. maternal mortality and a 21.6 per cent. foetal mortality. This compared very favourably with all other treatments, where the mortality was usually over 20 per cent. During the last twenty years Professor Stroganoff had treated 300 further cases of eclampsia by his improved method, with a maternal death rate of 8. Of these, however, four patients arrived at the clinic moribund and two died from pneumonia and sepsis. In 40.3 per cent. of the 300 cases there was not a single convulsion after the beginning of treatment; in 44.4 per cent. there were from 1 to 3 seizures, and only in 15 per cent. were there more than three. In a large number of cases there was freedom from convulsions for twelve hours before delivery, 63.8 per cent. coming under that category. The mortality among children was a relatively small percentage, being only 16.8 per cent., but if premature children weighing less than 3,000 grams be excluded,

the foetal mortality is reduced to 6 per cent. There was not a single maternal death due to treatment, whereas in the old days, when accouchement forcé was the method of treatment, 4 per cent. of the mothers died as the result of the operation. There was a relatively small number of operative deliveries, and rapid recovery of the patient was general. Of late, Professor Stroganoff had visited clinics in Vienna, Berlin, and London, but the number of eclamptic cases seen in these cities were few and not up to expectation. These visits, however, had not been in vain, as they taught the value of the prophylactic method, and there had been a definite improvement in the mortality rate in the various clinics. In cases at a distance the telephone could be used to instruct the medical attendant as to the treatment to be adopted. This had been done in one hospital where 176 cases of eclampsia had been so treated. In his last series of 85 cases of eclampsia treated over the telephone there was only 3.6 per cent. mortality. Professor Stroganoff deprecated the operation of Caesarean section in the treatment of eclampsia, as such a treatment not infrequently contributed to a fatal issue, and in nearly all cases injured the woman for no good purpose. He did not consider his method ideal, and believed that even now further improvements could be made.

#### *Ovarian Extract after Artificial Menopause.*

Dr. W. T. HAULTAIN read a paper on the value of ovarian extract after an artificial menopause. It had been his practice for the last five years to administer ovarian extract orally in 5-grain doses for six months in cases where both ovaries had to be removed at operation either with or without the uterus. The method of administration was to decrease the dosage gradually, the patient beginning with 5 grains three times a day for the first two months, twice a day for the third and fourth months, and once a day for the fifth and sixth months, but if the symptoms became severe at any time the dose was immediately increased. In order to discover if there was any advantage in this treatment Dr. Haultain sent out a questionnaire based on similar questions asked by J. W. BRIDE, when he was investigating "the further results of removal of the uterine appendages in hysterectomy." The questions asked were: (1) Was the general health improved? (2) Had the patients become stouter since the operation? (3) Had they become very depressed? (4) Had they had severe flushings, for how long did the flushings last, and were they still present? (5) Did they suffer from headache? (6) Were there any marked nervous symptoms following operation? In all 31 replies were received, and of these 31, 24 had taken ovarian extract for one month or more. In those who had taken ovarian extract the results compared very favourably with BRIDE's results in 185 cases, as it was noted that the extract seemed to have helped the patients with regard to adiposity, headaches, nervous symptoms, but chiefly in regard to flushings. As the treatment had been given principally to try and relieve the flushings the results were very gratifying. The immediate result was very little better than in BRIDE's cases, but at the end of twelve months only 33 per cent. of the cases continued to have any flushings, whereas in BRIDE's cases 64.6 to 75 per cent. suffered from flushings after twelve months. Among the hysterectomies only 20 per cent. had flushings after twelve months. About a year ago it was pointed out to Dr. Haultain that injections of ovarian extract might be more beneficial than the oral administration, and for the last year he has treated all his cases by the injection of 1 c.cm. of whole ovarian extract twice a week combined with the oral administration of 5 grains once nightly. He had treated in all 13 cases for a sufficient time to estimate the value of the method, and from a short summary of the cases he showed clearly that with further injections the flushings became very slight, and in many cases entirely disappeared. Several patients had been operated upon some months previously and had suffered severely from flushings; when injections were started the flushings in practically every one of such cases were much improved, and in a large number entirely ceased. Dr. Haultain therefore recommended this treatment for a period of three months at least, especially in younger women where both ovaries had had to be removed at operation.

## Reviews.

### THE FRENCH MEDICAL SERVICE IN THE WAR.

A FURTHER contribution to the history of the great war has been made by Franco in the publication in 1926 and 1927 of *Le Service de Santé pendant la Guerre 1914-1918*,<sup>1</sup> which is the work of Médecin Inspecteur Général A. Mignon. Realizing the magnitude of the task he has undertaken and the vast amount of research entailed, we offer the author our congratulations on the successful outcome of his labours. This history of the French medical service during the war comprises four volumes of 700, 664, 710, and 832 pages respectively, and in this comparatively small compass Inspector-General Mignon has contrived to present a record of every side of medical work during the campaign. His energies have centred chiefly on France, as is only natural, and very little mention is made of the French forces operating in other theatres of war. The author's plan has been to study the war year by year, treating each year from a different medical point of view, and wherever possible he has chosen to discuss events of which he had first-hand information. He has given us succinct accounts of the salient features of every department of the French medical service, combining history and criticism in a manner at once pleasing and instructive.

To be fully appreciated the volumes should be studied in sequence, though separately each has its own tale to tell. Volume i is a recital of trials and tribulations, of pre-war schemes and regulations put to the test of actual warfare, and of reconstruction. The author boldly criticizes the lack of supplies and the means of transport, which hampered the work of the medical service. He shows how the bitter experience of the early battles taught the need for modifications, for new ideas to meet new conditions, for a reorganization of the medical service, and how, during the period of stabilization, administrative difficulties beset their path—as indeed they did until well on in the war. Taking the Third Army as typical of the others, he describes events in Argonne, where disease, in the form of enteric fever, was the greatest enemy; he points out that failure on the part of those in command to realize the necessity for the complete antityphoid inoculation of the troops resulted, in this army alone, in 39,712 cases in seventeen months.

In volume ii we have a very interesting account, from the medical aspect, of the defence of Verdun, dealing in considerable detail with the preliminary attacks from February to June, 1916, and in broader outline with the final operations in 1916 and 1917. The historian speaks with authority concerning the early months, since to him was entrusted the task of preparing and organizing the medical service for the defence. It is with no uncertain pride that he reveals for the first time in print the part played by the medical service in withstanding the fierce onslaught of the enemy on Verdun. A preliminary survey of the medical formations in his charge showed a standard of efficiency as high in some as it was low in others. The task that lay before him was to bring order out of greatest chaos, to inspire enthusiasm and keenness where these had waned, to reorganize the medical formations round Verdun, and to prepare schemes for the care of sick and wounded and for their evacuation from the fortified area. He pays grateful tribute to the loyal assistance of his own staff, but deplores the lack of co-operation on the part of the General Staff and their desire to keep back essential information regarding the movement of troops—factors that will always seriously affect the conservation of man-power, the morale, and the mobility of an army in the field. From this volume the reader gains a vivid impression of the intensity of the struggle—of the almost superhuman efforts of the stretcher-bearers to collect the wounded from the battlefield in the dead of night, and of the difficulties of evacuation under almost constant shelling. It comes as no surprise to learn that

the toll of the French troops at Verdun was roughly 50,000 killed and 216,000 wounded, not counting sick and gassed.

Volume iii passes in review the medical service in action during the offensive operations of the Somme and the Aisne and in Flanders in 1916 and 1917, during the German offensive of March to July, 1918, and during the final advance to victory from August to November, 1918. The author has followed closely the development of the battles day by day as far as possible, taking first the front line medical service and following the progress of the wounded through clearing hospitals to the base. At the same time he has dealt extensively with medical preparations for the attacks, showing wherein lay success and where failure, and emphasizing the importance of co-operation, a point always overlooked in the early days of a war. He shows that it was only when disaster had overtaken the medical arrangements, made with insufficient knowledge of the plans of the General Staff, that the need for joint action was brought home to that service. How reminiscent this is of our own failures in France, Gallipoli, Mesopotamia, and East Africa! Thereafter the medical service was given a place in the councils of the staff, and at last assumed that autonomy which it felt was essential to its most efficient working. This was a wise provision and an acknowledgement that the medical service of a great nation in a world war, when it evacuates, in round numbers, 10,000,000 sick and wounded, does more than doctoring, and becomes a national trustee for conserving the man-power of an army, worthy of whole-hearted trust. The United States, we understand, followed this principle and other nations might well do likewise.

The final and largest volume recapitulates the results, lessons, and developments brought out in the previous volumes. The author has given a broad survey of the cause to which this evolution of the French medical service should be ascribed. We note with pleasure that he emphasizes strongly the importance of the penetration into the army medical service of civilian doctors, surgeons, and specialists; this factor is sometimes overlooked by a regular medical service, but it should never be forgotten for it means that a splendid reserve is always at hand ready and willing to give of its best. The author acknowledges the debt which the medical service owes to civilian aid, to its directors and those who guided its progress, to the various scientists and learned societies of France who unsparingly contributed their knowledge, and to the French Red Cross and other aid societies, who augmented its personnel. Taking each in turn he indicates the part they played throughout the campaign and their influence on the development of the medical service. Changes in regard to the utilization and distribution of personnel, medical and surgical, are discussed in the light of experience, together with improvements in the material and accommodation at their disposal. An entire section is devoted to the development and working of the army medical service from front to base. The progress made in the treatment of wounds, in the evacuation of casualties in the means of transport, in the prevention and cure of disease, in surgery, in hygiene, radiology, and the treatment of gassed cases, is given due significance.

Statistics of sick and wounded have been recorded for specific battles or from separate hospitals, and a short chapter deals with the world's losses in the war. Comparing the statistical records of the French Army with those produced by the United States Army for the period of its campaign, Inspector-General Mignon puts in a plea for the establishment of a separate statistical bureau at headquarters in the event of any future war, so that a true record of statistics might be kept daily, to afford accurate deductions for the benefit of the General Staff and to give a basis for lessons in the saving of men. It is a wish that might find echo in the British medical service.

It would be difficult, even if it were desirable, to compare this medical history with the British official *Medical History of the War*, eleven volumes of which have already been published. The abundant detail which the editor-in-chief, the late Major-General Sir William Macpherson, delighted to provide for his readers is necessarily lacking in a history confined to four volumes. There are one or

<sup>1</sup> *Le Service de Santé pendant la Guerre 1914-1918*. Par le Médecin Inspecteur Général A. Mignon. Paris: Masson et Cie. 1926 and 1927. (61 x 10: Tome I, pp. 700; 13 figures, 17 maps. Tome II, pp. 664; 9 figures, 18 maps. Tome III, pp. 710; 4 figures, 33 maps. Tome IV, pp. 832; 32 figures. 240 fr. the four volumes.)

two points, however, in the French history where, in our opinion, improvements might have been made. In the matter of illustrations we find 100 maps and 27 figures spread over the four volumes, and while these are clear and devoid of unnecessary detail, a more plentiful supply of actual photographs would have considerably increased the reader's interest. The only index comes at the close of the last volume, and takes the form of a table of synopsis, which seems hardly adequate to the importance of the work. A list of abbreviations used throughout the text and an explanation of the signs employed in the maps are given in the first volume only; a repetition in each volume would have been preferable. These are, however, small points compared with the achievement of the author, whose work brings credit to himself and his country, and will amply repay close study.

### PERNICIOUS ANAEMIA.

THE success of liver diet in the treatment of pernicious anaemia has stimulated fresh interest in the nature and etiology of this hitherto fatal disease, and Dr. CORNELL's monograph on *Pernicious Anaemia*<sup>2</sup> appears at a very opportune moment. Although the classical signs and symptoms of this disease are now pretty generally recognized, there is a large mass of information which has been collected bit by bit and been published in various journals and monographs all over the world, and which has hitherto only been available to those with the opportunity to hunt through an extensive literature. Dr. Cornell has brought this information together and has succeeded in turning what might easily have been merely a useful catalogue into a most pleasantly readable and extremely useful book.

In a volume that is full of odd and apparently unexplained observations which give much food for thought it is impossible to do more than note one or two of the points that will be of general interest; of these, the pages on the geographical distribution of the disease, the critical consideration of the diagnosis in those instances that have been reported in young children, the points in differential diagnosis from other diseases which may occasionally show a similar blood picture, and the interpretation of the newer methods of diagnosis by the measurement of the red cells will all find a general welcome. The historical survey of the early descriptions of the disease is eminently fair and well balanced, and throughout the book, although the author quietly indicates his own views, the various hypotheses that have been advanced by others all receive a just appreciation. Summing up the observations on the etiology of the disease Dr. Cornell concludes that it is a superstructure of blood system and nervous system changes superimposed on an unknown foundation, and that the widespread tissue involvement and the peculiar mass of biochemical changes support the view that the underlying fundamental change is a disturbance of metabolism.

The book begins with a chapter for non-medical readers that may perhaps be of more value in its country of origin than here; it ends with a bibliography which not only shows the enormous labour that has gone to its making, but also lays all students of the subject under a deep debt of gratitude to the author.

### CLINICAL PEDIATRICS.

CERTAIN volumes in the series of monographs on clinical pediatrics, under the general editorship of Dr. R. S. HAYNES,<sup>3</sup> have already been reviewed in these columns, and even the nine with which we are now concerned do not appear to have exhausted this subject. It may be said that as a whole the series is uneven, and while the price may not be high for volume xiv, for example, of over 400 pages, sixteen shillings is expensive for vols. i and xii, which contain only half this number of pages. Vol. i, on *Prenatal*

Care, by Dr. R. W. Lobenstine and Dr. H. C. Bailey, is specially disappointing—an unsatisfactory mixture of obstetrics and pediatrics discussed in a very superficial manner. Dr. C. G. Grulee and Dr. B. E. Bonar deal with *The Newborn* in two volumes, numbered ii and iii, of the series. The former is devoted to physiology and care, and the latter to diseases and abnormalities. This distinction is artificial, however, and leads to a great deal of overlapping. For example, the volume on physiology includes articles on asphyxia neonatorum and the haemorrhagic diseases of the newly born, while a discussion on the physiology of the urinary tract would be much more useful if it accompanied the account of disorders of this system instead of appearing in a separate volume. A section on breast-feeding is included, although vol. xii, by Dr. H. B. Wilcox, is devoted entirely to *Infant and Child Feeding*. This is one of the very short volumes already mentioned, and while in general it follows orthodox lines it cannot be considered satisfactory, in a series intended for the general practitioner, to deal mainly with artificial feeding, while breast-feeding is considered only in the two final chapters. Dr. Bronson Crothers writes on *Disorders of the Nervous System in Childhood* in vol. v, and this appears to be a very good contribution to the series. He regards the problem of exact classification as of academic interest only, and devotes himself to the more practical aspects. Can disorders of the nervous system be arrested? Is the lesion progressive? Can education be carried out if the process is no longer active? These are some of the questions he attempts to answer in a stimulating and provocative book. Dr. W. P. Lucas and Dr. A. H. Washburn consider *Diseases of the Blood and Blood-building Organs*, and the degree of overlapping present throughout the series is clearly shown here; the haemorrhagic diseases of the newly born are again discussed when the subject has been dealt with fully in vol. ii, with a brief summary in vol. i. It is unfortunate, too, that these accounts differ on certain points. Infective mononucleosis (glandular fever) is not mentioned except in a table. The account of purpura is good, and the discussion of such difficult subjects as splenic anaemia and Banti's disease is adequately presented. Dr. F. B. Talbot writes on *The Internal Secretory System and Metabolism* in a very satisfactory though small volume (xiii of the series). The normal metabolic processes and their pathological variations are well described, and deficiency diseases are discussed, with good illustrations, although one and a half pages seems a very small allowance for an account of the etiology and symptomatology of rickets. Here, again, overlapping is shown, for cretins and Mongols have already been described in detail in other volumes. *Infectious Diseases of Infancy and Childhood*, by Dr. H. L. K. Shaw, forms vol. xiv; it is a valuable exposition of modern views on these disorders; the question of prevention is kept well to the front, and each disease has the relevant American public health regulations set out at the end of the appropriate chapter. Rheumatic fever has been included, but only ten pages are allotted to this subject, which deserves fuller treatment. Dr. R. W. Bolling deals with *Surgery of Childhood* in vol. xv, excluding orthopaedics, which forms the subject of another volume already mentioned in these columns, and excluding also, apparently, diseases of the ear, nose, and throat. The omission of this latter "specialty" results in such troubles as the consideration of cervical adenitis or acute retropharyngeal abscess without any reference to tonsillectomy as an important measure in their eventual cure. Otherwise the volume gives a clear account of the special features of surgery as applied to the period of childhood.

### FOOD POISONING.

MISCONCEPTIONS still exist about the nature of food poisoning in circles well informed about other infectious diseases. For instance, it is common for illness to be ascribed to ptomaine poisoning in spite of the fact that every proper investigation of such illness has proved the cause to be *Salmonella* bacteria or their toxins. Dr. DAMON's book, *Food Infections and Food Intoxications*,<sup>4</sup> is a useful

<sup>2</sup> *Pernicious Anaemia*. By Beaumont S. Cornell, M.B. London: Cambridge University Press, 1927. (Med. 8vo, pp. xv + 311; 6 figures. 20s. net.)  
<sup>3</sup> *Clinical Pediatrics*. Supervising Editor: Royal Storrs Haynes, Ph.D., M.D. Vols. i, ii, iii, v, xi, xii, xiii, xiv, xv. New York and London: D. Appleton and Co. (Roy. 8vo, vol. i, pp. xiv + 211, 47 figures; vol. ii, pp. xvi + 258, 63 figures; vol. iii, pp. xviii + 429, 82 figures; vol. v, pp. xiv + 242, 64 figures; vol. xi, pp. xi + 233, 5 figures; 2 plates; vol. xii, pp. xiii + 202, illustrated; vol. xiii, pp. xvii + 178, 83 figures; vol. xiv, pp. xxiii + 415, 33 figures; vol. xv, pp. xxvi + 390, 202 figures. 16s. net each vol.)

<sup>4</sup> *Food Infections and Food Intoxications*. By S. R. Damon, A.M., Ph.D. London: Baillière, Tindall and Cox, 1928. (Roy. 8vo, pp. viii + 260; 13 figures, 18 plates. 16s. net.)

summary of present views on food poisoning, and it is to be hoped that it will be widely read. The essential difference between the old and the new point of view lies in this—that it was formerly believed that a poisonous chemical substance was produced during the natural decomposition of food, whereas the true view is that the toxic substances are produced by the growth of a well-defined group of pathogenic bacteria which cause disease in domestic animals, from which source human food becomes contaminated. This commonest of all types of food poisoning is well described by Dr. Damon, though it is to be regretted that he omits references to the Ministry of Health Reports and the Food Investigation Board Reports published since the year 1920.

The other, and much rarer form of food poisoning, botulism, is classified by the author amongst the food intoxications, and finds itself grouped with mushroom poisoning, grain intoxications, potato poisoning, and shell-fish poisoning. The only feature botulism shares with these other intoxications is that the symptoms are due to an organic chemical poison. Botulism differs from these poisonous foods in so many respects, notably in the fact that the germ injures food otherwise wholesome, that its separation from other bacterial diseases seems an artificial distinction. This second part of the book, headed "intoxications from food," is worth special mention because of the information it contains about such subjects as mushroom and shell-fish poisoning, which do not usually receive much attention in public health textbooks. The third part deals with the larger animal parasites transmitted by food and the method of diagnosis of helminth infections. The author does not make any claim to originality in the contents of this book, but he has done a useful service in collecting together in one volume information about the different agents which make food poisonous, derived from books on medicine, public health, bacteriology, chemistry, and biology.

#### OPHTHALMIC OPTICS.

Optics are a necessary part of the training and equipment of the ophthalmic surgeon. Compared with the fascination of clinical work, optics are dry as dust except to a very small minority of those who are mathematically minded, and who revel in equations that do not seem to equal. There has been much improvement in the teaching of optics of recent years. Teachers have clarified their own minds, and have been able to give clearer indications of simple laws. A recent book of American origin is a good exemplar of improved methods of teaching. *The Introductory Course in Ophthalmic Optics*,<sup>5</sup> by Dr. ALFRED COWAN, assistant professor of ophthalmology in the Graduate School of Medicine of the University of Pennsylvania, is an excellent piece of work. He has aimed at giving a working knowledge of ophthalmic optics to medical students and practitioners. He has tried to construct a system that can be followed by one having only an elementary knowledge of mathematics, but a system which is scientifically correct and not inconsistent with thoroughness. He has certainly succeeded in his endeavour. He proceeds from consideration of the elementary laws of light to reflection and refraction at plano surfaces, and then at spherical surfaces; thence to lenses, and the dioptric system of the eye. Myopia, hyperopia, and astigmatism are considered, then accommodation, and finally the clinical methods of ophthalmometry, ophthalmoscopy, and retinoscopy.

In each section the author not only gives the theory and mathematical demonstration of the subject under consideration, but there are experimental demonstrations which can be verified by the student, and which will convey to the least mathematically minded a conclusive proof of the proposition under examination. The rationale of the clinical instruments for the examination of the eye are stated with an enviable precision and directness. Retinoscopy is explained in eight hundred words and three diagrams, but the explanation is complete and accurate. It is a pleasure to come across a teacher of ophthalmology who tells his student that in retinoscopy it is the light reflex which is

the proper subject of observation, and that he should follow the movements of the light, and not of some delusive shadow.

The book is beautifully printed, and the diagrams are admirable. In many of these the ground plan of the problem is given in black ink and the answer to it in coloured inks—a method of printing that is without doubt expensive, but most impressive.

#### THE ALCOHOL PROBLEM.

Dr. H. M. VERNON, in his book on *The Alcohol Problem*,<sup>6</sup> gives a judicial survey of two important aspects of the question: one is the effect of legislation in this and other countries upon the consumption of alcoholic liquors, and the other is the experimental evidence at our disposal concerning the action of alcohol on the human organism.

In his consideration of prohibition in the United States the author is careful to point out that this was of gradual growth, and not a measure thrust on the country suddenly in a wave of war-time excitement. While the press in the United States, as in this country for the most part, is strongly anti-prohibitionist, medical opinion in the United States is strongly in favour of prohibition. Under the prohibition law any doctor who wishes to prescribe alcohol for his patients may do so after taking out a special permit, but it appears that only 22 per cent. of the medical practitioners in the United States hold permits at all. Although the law is flouted in the large industrial areas and the big cities, where in recent years there has been an increase in the number of deaths from alcoholism, in the agricultural districts and small towns, which contain the majority of the population, prohibition is accepted with complacency. Dr. Vernon is inclined to think that the real test of the efficacy, both in America and in Finland, of prohibition should come in twenty or thirty years' time, when the present generation of young people will have reached maturity and power. He next considers the system of partial prohibition in various countries, such as Canada, Australia, New Zealand, Sweden, and Norway, and comes to the conclusion that the principle of avoiding absolute compulsion is the correct one, especially if it is coupled with an unrestricted sale of comparatively innocuous beers containing 3 per cent. or less of alcohol. The methods for controlling the production and sale of alcoholic liquors in this country during the war are next considered, especially those relating to the hours of sale and high taxation, and a chapter follows on the English public house as it is, in which Dr. Vernon acknowledges his indebtedness to Mr. E. Selley's work (see *Journal*, September 17th, 1927, p. 496).

In his chapters on the physiological aspects of the problem Dr. Vernon, who has made so many valuable contributions to the subject, discusses the effect of moderate quantities of alcohol on efficiency, the extent to which food and dilution modify the effects of strong drink, and the influence of alcohol on length of life. He maintains, in opposition to Professor Raymond Pearl, that it will never be possible to obtain clear and conclusive evidence, though he is inclined to agree that the effects of moderate drinking on longevity are small. Although we find no discussion of the relation of liquor to poverty, crime, and prostitution, nor any reference to the place of alcohol in therapeutics, and might for these reasons regard the title as somewhat too wide for the contents, this book is of value as setting out the impartial views of a physiologist on a matter of outstanding importance.

#### NOTES ON BOOKS.

THE first edition of Dr. A. PINEY's *Recent Advances in Haematology* was reviewed in these columns on August 13th, 1927 (p. 269), and already a second edition<sup>7</sup> has appeared with considerable additions, such as a glossary of technical words likely to cause difficulty, among which is "pseudo-leucæmia," with the comment "a term best left to undergo atrophy from disuse." There is a new chapter on the spleen in various

<sup>5</sup> *The Introductory Course in Ophthalmic Optics*. By Alfred Cowan, M.D. Philadelphia: F. A. Davis Company. 1927. (Leiny 8vo, pp. 262; 121 figures. 35s. cloth.)

<sup>6</sup> *The Alcohol Problem*. By H. M. Vernon, M.A., M.D. With a preface by Viscount D'Abernon. London: Baillière, Tindall and Cox. 1928. (Demy 8vo, pp. xv + 252; 24 figures. 9s. net.)

<sup>7</sup> *Recent Advances in Haematology*. By A. Piney, M.D., Ch.B. Birm., M.R.C.P. Lond. Second edition. London: J. and A. Churchill. 1928. (Extra post 8vo, pp. x + 318; 4 plates, 18 figures. 12s. 6d.)

infectious, and additions have been made in the other chapters—for example, in connexion with the liver treatment of pernicious anaemia. The chapter headed "Haemorrhagic diatheses" includes Werlhof's disease (as he prefers to call purpura thrombopenica, inasmuch as the implication of any etiological hypothesis is thus avoided) and aplastic anaemia. Here will be found also an account of David's disease—a haemorrhagic disease so far observed only in women, without evidence of infection or constant thrombocytopenia, and regarded as possibly due to endocrine disturbance. In the preface Dr. Piney replies with some spirit to criticisms in reviews of the first edition, but considering the interesting character of the work as a whole he should perhaps regard these as compliments to be silently accepted.

Various clinical methods, routine procedures, and therapeutic measures have been collected together into a *Clinical Handbook for Residents, Nurses and Students*\* by Dr. Victor M. Coppleston, who edits the volume which members of the staff of the St. Vincent's Hospital, Sydney, have written. There are a large number of procedures, often handed down by tradition among the resident workers in a hospital, which are seldom adequately dealt with in books, and it is certainly an advantage for the young house-officer to know something of the ways in which enemata are given, for example, and of the general management of special cases, such as ophthalmic, ear, nose, and throat, and gynaecological patients. The chapters on sterilization, minor surgical procedures, poisoning, and anaesthetics are especially valuable, and it is evident that throughout the book all the methods described are in everyday use at the hospital to which the authors are attached.

\* *Clinical Handbook for Residents, Nurses and Students*. Edited by Victor M. Coppleston, M.B., Ch.M., F.R.C.S. Sydney, Australia: Cornstalk Publishing Co. 1928. (4½ x 7, pp. 153.)

## PREPARATIONS AND APPLIANCES.

### "Ambidex" Wrist Splint.

DR. REUBEN LEVINSON (Goodmayes) sends a description of a simple modification of the Carr splint for Colles's fracture which he has devised. He writes: At present a separate splint is required for the right and left hands. The ease with which one somehow always succeeds in unearthing the right-hand splint when the left is required, and vice versa, is too well known to need enlarging upon, and it consequently occurred to me that a splint which would be suitable for either

hand would be a very definite advantage to the busy medical practitioner and to medical officers of hospitals. In the Carr splint the hand-grip portion is fixed to the head of the splint, but in my modification the hand-grip is arranged on a hinge, which thus makes it possible to swing the hand-grip over from one side to the other for either right or left hand, as the case may be, the faces of the splint being shaped accordingly to take the thenar eminence. This new splint is produced by S. Maw Son and Sons, Limited, 7-12, Aldersgate Street, London, E.1, under the name of the "Ambidex" wrist splint.

## PAPWORTH VILLAGE SETTLEMENT.

### CLIFFORD ALLBUTT MEMORIAL COTTAGES.

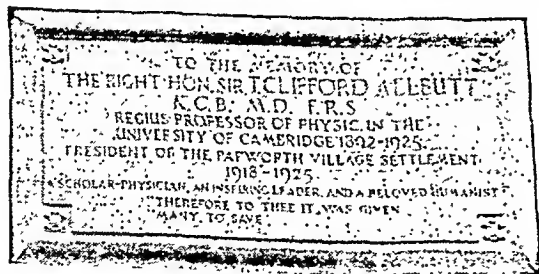

As a memorial to the late Sir Clifford Allbutt, who was president of the Papworth Village Settlement from 1918 to 1925, two cottages have been erected at the settlement from funds subscribed by members of the medical profession. Photographs of the cottages and of the inscribed stone which records the significance of the memorial are reproduced on this page.

The opening ceremony at the cottages was performed by the Prince of Wales on the occasion of a visit to Papworth last month, when he spent about three hours in making an informal but very complete tour of the settlement, under the guidance of the director, Dr. P. C. Varrier-Jones. At the opening of the Clifford Allbutt memorial cottages a brief address was given by Sir Humphry Rolleston, the present president of Papworth,

men pass out into hostels, where the unmarried remain, while the married are housed, with their wives and families, in cottages when these can be provided.

For women patients the present provision is inadequate; there is available accommodation for only five cases, and it is desired to create a similar system to that existing for men. A sum of £4,000 is needed, and up to the present £1,500 has been secured.

The Papworth Settlement is, apart from other considerations, notable for the development of many crafts and industries among its patients. Work is begun as soon as their condition permits, many of the workshops having been started to provide occupation for patients who already possessed a knowledge of some trade or other when they entered the settlement. Among the industries carried on

The Memorial Stone.

and Lady Allbutt was presented to His Royal Highness. The cottages are being occupied by tuberculous ex-service men who, after treatment in the Papworth sanatorium, desire to settle in the village with their wives and families, and work in the industries.

It is now twelve years since operations were commenced at Papworth with the erection of two shelters in a garden. The Prince, in the course of his visit, saw a community where 500 consumptive patients are being treated, while numerous industries have been built up on a sound footing in what is the largest village settlement in the world. The village clusters round Papworth Hall, the former mansion, which now contains the main wards for men and in the grounds of which are chalets to accommodate some 90 men patients. From the wards and the chalets the

Clifford Allbutt Memorial Cottages, Papworth.

are carpentry, leather work, printing, and upholstery, but there are many others. The working day is restricted to six hours, and conditions are carefully regulated to suit the physical state of the workers. To the provision of facilities for useful activity is attributed the cheerful atmosphere which observers have noted as characteristic of the patients at Papworth. Many of them are men who at the onset or with the progress of the disease had not expected to be able at any time to resume work.

It is interesting to note, moreover, that the financial results have been far from unsatisfactory, when the physical

status of the workers and the limitation of the hours of labour, among other things, are taken into consideration. In the industries carried on, under the management of the tuberculous patients themselves, there has been, during the past nine years, a turnover of about £220,000, and the loss has been the comparatively small amount of £2,000. As it is, therefore, the industries have been practically self-supporting. Apparently they have been hampered by lack of adequate capital resources, and it is believed that if this deficiency could be overcome there would be no loss whatsoever.

## MENTAL HYGIENE.

### THE PREVENTION OF NERVOUS BREAKDOWN.

A WELL-ATTENDED public meeting, arranged by the National Council of Mental Hygiene, was held in the Birmingham Council House on June 21st. A letter was read from the Minister of Health, Mr. Neville Chamberlain, expressing warmest sympathy with the objects of the council, and regret that duties in the House of Commons prevented his attendance at the meeting. The Lord Mayor (Alderman A. H. JAMES) presided, and, in opening the meeting, described mental disorder as one of the most serious problems affecting the country, either on its social or economic side. In 1926 the cost of maintenance, supervision, and treatment of patients amounted to £8,000,000. The net cost to the Birmingham local authority last year was £181,546 for the treatment and care of 2,655 patients, and this was equivalent to a rate of 8d. in the £.

Addressing the meeting on "The prevention of nervous breakdown," Sir MAURICE CRAIG said that physical health had long been the special care of municipalities, but, except for the care of the insane, the mental health of the people had been almost entirely neglected. The word "mental" was considered synonymous with "insane," but now ideas, such as that the prevention of disease far outstripped in value the treatment of disease which had become established, must be developed. In the matter of the insane they had contented themselves with housing those who reached an advance state of mental disorder—a state which, in many instances, need never have been reached had the early phases of the illness been recognized and proper treatment been available. There was no fundamental difference between physical and mental disease. For example, one person might react to stresses, of whatever kind, on the physical side, whereas another might react to similar stresses by some change in mind. The importance of having general and mental hospitals working in close co-operation, and of having a mental clinic in every general hospital, was becoming evident. Mental disorder was not a bolt from the blue, as so many thought; serious disturbance developed, as a rule, slowly, and it was in the early days that it was important to discover what was causing it, and to treat it, and prevent its further development. The minor mental disturbances were of importance, and should never be ignored. It should be remembered that mind had many attributes, and that emotion was one of the most valuable attributes of mind. Emotion must be understood, for if it was allowed to run riot it might end in bringing about mental ruin. Passion—extreme emotion—could devastate the mind for the time being, so that the person so affected might be incapable of reasoned action or judgement. But lesser disturbances required serious consideration. A child whose emotional reaction was unstable might be almost uneducable. Again, disturbed emotion might lead to false reasoning, and false reasoning might give rise to altered behaviour, or to some other failure of adaptation to environment.

### Importance of Early Treatment.

There were two important factors in early treatment: (1) the proper understanding of mind and its activities by laymen; and (2) the wider teaching regarding minor disturbances of the mind in medical schools and hospitals. Now that they were appreciating that mind and its working was an integral part of what was called health, so much the more necessary had it become to see that the study of mind was not divorced from the teaching of

general medicine. The emotional reaction of a patient might determine the ultimate success or failure of a surgical operation, and this was equally true of disease. It was being shown by increasing and overwhelming evidence that mental fatigue was in many instances a matter of even greater importance than physical fatigue among the workers in great industries. Monotonous movement might exhaust the mind in certain types of person to a far greater degree than it fatigued the muscles employed in performing it. Mental hygiene, again, should play a very important part in education, not merely with defective and "problem" children, but with the highly intelligent and brilliant also. Living as they did in times when scholarship was so important a factor in education, they should never forget that the strength of the human brain lay in its slow development, and that if the central nervous system of a growing child were over-stimulated infinite harm might be done from which the child might never recover.

In conclusion, Sir Maurice Craig said that the subject of mental hygiene was a very large one, touching all mental activities from the cradle to the grave. It brought a fresh interest to parents watching the development of their children, while the worker would understand better how to get the best value out of his work and how to avoid the too common minor, but crippling, disabilities. Even in the present state of knowledge, if this were used to the full the number of the insane could be greatly diminished. The task now was to put into action the knowledge already possessed, for it was far better to spend money on prevention than on building big institutions. The present methods were economically wasteful; viewed from the standpoint of medical science they were deplorable, and when measured in terms of human suffering it was difficult to find words strong enough to condemn them.

### Need for Education of the Public.

Dr. CRICHTON MILLER said it was an incontrovertible fact that in affairs of the mind, as in affairs of the body, prevention was the only royal route to eradicate ineffectiveness. It did not matter whether one was dealing with early tuberculosis, or a knocking in the engine of a motor car, or slight irritability on the part of a daughter-in-law, in each case the remedy must be applied early to be successful. From the point of view of good citizenship "mental hygiene" meant a great deal; the phrase was coined in America for something that had not hitherto been thought of. People had lived with the impression that mankind was more or less the same except when mad, and that madness was a special problem unlike any other. If insanity happened in the family circle the other members hung their heads for shame. The whole question of mental hygiene, and the idea of keeping the mind healthy instead of regarding the problem as one that presented itself only when the mind was diseased, had had very little attention, and the public must be educated. A nation's interest lay in keeping its minds healthy. The old phrase *Mens sana in corpore sano* had been misinterpreted to imply that if the body were kept healthy the mind would remain healthy. That never was true, nor was it intended to mean that the mind necessarily remained healthy. If the problem were faced in this country as it was being faced on the other side of the Atlantic, this would make for national efficiency in a very remarkable way. In mental hygiene nothing like the same progress had been made as with tuberculosis. It was not possible to impart such accurate, full, and adequate information as the specialists could about tuberculosis, but an indication could be given on how to prevent nervous and mental breakdown to a certain extent, and it was possible, with the co-operation of the public, but not without it, to do something useful in that direction.

Then in order to impress upon his audience the way in which this problem of mental hygiene affected good citizenship, Dr. Crichton Miller gave a number of telling instances, drawn from the daily life of ordinary people, showing how many difficulties of temperament and character were due to long-past troubles which might have been overcome if only the person concerned had been treated at the right time by somebody trained in the methods of psychotherapy.

## British Medical Journal.

SATURDAY, JUNE 30TH, 1928.

### THE NATIONAL HEALTH INSURANCE AMENDMENT ACT, 1928.

THE National Health Insurance Amendment Bill was read a third time and passed in the House of Lords on June 21st. In our parliamentary notes we have from time to time reported the speeches made in connexion with the various stages of the bill, and have indicated the more important changes that have been introduced during its passage through the House of Commons. We have commented on its provisions on two previous occasions (April 21st, p. 677, and May 12th, p. 811), and now that the bill has been passed in its final form it may be well to recall some of the main points to which attention has been directed in these columns. There are, as we have said, many things in the Act—such as the simplification effected in some of the insurance arrangements, and the establishment at last of a real insurance scheme for deposit contributors who, owing to ill health, are refused membership by approved societies—with which the medical profession is in hearty agreement; but there are others which have excited great misgiving, and which will need both vigilance and firmness on the part of the profession if their effect is not to be detrimental to its liberties, traditions, and interests. Some of these dangers were set out in the two articles to which reference is made, and they have not been removed by any effective amendment of the bill.

In the first place, the Act is one more example of the practice, severely condemned by the Lord Chief Justice and many others, of legislation by the indirect method which authorizes a Government department to make Regulations and prescribe conditions under which various actions may be taken. There are said to be in this comparatively short Act no fewer than sixty-six occasions on which such words as these are used giving the Minister of Health power to impose his will in a manner not specified. Parliament ought by this time to know its own mind in the matter of health insurance legislation, and to those who need it the protection afforded by Statute Law is better than that afforded by Regulations. Our second criticism is that the profession has not been quite fairly dealt with by those in charge of this measure. Before the bill was introduced the British Medical Association received more than one assurance from the Ministry of Health that there would be little or nothing in it which affected the medical profession. The fact has turned out to be that it contains provisions of the utmost importance, especially to those practising as consultants and specialists. In this way the best opportunities for making representations on these points were lost. Next, when it was discovered that the bill actually proposed to repeal Section 75 (5) of the Act of 1924—the only effective safeguard against the interference of approved societies with the medical profession in connexion with additional treatment benefits—it was asserted by the Ministry that the reason and justification for this repeal were that the only additional benefit to which the section could apply had been removed from the list of such benefits;

and it was left for us subsequently to discover that words had been introduced into other specified additional benefits placing them now in a category to which the section would have applied if it had been allowed to remain. Again, when after discussion with the Ministry an amendment had been agreed to ensuring that any scheme by which an approved society contributed towards treatment of its members at a clinic should at the same time make provision for this to be available from practitioners elsewhere than at the clinic, and it was pointed out that the particular amendment adopted by the Ministry offered these forms of treatment as alternatives so that clinic treatment by itself could still be adopted by a society, no attempt was made by those in charge of the bill to remedy this defect and carry out the arrangement which had been accepted. These are grounds for complaint, even though some of the points may yet be safeguarded by Regulations.

It is true that much of the dissatisfaction with the Act arises from what it omits to do as well as from what it does. Lord Gage, moving the second reading in the House of Lords on behalf of the Government, said: "Mr. Chamberlain would have liked the adoption of the Royal Commission's recommendation that the surpluses of approved societies should be partially pooled to enable specialists' services to be made a statutory benefit. The suggested pooling was the only method whereby the necessary funds could be obtained without recourse to the Exchequer. The approved societies have, however, so set their faces against this that Mr. Chamberlain has been prevented from making this necessary and desirable extension." In the House of Commons Sir Kingsley Wood had already said that "but for the opposition of the approved societies it would be perfectly possible to put into operation the scheme for specialist services without bringing any additional funds into the national insurance system at all." Thus the approved societies have been discovered, and unequivocally declared, to be a gigantic obstruction to the main advance, most urgently needed, which ought now to be made in the public health services of the nation. This cannot be forgotten, and should be proclaimed and emphasized at every suitable opportunity. Whatever the usefulness of the societies in some other directions, this remains true. At the same time the Ministry and the Government have shown themselves weak enough to tolerate this obstruction, instead of insisting, at the cost of a little time and courage, on clearing it out of the way. It is claimed that the methods of the new Act in this regard are an alternative, even though they are unsatisfactory and need an apology. In fact, they are not an alternative at all. To tinker with additional treatment benefits for a certain number of privileged insured persons—who, on the whole, need these less than those who do not get them—by permission of the more prosperous approved societies and by means of Regulations reflecting the differing views of successive Ministers, is in no sense a substitute for a publicly organized specialist service for all insured persons alike. When it is found, moreover, that under the proposed system an approved society or a combination of societies will be able to influence strongly, and may even be able to control, the provision, the equipment, the administration, and the staffing of clinics, institutions, or schemes for providing consultant and specialist advice and treatment, it is imperative for the medical profession to express its opinion of legislation which makes this possible, and to give no countenance to any such action. The Council of the British Medical Association at its last meeting

declared that "it is essential, if the medical profession is to take part in the provision of additional treatment benefits, that these, as is the case with statutory medical benefit, shall be administered in such a fashion that the services of the medical practitioners who elect to give advice and treatment in connexion therewith shall not be under the control of any approved society or societies," and that this position ought to receive statutory recognition. It has not received statutory recognition under the new Act. The word "control" in the Council's resolution is admittedly of uncertain connotation in some respects; but it must be remembered that control is often insidious, and may, in fact, be acquired by a minority. Freedom from the administration and control of approved societies, even though this were to be governed by Regulations made by a Minister, was won for general practitioners at an earlier stage. It is equally the duty of the medical profession to see that consultants and specialists are not faced with the alternative of either abandoning a legitimate sphere of practice or submitting to conditions which the experience of the profession in former times has proved to be intolerable.

Under the new Act the Ministry of Health has secured for itself many increased powers, which the present Minister may use wisely and others possibly not so wisely; but it has done this by weakening the position of the medical profession, and in some respects by enhancing that of approved societies. It should be made clear, in these circumstances, that consultants and specialists will only be willing to offer their services under conditions which safeguard their liberties and traditions and assure that they are in no sense the servants of the representatives of approved societies.

#### THE HEALTH OF THE COLONIES.

THE principal speaker at the twenty-first anniversary dinner of the Royal Society of Tropical Medicine and Hygiene on June 20th was the Secretary of State for Dominion Affairs and for the Colonies, Mr. Amery, who gave an interesting review of the position in the colonies, more especially in the tropical dependencies, from the point of view of public health. The Colonial Office, he said, was one which combined many functions, but none was of greater importance than the function of Ministry of Health to the tropics. There was a time when the diseases of the tropics were regarded as the inevitable result of the climate, and only within the last generation was it learned that these diseases were no more inevitable than diseases in temperate regions. The first British statesman to realize clearly the implications of tropical hygiene was Joseph Chamberlain. In his famous dispatch in 1898 Mr. Chamberlain informed the Colonial Governments that he had had under consideration the important question of reducing the mortality among white people resident in the tropical zone. After consultation with leading medical authorities he decided upon two main lines of action. One of these was the establishment of a school of tropical medicine in London (which was soon duplicated at Liverpool, thanks to the generosity of Sir Alfred Jones), where medical officers proceeding to the tropics could be given special instruction in the control and treatment of the diseases encountered there; the other was the encouragement of scientific research into the causes of tropical diseases. Mr. Amery remarked that his famous predecessor was more immediately and directly concerned with the white administrators and traders, but it had since come to be realized that the problems of health for whites

and natives in the Empire were one. The mosquito and tsetse fly were no respecters of races. Mr. Amery then gave some figures showing the expansion of the colonial medical services since Mr. Chamberlain's intervention. The number of medical officers on the Gold Coast had increased from 21 to 100; in Nigeria from 7 to 161; in Ceylon from 34 to 363; in Fiji from 8 to 68. The colonial medical services now had a strength of over 1,700 officers, and were growing every year; the salary and status of these officers had improved also. Just before the war the ordinary salary of medical officers in West Africa and in East Africa was from £400 to £500; it was now, in West Africa, from £660 to £860, and in East Africa from £600 to £900. Mr. Amery expressed the hope that before many years had passed it would be possible to create something in the nature of a single colonial medical service, thereby enabling the best brains in administration to be available to the colonies which most needed them, irrespective of what a particular colony could afford immediately to pay. He claimed confidently that the general level of medical work in the colonial empire had never stood as high as at present. The increased number of officers available enabled more attention to be paid to prevention and research, and thus the officers were not left, as before, continually struggling with the problem of overtaking disease after it had occurred. The Colonial Secretary also touched on the establishment of the hospitals at Singapore, at Accra on the Gold Coast, and at Mulago in Uganda, and then spoke of the various special campaigns and investigations conducted with the encouragement or under the auspices of the Colonial Office. Among these he mentioned the investigation on sleeping sickness begun by the League of Nations, also the very important work done on malaria. He quoted some striking figures to illustrate the great improvement in the health of the tropics. In West Africa in 1904 the death rate of European officers was 27.3 per 1,000, and in 1926 it had fallen to 8.6; in the same period the invaliding rate fell from 67.2 per 1,000 to 19.2. In East Africa the death rate between 1910 and 1926 fell from 14.9 to 5.6 per 1,000, and the invaliding rate from 24.5 to 4.4. It was not possible to give exact figures with regard to the native population, but there was no doubt about the steady improvement here also. The last medical report for Uganda furnished an instructive comparison. In 1920 a sum of £61,000 was spent on medical services in that country; in 1926 the amount was £128,000; the number of new cases among natives treated at the medical centre increased from 62,000 in 1920 to 380,000 six years later. Finally, Mr. Amery spoke of the co-ordinating and other work at headquarters. He said that when he first took charge at the Colonial Office he endeavoured to remedy certain deficiencies in this respect. Two years ago he appointed a chief medical officer at the Colonial Office, whose business it was to keep the importance of the subject before the various administrations. A medical and sanitary advisory committee, a colonial medical research committee, and a bureau of hygiene and tropical disease were all functioning. On the periphery were the Committee of Civil Research, which linked up the Colonial Office with all the other research activities of the Government; also the great schools of tropical medicine in London and Liverpool; and, not least important, the Royal Society of Tropical Medicine and Hygiene, whose health it gave him great pleasure to propose. Dr. Andrew Balfour, who replied, mentioned that the fund for a memorial to Sir Patrick Manson had now reached a total of £3,324. Lieut.-Colonel W. P. MacArthur proposed in happy terms the health of the guests, to which Sir Squire Sprigge responded, and the final toast was the health of the chairman—Professor J. W. W. Stephens, president of the society—which was proposed by Dr. Manson-Bahr.

## EXPERIMENTS ON ANIMALS.

IN last week's *Journal* (p. 1079) we reported the second Stephen Paget Memorial Lecture delivered by Sir Bernard Spilsbury, who spoke on "The work and responsibilities of the pathologist" at the annual meeting of the Research Defence Society. Some excellent illustrations were given by Sir Bernard Spilsbury of the achievements of pathology in the prevention and cure of disease by means of experiments on animals, not merely by immunization against particular infections, but in other ways also, and not merely in the human race, but also in sheep and cattle and domestic animals. It is important that clear and simple illustrations of this sort should from time to time be given to the public, even though their reiteration may seem wearisome to the well informed, for there is no relaxation in the campaign of prejudice and misrepresentation which is being conducted by the British Union for the Abolition of Vivisection, and even by more respectable bodies. An interesting example of a better method of discussion is to be found in the recent correspondence in the *Times* between Sir Bernard Spilsbury and Lord Dawson of Penn on the one hand, and Mr. Stephen Coleridge on the other, though even here it is unfortunate that one or two letters of an altogether different calibre of intelligence have been allowed to appear, and that Mr. Coleridge has been unable to suppress an unworthy but characteristic method of controversy by implying that Lord Dawson is not truthful when he gives a particular instance (necessarily anonymous) in which the use of a mouse has been of service in the case of a boy at one of our public schools. The correspondence began through the complaint of a general hospital that it had some difficulty in getting subscriptions owing to the agitation of certain persons against the holding of a Home Office licence for vivisection by the pathologist on its staff. The claim is that, as Lord Dawson says, "the advantages which accrue to mankind by the use of animals in the study, diagnosis, and treatment of disease can be determined only by those possessed of the necessary special knowledge," mainly scientific and medical workers; and that, so far as these advantages exist, those who are willing to profit by them should not be deprived of their opportunity by the exertions of those who have come to the conclusion that it is ethically wrong so to do. Mr. Stephen Coleridge is, of course, right when he claims that "to many people it is not a question of medicine, but a question of ethics and conduct." It is not open to the expert to deny the advantages; but it is open to them consistently to refuse to accept or use them if they believe them to be achieved by methods ethically wrong. Some such persons (we accept Mr. Coleridge's statement that he is one of them) do refuse treatment by inoculation, but we doubt whether they do, or can, refuse the benefits of much other knowledge gained by means of experiments on animals. But even putting the code of ethics of Mr. Coleridge and his associates at its highest, it is not open to them to impose this upon the medical profession or upon the far greater number of patients, whether in hospital or elsewhere, who, when faced with the quite simple alternatives offered to them for alleviation or cure, do not feel that there is any ethical difficulty whatever.

## INTERNATIONAL CONTROL OF THE TRAFFIC IN OPIUM.

At the recent meeting of the Council of the League of Nations a report from the Advisory Committee on Traffic in Opium and Other Dangerous Drugs was received, to the effect that it is expected that the Geneva Opium Convention of 1925 will come into force in the near future. The new convention is designed to strengthen the Hague Opium Convention of 1912; a notable feature is the provision made for the establishment of a permanent central board to

collect and collate information regarding the world supply of drugs, and to pronounce whether a State is in any given year exceeding the amounts to which it is legitimately entitled. Considerable delay has been experienced in securing the ratification of the convention, and it is only recently that satisfactory progress has been made. The position when the Advisory Committee's report was drawn up was that fifteen States in all had ratified, including four States members of the Council, two being permanent members, as required by the convention. The Netherlands and Rumania have since formally signified their adhesion, and when the Council met the Canadian ratification was reported to be imminent. Several other States are taking steps to conform to the movement. The committee was therefore able to state that there is every prospect of the convention being in operation before the end of the year. From accounts given to the committee, to which we made reference on May 26th (p. 907), it is obvious that energetic and highly organized action is needed if the traffic in dangerous drugs is to be kept within bounds. Great importance is attached by the committee to the collection of full, prompt, and accurate information: there has been some improvement in this respect, but certain producing countries, such as Bolivia, Greece, Peru, and Persia, are not yet giving the desired details, while some discrepancies have been noted in the figures received at Geneva. The Advisory Committee devoted considerable time to a discussion on the constitution of the proposed permanent central board to be set up under the 1925 convention, but in the result most of the details were left to be settled at a later session. A recommendation was received from the League Health Committee that a number of morphine compounds, known as esters of morphine, of which benzoyl-morphine is an example, should be brought under the convention, since they may be abused in the same way as morphine. The convention permits the addition of fresh products to the list of those subject to its control.

## FINE WORK AND EYESTRAIN.

LAST year a report was issued by the Medical Research Council on the effects of eyestrain on the output of linkers in the hosiery industry; in this work the detail to be discriminated is so fine that, however high the illumination provided may be, the eye must be kept quite near the object, with the result that some degree of continuous strain is imposed on the muscles of convergence and accommodation. The investigation clearly showed that benefit was to be gained from the use of spectacles, with which this strain was relieved and output increased. In a new report<sup>1</sup> published this week the investigation has been carried a stage further; each operative brought into the investigation has been examined by an ophthalmic surgeon, Mr. T. G. Clegg, and for each appropriate glasses have been provided, giving the necessary correction for any error of refraction and muscle balance, together with the additional correction for the relief of the excessive convergence and accommodation. Particulars of the glasses ordered are given, and these show that a considerable range of error of refraction was found. Part of the work was connected with weaving and part with mounting electric lamp filaments; both processes are very fine; both demand not only perfect illumination, but power also on the part of the operative to get close up to the work for prolonged periods. No work more likely to cause eyestrain could be chosen. So far as these tests have gone—and their only weakness is the relatively small number of operatives tested—there is strong evidence of the value of

<sup>1</sup> *On the Relief of Eyestrain among Persons performing very Fine Work.* By H. C. Weston and S. Adams. Medical Research Council, Industrial Fatigue Research Board. London: H.M. Stationery Office. 1928. Pp. 25. Price 1s. 3d. net.

the glasses. The relief and assistance thus afforded to the workers enable them substantially to increase their rate of output, the amount varying, in individual cases, from about 8 to 26 per cent. for drawing in (weaving), and from less than 1 per cent. in an exceptional case to nearly 20 per cent. for filament sorting and mounting (lamp making). These figures refer only to experienced workers, and there is evidence that a still greater increase may be expected in the case of learners. It is believed that with them the use of the glasses would shorten the period required to attain proficiency. Particulars are given of each set of experiments, and of the nature of the illumination provided, with graphs of the results. The report concludes that: "It is, therefore, obviously desirable, in the interests of worker and employer alike, that the sight of candidates for fine work should be tested and any defects properly corrected."

#### THE "DRINK-MORE-MILK" CAMPAIGN IN THE UNITED STATES.

THE Danish expert on nutrition, Dr. M. Hindhede, has recently returned from a voyage of discovery, or what would be more accurately described as a tour of critical inspection, in the United States. His impressions are recorded in the journal of the Danish Medical Association, *Ugeskrift for Læger*, for May 31st. The heading of his paper, "The American milk agitation," gives a clue to his own opinions of the efforts made there to induce children to drink more milk. To the casual observer this movement might seem to be inspired by undiluted philanthropy, but Dr. Hindhede has a wonderful scent for the sinister and the dramatic, and his suggestion that capitalism and the farming interest are behind this movement is not to be dismissed offhand. His criticisms fall into two categories: the first may be disposed of in a few words, for in telling such stories as that of the unnamed woman professor who was obliged to resign her appointment because she taught that milk is decidedly not good for any child after a certain age he is not supported by any serious documentation. Also, such vague statements as "I could tell a good deal more of the same kind" are unconvincing. More interesting, and perhaps to some people more convincing, are his criticisms of Professor E. V. McCollum's book *The Nutritional Value of Milk*. This work records experiments in an institute for negro children, some of whom were kept on the institute's original diet, while others were given this diet with the addition of milk. According to Dr. Hindhede, as much as 96 per cent. of this original diet was practically vitamin-free; 3 per cent. contained an uncertain amount of vitamins, and only 1 per cent. contained a more or less ample supply of them. Almost any combination of foods would give good results compared with those obtained with such an unsatisfactory diet; by reducing the vitamin-free proportion of a diet to 52 per cent., and making 42 per cent. of it rich in vitamins, the result, comparatively speaking, must be good, whether the addition of vitamin-rich substances be of milk or of potatoes *plus* other vegetables. Incidentally, Dr. Hindhede points out that, in Professor McCollum's experiment, together with the addition of milk to the original diet, other vitamin-rich foods were increased five times in relation to the calories. Indeed, the milk-fed children received 22 per cent. more calories than those on the original diet. This inequality was, it is true, made good at a later date, but the caloric value of the original diet was brought up to that of the milk diet by the addition of still more vitamin-free foods such as white bread and sugar. Dr. Hindhede suggests that Professor McCollum would have obtained the same results as with the milk diet had he dispensed with milk, reduced the bread ration of the original diet, given wholemeal bread instead of white, and greatly increased the quantity of potatoes and other vegetables. A litre of fresh milk a day for each child is liable to upset the budget of a working-

class family, and the inclusion of much milk in a dietary containing normal quantities of proteins is calculated to be injurious. Referring to Professor McCollum's work and the recent investigations of Dr. Corry Mann (criticized by him in an earlier communication<sup>1</sup>), Dr. Hindhede concludes: "Thus, I cannot see that any proof exists in favour of the teaching that it should in general be profitable to give children a large supplement of milk. The American experiments are just as unconvincing as the English experiment already discussed."

#### CENTENARY OF KING'S COLLEGE, LONDON.

ONE hundred years ago, on June 21st, 1828, at a meeting convened by the Duke of Wellington and the Archbishop of Canterbury, the movement which led to the institution of King's College, London, now an integral part of the University of London, was initiated. Soon afterwards the Crown granted the site adjoining Somerset House in the Strand which the college still occupies, and the new addition to the educational facilities of London came into existence. The illustrious sponsors of the project were moved, perhaps, more by the fear that the newly opened University College, an institution of Radical and Non-conformist colour, might be the means of luring the youth of the "Church and State" party in the rising middle classes from their allegiance than by any passion for the democratization of higher education. King's College was originally, therefore, a very definite rival to the sister institution in Gower Street. The two colleges are still rivals, but in a healthier fashion, and the old party and religious divisions were soon forgotten in a disinterested enthusiasm for learning. In the development of education in the metropolis and in the advancement of science the college has played a large part; it has changed in form and constitution with the establishment of the University of London, the erection of the theological department into a separate school of the University, and the organization of the advanced medical school and the hospital as an independent body. These developments were referred to at a commemorative dinner given at the college on June 21st, when the principal, Dr. W. R. Halliday, in replying to the toast of "The College," spoke of the number of great institutions which it had nursed to maturity and then launched to success. Dr. Halliday added that the time would come when it would be necessary to appeal for funds to carry on the work of the college and to extend its capacity for service. Though flourishing in numbers, he said, it was practically unendowed. Capital expenditure for building which could not be postponed must necessarily be met, and so long as the work of the college was wholly dependent on a fluctuating income from fees, it could not carry on its work as it would like that work to be done. He wanted to convince all members of the college of the overwhelming importance of the present opportunity. Upon their success in turning it to account would depend the future of the college during the years which lay ahead. Great institutions dared not stand still; but—it was best to face the facts—without a very large sum of money they could not go forward. In the course of the proceedings reference was made to the loss sustained by the college through the death of Lord Hambleden, described as "the greatest of its modern benefactors," who was chairman of the delegacy of the college. Lord Hambleden, it will be recalled, was also keenly interested in the welfare of the voluntary hospitals in London, notably in connexion with King's College Hospital, in the administration of which he played a leading part for many years. He participated actively in the business of the British Hospitals Association, and was for a time honorary treasurer of that body.

<sup>1</sup> *Ugeskrift for Læger*, 1928, p. 92.

## MUSEUM OF THE ROYAL COLLEGE OF SURGEONS.

THE Conservator, in his report for the year ending June, 1926, notifies that the additions to the museum of the Royal College of Surgeons of England will be on view in Room I from July 5th (the date of election of new members to the council) until July 28th. One of the largest donations during the year was the Strangeways collection, consisting of several hundreds of specimens of chronic arthritis. These have been handed over to the College by the trustees of the collection, and, with Dr. Strangeways's manuscripts, have been entrusted to Mr. Lawford Knaggs for investigation and revision. The more important research work carried out at the museum includes investigations on nerve suture and nerve regeneration by Sir Charles Ballance, on the pathological changes in cases of colitis by the Conservator, on the evolution of the lymphatic system by Mr. R. H. Burne, and on the anthropology of certain native African races by Mr. L. S. B. Leaky. In the pathological department the curator, Mr. Cecil Beadles, reports the addition of 150 new specimens, and refers more especially to specimens of papillary tuberculosis of the Fallopian tube, carcinoma of the male urethra, old gunshot injury of the brain, necrosis with ossification of the muscles of the thigh following suppuration, the bones from a case of craniocleidodysostosis, malignant endothelioma of the tibia, adamantinoma of the infundibulum, torsion of the gall-bladder, a large lymphadenomatous tumour of the thymus removed by operation, and a fine series of specimens of Recklinghausen's disease showing extensive affection of the cranial, spinal, and sympathetic nerves and the rare condition of involvement of the periosteum (of the tibia) in the hyperplastic process. In a number of specimens (the gift of Dr. William Hunter) from cases of pernicious anaemia are shown the glossitic, gastritic, and enteritic changes which he has described as the starting point of that disease. Two interesting preparations of the afferent vessels of the lymphatic circulation in the cod illustrate Mr. Burne's researches above referred to. Numerous additions have been made in the department of osteology, the most important being an exact cast of the Taungs skull, the gift of Professor Raymond Dart, whose description of the original appeared in *Nature* (February 7th, 1925). In connexion with the compilation of the new catalogue of osteology, Miss Tildesley contributes some interesting notes on skulls from the Andaman Islands, the Dutch East Indies, the Philippines, New Guinea, and the Torres Straits. The Odontological Department, which was closed for structural repairs last year, is now open for the use of students; many additions have been made to the collection, including a series of casts, about 100 in number, presented by Sir James Berry, illustrating the operative measures adopted in the treatment of cleft palate.

## THE ROYAL SOCIETY CONVERSAZIONE.

At the summer conversazione held last week at Burlington House the scientific exhibits in many instances had already been staged at the previous evening function held on May 17th, and were described in our issue of May 26th (p. 912). Of historical interest were the manuscript of Sir Isaac Newton's *Principia* and his marginal notes in the first edition. Drs. Adrian and Bronk gave a demonstration of the impulses travelling up sensory nerve fibres with a rather ingenious mechanism. As each impulse is accompanied by a minute electrical discharge lasting about a five-hundredth part of a second, they amplified the electric changes by thermionic valve, so that when a skin-nerve preparation of the frog set on appropriate electrodes was touched by a camel-hair brush the magnification was sufficient to operate a wireless loud-speaker. Sensory messages can thus be transformed into sound waves, and the same

method can be used to demonstrate the electrical changes accompanying muscular activity. The Marino Biological Association of the United Kingdom gave an interesting demonstration of the modes of respiration in living marine animals, showing how in the varying conditions of existence the animals develop mechanisms for continually bringing fresh sea water in contact with their bodies, a blood circulation with specialized respiratory areas, and respiratory pigments (compounds of iron, copper, vanadium) in the blood to increase its oxygen content. Dr. Pearson and Mr. Hopwood showed specimens of the teeth of fossil animals found in the rocks in China—the so-called "dragon's teeth" of the Chinese medicine men, who use them as charms to cure all manner of diseases. Perhaps the most interesting exhibit of all, and certainly one that attracted much attention, was the demonstration by Messrs. Colour Photographs, Ltd., of their new process of colour photography, which will soon be put on the market. The method would seem to be simple and straightforward enough to be carried out by the average amateur photographer, and when it is realized not only that natural colour transparencies can be taken by the ordinary camera without colour filters or multiple exposures, but that they can be printed on paper in true colours with very little trouble and reproduced as often as is desired, it is probable that the process will become very popular. In order to obtain the negatives a three-ply film pack is inserted into the dark slide in the usual way. The pack is composed of three celluloid films, each about one three-thousandth of an inch in thickness, which are coated with gelatin emulsions of selective colour sensitiveness, and they are arranged in such an order that the front film, which is blue-sensitive, has its uncoated surface towards the lens; next comes the yellow-sensitive film, with its coated side in contact with that of the first; and then behind comes the red-sensitive film. For all practical purposes it may be said that the sensitive surfaces lie on one plane. The photograph of the object is taken in the usual way. It was stated that most of the exposures, certainly for the portraits, were made with half-watt lighting and took about three seconds each. Thus the plate is very speedy in comparison with autochromes, and it is possible that snapshots could be taken outdoor with good lighting. The triple negative is developed, and the three parts appear like ordinary negatives without colour. Each constituent film is inserted in the usual printing frame with a special sensitized transparent cellulose tissue, which is thin but very tough, and they are printed out by direct exposure to light, so that one obtains a yellow, a red, and a blue print from the respective negative films. The printed tissue is simply washed and fixed and hung up to dry. In order to obtain the finished result the red print is wetted and "squeegeed" on to a sheet of paper, a cementing fluid is rubbed over it, the yellow print is superimposed and easily registered, more cementing fluid is applied, and lastly the blue print is put on top, and all of a sudden the true colours emerge and the composite picture is finished. Prints can also be made from panchromatic plates which have been exposed through three coloured filters, and probably this method would give sharper detail.

## OXFORD OPHTHALMOLOGICAL CONGRESS.

THE full programme of the eighteenth annual meeting of the Oxford Ophthalmological Congress has now been issued; preliminary details were given in our issue of March 17th (p. 460). Accommodation has again been offered at Keble College, and members will assemble there informally on the evening of Wednesday, July 4th, at dinner. The meetings will be held in the Department of Human Anatomy at the University Museum, and concurrently there will be an exhibition of ophthalmological instruments and apparatus. On July 5th the congress will be opened

by Mr. Philip H. Adams, the Master, and Professor Leonard Hill will introduce a symposium on "The ultra-violet ray," followed by Mr. W. S. Duke-Elder and others. Subsequently Mr. G. R. de Beer will give an address on "Recent experimental work on the development of the eye and associated structures." The afternoon will be devoted to a series of demonstrations on various aspects of ophthalmology—devices for tests and operative treatment, pathological specimens, drawings illustrating diseases, and the like—and in the evening the annual dinner of the congress will be held in the Hall of Keble College. Professor Arthur Thomson will deliver the Doyne Memorial Lecture at 11 a.m. on July 6th, his subject being "Observations on the eyes of birds." Before this a series of short papers will be given, Lieut.-Colonel Henry Smith dealing with "The nutrition of the lens and vitreous—a speculation," Mr. Burdon-Cooper with "Spectroscopy of the crystalline lens," and Mr. George Young with "Double sclerectomy as now performed by the author." During the last hour of the morning session a paper on "Sympathetic ophthalmia" will be read by Mr. T. Harrison Butler. Arrangements have been made for the members of the congress to visit the Morris motor works in the afternoon. The closing session, on the morning of Saturday, July 7th, will be given to reports of clinical cases, contributed by seven ophthalmologists from various centres. Copies of the programme and other information may be obtained from the honorary secretary, Mr. Bernard Cridland, Salisbury House, Chapel Ash, Wolverhampton.

THE Sheffield Medical School will celebrate the centenary of its foundation on July 11th. Among the ceremonies will be a congregation at the University, when the honorary degree of D.Sc. will be conferred upon Dr. H. H. Dale, Professor Arthur J. Hall, Sir Frederick Gowland Hopkins, Sir Thomas Lewis, and Professor Otto Warburg of Berlin.

AMONG the recently elected foreign members of the Royal Society are Dr. Albert Brachet, professor of anatomy and embryology in the University of Brussels; Emeritus Professor Richard Friedrich Johannes Pfeiffer of the University of Breslau, celebrated for his discovery of the bacillus bearing his name, and for his general researches in bacteriology, immunology, and protozoology; and Dr. Richard Willstätter of Munich, well known for his researches in organic chemistry. Lord Melehurst (formerly Sir Alfred Mond) and Sir William S. McCormick, chairman of the Advisory Council on Scientific and Industrial Research and of the University Grants Committee, have been elected Fellows of the Society.

## THE POST-ENCEPHALITIC PATIENT.

REPORT BY DR. ALLAN PARSONS.

THAT mysterious and distressing malady encephalitis lethargica continues to elude the attacks of the research worker; and the clinician is in no better case, since diagnosis is hampered by the protean manifestations of a disease which was stated by Sir Farquhar Buzzard to be "almost defiant as to treatment and prognosis." It is not surprising, therefore, that Dr. Allan C. Parsons, a medical officer of the Ministry of Health, has found his path beset with difficulties in reporting an inquiry undertaken by him into the after-histories of persons attacked by encephalitis lethargica.<sup>1</sup> Dr. Parsons was largely responsible for a comprehensive report on the epidemiology and clinical features of the disease, published by the Ministry five or six years ago, and discussed in the *British Medical Journal* of October 7th, 1922 (p. 654). His former efforts are admirably supplemented by the document now before us, which has been issued by the Ministry this week.

<sup>1</sup> Ministry of Health Reports on Public Health and Medical Subjects, No. 43, 1923. H.M. Stationery Office. Price 4s. 6d.

The first part of Dr. Parsons's report contains an analysis of data concerning some 3,500 patients, about one-fifth of the total number of cases notified from January, 1919, to December, 1926. The analysis shows that in every 100 cases investigated three years after the primary illness 25 patients, on the average, will have survived without serious consequences, 35 will have died, while 40 will have become more or less disabled in mind and body, or both. It is with the ultimate fate of the forty that the rest of the report is mainly concerned, in the hope of riveting attention on the serious consequences of the disease and the necessity for special consideration.

### *Defective Notification of Encephalitis Lethargica.*

The first difficulty upon which Dr. Parsons lays stress is defective notification. For this many reasons can be assigned. There is the comparative novelty of a condition which was first described by von Economo of Vienna in 1917. In the following year in this country Dr. Wilfred Harris and Professor A. J. Hall simultaneously directed the attention of the medical profession to series of cases, "presenting somewhat remarkable features," which had been observed by them in London and Sheffield respectively. The manifestations of a disease which has only been described so recently, and the incidence of which, in terms of population, is not great, are still unfamiliar to many practitioners. The onset is often insidious and the early symptoms slight. Epidemicity hardly exists away from large centres of population, and positive bacteriological tests are not obtainable. Then, again, many patients consult a doctor for the first time when they are already suffering from late effects of the disease, and many of the missed cases, when ultimately recognized, are not formally notified. The Health Department of the London County Council recently discovered 269 children suffering from late effects of encephalitis lethargica who had never been notified. Dr. Parsons estimates that for every 100 cases notified 50 to 75 cases are not officially reported.

The causes of imperfect notification help also to explain local differences in mortality. Taking the year 1924, which was noteworthy for a very marked epidemic form of the disease, though by far the least fatal of the nine years under review, Dr. Parsons explains the low mortality figures in Sheffield and Glasgow, as compared with Newcastle and Lancashire, by differences in the extent to which mild cases of the disease were recognized. Intensive study in the former towns meant not only the bringing to light of a larger number of mild cases, but also the excluding of some other fatal conditions from the encephalitis lethargica list.

### *After-Effects in Adults.*

There is the further difficulty that a patient after recovering quickly from a mild attack of the disease, and remaining well for months or sometimes years, may develop sequelae which in the end may even prove fatal. In proportion to the comparatively small number of persons attacked there is probably no infectious or contagious disease in this country which produces so much consequent ill health and disablement as encephalitis lethargica. And, though the results of the disease in children are deplorable, and have attracted much attention, Dr. Parsons is concerned to show that the effects on a wage earner or on his wife are no less deplorable. The case of the dribbling "old man" of 15, hunched up in his chair, impassive and slowly dying of Parkinsonism, is set beside that of the intelligent workman who loses job after job and eventually drifts into a Poor Law institution or an asylum, and that of a housewife who becomes lethargic and melancholy, incapable of attending to the needs of her husband, her children, or herself. The pathos of these pictures drawn by Dr. Parsons in his report is relieved to some extent by the account of the female Parkinsonian patient at West Park Mental Hospital who, taking part in some athletic sports, came in first in the 100 yards race! As Dr. Parsons says, *Vires acquirit cundo*. The variability of this symptom or syndrome, which occurs in perhaps 30 to 40 per cent. of those suffering from sequelae, is shown by the record of the young woman whose case seemed hopeless on account of severe Parkinsonism who eventually earned her living as a dancer.

*Classification of Mental Sequelae.*

The late mental manifestations of encephalitis lethargica have been described under many headings. Dr. Mapother broadly classifies them into (a) morbid restlessness, (b) demoralization, (c) "mental anergia." Restlessness he thinks characteristic of cases in children under 8, demoralization in juveniles between 8 and 20, while mental anergia is most common in those over 20 years of age. Dr. Parsons seems to prefer a broader grouping into the depressed and the excitable, and quotes a writer who puts post-encephalitis patients into two groups—"the irritable group of patients who get into trouble with the police or try to throw themselves under a train, and the apathetic group, content to stay at home and look at the fire."

About 27 per cent. of those who suffer from sequelae show symptoms of mental impairment. Sleep disorders are troublesome, and especially the insomnia which turns night into day—the "inverted sleep rhythm" so common in children. A curious occasional sequel is abnormal fatness. A fortunately rare sequel in bedridden sufferers is bedsores. In summing up the differences between the effects of encephalitis lethargica on adults and children, Dr. Parsons says that children show more signs of restlessness and excitement than do adults, whose reactions are more passive and negative. Conduct perversion is common in the former, confusion and the usual symptoms of insanity in the older patient. Some physicians state that children are, generally speaking, more prone to mental, and less to physical, sequelae than are adults.

*After-Care and Control.*

In dealing with the after-care and control of disabled patients Dr. Parsons points out that there is little difficulty in securing treatment for those in the acute stage of the disease. General hospitals are quite willing to admit such patients, the risk of infection to other patients or the nursing staff being very slight. The risk, however, appears to be not completely absent, and instances of infection have been noted in Lancashire and at Portsmouth.

When the acute stage passes off a time arrives when the general or the fever hospital finds the patient no longer welcome, and his bed is required for more urgent cases. Yet the patient is not fit to resume his normal occupation, and in many cases is unfit to resume home life. It appears from the report that a variety of institutions and bodies exist to whose care such a patient can be entrusted; and yet the position, according to Dr. Parsons, is not satisfactory. The Guardianship Society at Brighton may board the sufferer out in a carefully chosen family, or assist in obtaining training and employment suitable to his capacity, and by visiting take a friendly interest in his moral and material welfare. The local education authority may allocate for further care and education children whose training has been impeded by mental or moral deterioration, or may transfer a child to a "special school." The Metropolitan Asylums Board has an "encephalitis lethargica unit" at its Northern Hospital at Winchmore Hill, and other institutions such as Darent Training College. If the mental condition of the patient is such that he can be certified, he will come under the care of the Board of Control; while the Poor Law authorities are largely concerned with poor persons who suffer from the after-effects of encephalitis lethargica.

But, failing all these agencies, a number of post-encephalitis patients are bound to come under the purview of the Home Office, owing to their appearance in a magistrate's court. Dr. Parsons summarizes the various methods—including whipping—which are applicable to juvenile offenders, and shows how frequently offenders may drift into reformatories or Borstal institutions. It is interesting to learn that in some cases the discipline of such institutions has a markedly good effect on the young post-encephalitic patient. The fact remains, however, that, notwithstanding the long list of institutions to which patients may be sent for after-care and control, Dr. Parsons finds that considerable administrative difficulties exist in dealing satisfactorily with certain individual cases or even groups of cases.

*Disposal of Difficult Cases.*

The question of disposal is governed by two considerations: (a) the age of the patient; (b) the nature and extent of his incapacity, especially as regards mental changes. At the school-going age the attention and discipline of the normal children are distracted by association with a post-encephalitic child. On the other hand, the conduct changes in such a child impose severe strain upon teachers in schools for backward children. In many cases, therefore, committal to a reformatory or an industrial school becomes necessary; and during the year 1924 it was found that in about 8,000 children and young persons under detention there were at least 26 with a history pointing to encephalitis lethargica. By the end of the following year 87 such children had been admitted to these schools.

In adolescents the apathic post-encephalitic presents a difficult case. When his period of detention and reformatory training is over, his return home is liable to lead to relapse. If he is transferred to a Poor Law institution, the guardians, unless they adopt him, have no power to retain him unless he wishes to be retained; and the power of adoption only applies so long as the patient is under 18 years of age.

In the majority of older patients the problem, though tragic, is generally domestic. From the medical side the degree of mental disablement is the determining factor in the disposal of the patient; and unfortunately certification is rarely possible except after a lengthy and miserable period of progressive mental or physical deterioration.

Dr. Parsons concludes that the great difficulty lies with patients who, by reason of profound mental disturbance or in consequence of serious moral delinquencies, require special supervision and control in the interests both of themselves and of society. It is especially with the case of the juvenile in this class that the difficulty arises; and it is necessary to consider not only the probable effect of any particular kind of institution upon the patient, but also the patient's effect upon the institution—its normal inmates and staff.

In addition to these troublesome sufferers, consideration has also to be given to the problem of those who have become incapable of fending for themselves, and, while not attracting the same public attention, cause much domestic anxiety and expense. They are often helpless and apathetic creatures, erratic in their behaviour, and absorbing much of the time and energy of their relatives. Such patients tend to wander in and out of a variety of different institutions, without any benefit to themselves or permanent relief to their friends' anxieties.

*Special Institutions: Merits and Defects.*

It is evident that Dr. Parsons leans to a solution of the problem of the treatment of the post-encephalitic by the establishment of special institutions. In his view such institutions would not only lead to improvement in the condition of some of the patients and provide suitable supervision for the rest, they would also serve as valuable clinics for the study of the after-effects of the disease. He admits, however, the existence of an opinion that the association of all classes of cases in such an institution might be too close, and that individual patients might suffer in consequence. And the experience at Winchmore Hill has already suggested that one of the functions of a special institution should be the preliminary sorting of patients. It is noted also that those in charge of the French encephalitis unit—La Colonie de Perray-Vaucluse—receiving boys from 6 to 16 years of age, are doubtful about the value of establishing special institutions for such patients, and consider that they would be better treated under arrangements already existing for backward or mentally impaired children.

It will be gathered from what has been said that Dr. Parsons's inquiry forms a valuable addition to the reports on public health and medical subjects issued by the Ministry of Health; it sets forth ably and in an interesting manner the difficulties connected with the treatment and disposal of the post-encephalitic patient; and it suggests for discussion a possible solution of these difficulties.

## Scotland.

### Scottish Hospital for Crippled Children.

A PUBLIC meeting, under the chairmanship of the Lord Lieutenant, was held at Peebles on June 19th, in connexion with the scheme for building a hospital for cripple children to supply the needs of the south-east area of Scotland, which was outlined in the *British Medical Journal* of May 19th (p. 873). Sir David Wallace, F.R.C.S., who described the proposals, said that one criticism that had been heard was that one or other of the present hospitals might be used for this scheme, but the answer to that was that a central special hospital was essential to co-ordinate the whole scheme. In this there would be a competent surgeon to deal with all the cases, and in it all the essential work would be done. In the cottage hospitals of outlying districts the patients would be treated after the necessary stay in the central hospital. The surgeon of the central hospital would also visit outlying districts and give advice. They were asking from the charitable public a sum of £75,000 to carry the scheme into effect, and, after this, maintenance of the patients would be provided by the local authorities and from Government grants. The scheme would also be of great service in helping to reduce the waiting list in connexion with large institutions, such as the Royal Infirmary of Edinburgh. A committee was appointed to secure support for the hospital in Peeblesshire. Donations amounting to approximately £27,000 have already been received for the hospital.

### New Home for Blinded Sailors and Soldiers in Glasgow.

The Lord Provost of Glasgow, Sir David Mason, on June 11th, opened a branch of the Scottish National Institution for Blinded Sailors and Soldiers at 2, Queen's Crescent, near St. George's Cross, Glasgow. The institution has since the war been accommodated at Newington House, Edinburgh, where the headquarters still remain, but it has been found desirable to open a workshop in the West of Scotland, and the new quarters will provide accommodation for nineteen men. The Rev. Dr. Thomas Burns, chairman of the institution, who presided, said that since the institution was inaugurated in 1915 over £166,000 had been contributed to its funds. The occupations in which men had been trained included boat repairing, basket, brush, and mat making, poultry farming, and pig breeding. The men, after conclusion of their training, had been settled at various places throughout the country and had been assisted with a settlement allowance of £150 in each case. In all 140 men had been trained and most had done well afterwards; some, however, had found great difficulty in obtaining orders and were handicapped by lack of accommodation in their homes for the work. The committee had in operation workshops in Edinburgh and Glasgow, where the men not only could carry on their occupations to advantage, but had the benefit of companionship and daily intercourse. In the workshops at Newington House, Edinburgh, thirty trained men were now employed, and it was hoped that similar success would attend the Glasgow branch. Lord Provost Mason, in declaring the branch open, remarked that the hardship imposed by the necessity of travelling would be minimized. The work at Newington House, Edinburgh, had proved a great blessing, and was deserving of whole-hearted public support. He hoped that the citizens of Glasgow would give their cordial support in the way of orders to the men employed in the local workshops.

### Larbert Colony for Mental Defectives.

A meeting was held at Larbert House on June 16th, under the auspices of the Royal Scottish National Institution, Larbert, with the object of enlisting public support for the industrial colony scheme for the care of mental defectives. Sir Alexander Gracie (Glasgow), chairman of directors, presided, and said that in purchasing the large estate at Larbert House the directors had undertaken a great responsibility, but they hoped to be able soon to secure the necessary amount of money for the erection of

the buildings. The scheme had been largely supported in Edinburgh, but Glasgow had done relatively less for it than any other place. Dr. R. D. Clarkson, medical superintendent of the institution, also addressed the gathering, and explained that it was very necessary from the Scottish national point of view that the scheme should be completed as early as possible. The visitors afterwards inspected the mansion house, which is at present being used for thirty-six cases whose relatives can afford to pay. A number of the children performed musical games and gave demonstrations of physical exercises. This institution is the only national voluntary organization in Scotland for mental defectives; it has been in existence for the past sixty-eight years, providing a home and training for over 500 defectives under 21 years of age for a considerable time past. There is, however, at present no proper provision for many defectives over the age of 21 years, and it is to remedy this that the directors of the institution have purchased Larbert House and estate with the object of building up an industrial colony for such defectives. A sum of £50,000 is still required before the scheme can be completed. A commencement is to be made with the erection of some of the buildings at an early date.

### Hospital Accommodation in Edinburgh.

Considerable interest has been recently taken in the future of Craigleith Hospital, Edinburgh; it was used during the war as a military hospital, and afterwards by the Ministry of Pensions, and reverted to its original proprietors, the Edinburgh Parish Council, on May 28th last. The matter was considered by the Parish Council on June 18th. It was pointed out that the hospital and children's home could be made available for occupation in a very short time and that the two present Poor Law hospitals at Craigleith and Seafield were much overcrowded. It was finally decided to remit the whole question to a committee, with full powers to arrange for the reconditioning and occupation of the children's home, which is adjacent to the hospital, and for the reconditioning and use, immediate and future, of the main buildings. It was intimated that approximately £11,000 was available, representing the sum which had been received by the council from the Scottish Command in respect of structural reinstatement of the buildings, and which had been held in suspense since 1921.

### Noise in Relation to Health.

The Public Health Committee of the Edinburgh Town Council recently considered the question of noises during the night in relation to their effect on health. The matter was brought up on a letter received from the Edinburgh and Leith Division of the British Medical Association, recommending that the local authority should seek greater power to suppress unnecessary noise in the night, by having it declared that any noise between 11 p.m. and 6 a.m. which is capable of being prevented or mitigated, and which is dangerous or injurious to health, should be a nuisance within the meaning of the Public Health Acts. By this means it was considered that the public health authority would obtain powers to deal with such disturbing factors as discordant noises produced by motors, noise and vibration caused by heavy vehicular traffic through residential areas, uncontrolled barking of dogs, and the noisy dispersal of evening parties. It was reported to the committee that there was no evidence to show that ordinary noises of the street had a prejudicial effect upon the organs of hearing, although interference with natural sleep and detrimental effects on the nervous system should be considered as the more important effects of noise and excessive vibration. The report of the Division was minuted by the Public Health Committee for further action.

### Proposed Crematorium for Edinburgh.

The Edinburgh Cremation Society, which has been in existence for a number of years, has now obtained an option from the town council to purchase the house and grounds of Easter Warriston as a site for the erection of a crematorium. Arrangements are being made to form a public company with a view to raising the capital required.

The grounds are very attractive, and the house is a handsome stone building in good condition. Sir Robert Lorimer, R.S.A., has prepared plans for adaptation of the house with chapel, columbarium, retiring rooms, incinerating chambers, etc. The site occupies two acres and lies immediately to the east of Warriston Cemetery.

#### Chiropodists' Conference.

The Scottish Branch of the Incorporated Society of Chiropodists held its summer conference in Edinburgh on June 16th. The morning session of the conference was held at the Edinburgh Foot Clinic in Newington Road, where Mr. C. W. Cathcart, F.R.C.S., welcomed the delegates. He remarked that they were trying to get a register as a definite body, and said that even if they were disappointed for a time he would advise them to hold on and continue trying, and he had no doubt that in the future a definite register of chiropodists would be formed. He gave some interesting personal reminiscences of Lord Lister, under whom he had been a student, and described in detail various of Lister's operation methods. Dr. Cranston Low, physician to the skin department, Edinburgh Royal Infirmary, gave a lecture on some skin diseases affecting the foot, illustrated by wax casts, and at the evening session of the conference Miss Gertrude Herzfeld, surgeon to the Royal Hospital for Sick Children, gave an address on some problems in the diagnosis of foot conditions.

## England and Wales.

#### The Order of St. John and the British Red Cross Society.

STEADY progress in most of its activities is recorded in the eighth report on the work of the Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society. The report covers the period from April 1st to December 31st, the joint council having decided to close its financial year on the latter date instead of on March 31st as formerly; future reports will deal with the work of the calendar year. The number of cases helped by the department of auxiliary hospitals for officers now totals 17,789, most being ex-officers suffering from tuberculosis. Grants for bedside occupational work were made to nine hospitals, six being institutions under the Ministry of Pensions, and the value of these grants, as reflected in the outlook of the patients concerned, has been considerable. It is proposed to change the name of the fund making this provision to the "Ward industries fund." Between 900 and 1,000 men benefited from these grants during the period under review, and teaching and training were provided in twelve handicrafts. The emergency help scheme continues to do an exceedingly useful work in assisting sick and disabled ex-service men and their dependants who are unable to obtain relief from any other source. Over 30,000 new cases were dealt with in 1927. While this shows an increase on the previous year's total, the amount expended in grants was considerably less, and it is expected that the need for such relief will gradually decrease. The funds available are the residue of resources raised during the war, and they are being heavily depleted year by year. It is anticipated, however, that it will be possible to maintain the work, perhaps in an amended form, for some years. Many of the recipients of relief, the report again notes with satisfaction, have made voluntary refunds of amounts advanced. Over £11,500 was so repaid in 1927. Reference is made to the work of the Home Service Ambulance Committee, whose activities in this period, notably in the development of a first-aid service on the roads, were reviewed in the *Journal* of April 7th (p. 603). The mobile x-ray service has been increasingly employed, and although the unit is primarily intended for work near London, it has during the past year been sent as far as Cumberland. It is recorded with regret by the Tuberculosis Committee that a Leeds organization which had for over six years employed an average of 100 tuberculous men—largely ex-service pensioners—has gone into voluntary liquidation. There has again been a considerable shrinkage in some of the joint council's sources of

income, but exact comparison with the previous accounts is not possible, owing to the change in the accounting period and the fact that some classes of income are seasonal in their recurrence.

#### The Winsley Sanatorium.

The number of patients received in 1927 at the Winsley Sanatorium for Consumption, near Bath, was 354, this being above the totals for the two preceding years, but considerably below the number of admissions in the years 1922-24. In the later years, it is interesting to note, the average time spent in the sanatorium by patients treated to a conclusion has grown appreciably. In his report the senior resident medical officer, Dr. J. D. Macfie, discussing the value of graduated labour as practised at Winsley, regrets the tendency in certain quarters, notably among the younger medical superintendents and tuberculosis officers, to decry this. Dr. Macfie holds that the psychological factor is of the greatest importance in the treatment of pulmonary tuberculosis and, if finance permitted, he would like to see the grade system further developed at Winsley on the lines of the Papworth Colony. During the year there was a large increase in artificial pneumothorax cases; this procedure was attempted in thirty cases, in three after a spontaneous pneumothorax had taken place. There were three failures, and in four cases there was only a partial collapse, while in the remainder a good collapse was obtained. Sanoerysin is now being employed at the sanatorium, and a trial is being made with zomine, a preparation invented by Professor Charles Richet of Paris, regarding which Dr. Macfie states that he has not had enough cases to offer any final opinion, but that so far he is satisfied with the results. Tuberculin has been used occasionally; the only patient it seemed to suit was a pulmonary case complicated with tuberculosis of the kidney.

#### Reconstruction of the Middlesex Hospital.

The foundation stone of the west wing—the first part of the reconstruction scheme—of the new Middlesex Hospital building was laid on June 26th by the Duke of York. Prince Arthur of Connaught, the chairman, stated that the entire cost of the reconstruction would be £1,001,670. Since the launching of the scheme three years ago they had received £405,500, so in the course of the next five years, the period needed to finish the work, they had to obtain the sum of £596,170, and £137,700 was required by the close of the present financial year. The governors had set themselves to build a new hospital, a fully equipped outpatient department, and special departments. They would have to endeavour to provide a block for paying patients, as it was certain that in the near future no hospital would be considered up to date unless its service was so extended. In his speech after the ceremony the Duke of York, who was accompanied by the Duchess, recalled that for more than 170 years the Middlesex Hospital had ministered to the needs of many thousands of sufferers. Three years ago the governors were faced with a grave problem; serious defects in the fabric of the building were found, and the board was called upon to make a momentous decision. They now saw the first result of these careful deliberations in the laying of the foundation stone of the new hospital, of which that wing was only the first section. There was ample evidence that the courageous policy of the board was endorsed and approved by the public, who had already contributed very largely to the rebuilding of the hospital. The contributions of the anonymous friend who gave £200,000 for a new nurses' home, and of Mr. S. A. Courtauld, who has provided and partially endowed the new biochemical institute, referred to in our last issue (p. 1083), the Duke described as "magnificent." Continuing, he said there was every justification for the view that the public was becoming more keenly aware of the value of good health, both to the individual and to the community. Those who took part in the rebuilding of the hospital would be sharing in this great national work. He trusted that the new Middlesex Hospital might prosper in the noble task that lay before it. The Duke and Duchess afterwards visited the medical school, the Bland-Sutton Institute, and the Courtauld Institute of Biochemistry.

## Ireland.

### The Local Authorities Bill.

THE Local Authorities (Officers and Employees) Bill was introduced into the Dáil recently by Mr. De Valera, its object being to amend the Local Authorities (Officers and Employees) Act of 1926 in one particular. That Act provided that appointments under local authorities should be made on the nomination of a central board set up by the Government, the Local Appointments Board, only one nomination being made in each case. Mr. De Valera proposed that, instead of naming one person to be appointed, the Board should submit a panel of names from which the local authority should choose one; his argument was that the local authority should not be deprived of all power of choice in the selection of its officers. In opposing the bill Mr. W. Cosgrave, President of the Executive Council, said that the Act had been introduced for one main purpose—to secure in the appointment the best qualified person. Under the bill now before the House local authorities were to be invited to ask for a panel of not less than three, which would mean that canvassing and local influence would be resurrected. The purpose of sending down more than one name could only be to invite the local authorities to appoint someone other than the best qualified candidate. He further stated that the standard of applicants for the various posts had been good. Mr. E. Blythe, Minister for Finance, agreed that an inquiry into the working of the Act might be extremely useful. One of the results of the present system was that there had been great numbers of candidates coming forward, which showed that they had confidence in the methods by which they would be appointed. He saw no reason why officials should be chosen by a particular local authority, just as he saw no reason why civil servants should be chosen by a Minister, because officials were no more the servants of the council or local authority than civil servants were the servants of the Minister. Dr. T. Hennessy said that before the passing of the Act it often happened that a candidate—a medical candidate—passed his final examination one day, had his degree conferred, and then went down the day afterwards, and was elected to a position. Professional experience had mattered little so long as he had enough influential friends on the local board. Dr. Hennessy added that no defeated medical candidate had yet invited any body charged with the defence of professional interests to investigate the facts of an appointment on the ground that he had been unfairly rejected. It is expected that the bill will be defeated.

### School Medical Services.

At a conference of national school teachers held recently in Carlow, Dr. Robert Condy, medical officer of health, stated, in connexion with the medical inspection of school children, that it was the right of every child that his school life be passed with the greatest possible freedom from physical defects. If every child entering school received a thorough physical and mental examination, and was then dealt with according to his particular needs, from the infant up to the highest standard, the result would, in almost all cases, be a first-class health certificate when leaving school. Education without health was useless. The health of the growing child in nearly all cases determined the health of the adult. Dr. Condy suggested that no scheme for the treatment of school children could be complete unless consideration were given to those children under school age who were known to be defective, and the condition remedied without waiting until the child became of school age. The location, structure, and management of school premises and playgrounds was of much importance. A healthy, clean, sanitary environment, the betterment of home conditions, and the education of the parents and children in the prevention of disease were most essential objects. A well-trained school nurse was a link between school physician and teacher. The teacher needed the advice of the school nurse, and together they formed a combination which was bound to have a far-reaching effect on the health of the children.

## Correspondence.

### GASTRIC AND DUODENAL OPERATIONS.

Sir,—In to-day's issue of the *British Medical Journal* (June 23rd, p. 1055) Mr. Strong Heaney expresses his "belief" that my practice in regard to the surgical treatment of duodenal ulcer is an approach to that of the advocates of gastrectomy. I wonder why!

I do not perform gastrectomy for duodenal ulcer. I have not harboured one thought, uttered one word, written one line in its favour. I think it needlessly severe. The published experiences of those who perform it leave me quite unconvinced by their advocacy, and deeply confirmed in my contentment with simpler, safer, yet equally effective methods of treatment.—I am, etc.,

Leeds, June 23rd.

BERKELEY MOYNIHAN.

### MIDWIFERY MORTALITY.

Sir,—I would like to submit the following observations for the consideration of your readers. This increased mortality, if it is real—I have no statistical information on the matter—is due to the shortsightedness and stupidity of a body of medical men, who advised the Government of the day, when the Midwives Bill was introduced, that it was desirable to establish a licensed body of midwives, a trained body, to take the place of the untrained and ignorant women who acted in the capacity of nurses, but who did nothing—did not attempt to do anything—except wait by the bedside of the labouring woman: the responsibility for any examination, opinion, or interference, was laid upon the doctor.

In those days the doctors attended a large number of confinements (100 to 200 per annum) for relatively small fees—£1 1s.; in some districts 10s. These confinements constituted the backbone of a general practice. They were the criterion upon which its value was determined: the reputation for efficiency of the medical practitioner was popularly assessed by his skill in conducting midwifery cases; the loss of a maternity case, especially from puerperal fever, was the most serious thing that could happen to him. The very large experience he acquired, together with the advice and assistance he received from his elder brethren, very soon rendered him highly efficient. His income from his midwifery practice was from a sixth to a third of his total receipts.

All this has changed—partly owing to the Insurance Act, mostly to the establishment of a body of midwives who are licensed to attend cases, who are quite good as far as they go, but who are totally unfit to take the responsibility thrown upon them. Their existence has taken away from the medical practitioner a large mass of experience and a large slice of his income. He is now only asked to see the 10 per cent. of abnormal cases, while at the same time he is deprived of the experience which alone can enable him to distinguish the normal from the abnormal. If he is a wise man he will not attend midwifery cases at all if he cannot make £100 out of 100 simple and difficult cases; it is better for his reputation not to attend any. He cannot ask ten guineas for the difficult 10 per cent. of the cases. But still more serious is the fact that the reduction in the number of his cases has resulted, or must result, in rendering him inefficient—he has no longer the experience which alone can make him efficient; this is what the original advisers of the Government of that day failed to see. It did not matter for ten or fifteen years—there were plenty of efficient doctors then; that is not the case now, or it will not be soon. Very few medical men now have an experience of 1,000 cases, which, in my opinion, is necessary to make a man efficient in any part of his work.

In more ways than one the authorities appear to be losing sight of this fundamental fact. There is a tendency to create, for various purposes, bodies of whole-time doctors whose services are not available to the general public. From an administrative point of view this is probably the easiest and the best method, but it must have the evil effect of rendering less efficient the practitioners who are available to the public.

This is too serious a matter to be ignored. It was ignored when the Midwives Bill was passed, with the present or coming result that the public will have at their command a body of practitioners who cannot get the experience they must have to render them efficient, and a body of midwives whose professional training cannot render them capable of bearing the responsibility thrown upon them.—I am, etc.,

London, W.I, June 8th.

DAVID ROXBURGH.

#### PUERPERAL SEPSIS.

SIR,—I read with pleasure three articles on puerperal sepsis in your issue of June 8th. The address by Dr. James Young of Edinburgh interested me most, chiefly because of certain conclusions he arrived at.

In the first place, Dr. Young says there is evidence that trauma is the most important cause of the death rate from sepsis. I have long held this view. During the past twenty-six years I have, in general practice, attended slightly over four thousand confinements, and years ago I noticed how important a factor trauma was in puerperal sepsis. I do not recollect having a case of puerperal sepsis without it. Many times I have removed an adherent placenta by introducing the hand into the uterus, and have performed this operation in surroundings far from ideal—a dirty room, with a patient who had rarely enjoyed the luxury of a bath, lying on an unclean bed—and never with a bad result. Such cases always caused me much less anxiety than those in which trauma existed.

In the second place, Dr. Young concludes that there is need of an improved machinery for maternity practice based on a midwife-doctor combination. Such a combination is, undoubtedly, all-important. For several years I have insisted on better-class patients going to a nursing home to be confined, and the poorer classes I have refused to attend unless with a certified midwife co-operating. Since following this custom I have not had a single case of puerperal sepsis.

I am convinced that most cases of puerperal sepsis are due to trauma following the improper use of forceps. The doctor is busy, the patient impatient, and instruments are applied hurriedly and too early. With a competent midwife present this does not happen. She soothes the patient and her relatives till the time is ripe for the physician's appearance, and very often such cases end naturally, whereas if the doctor is working alone, or with the aid of one whose only qualification lies in the fact that she is "the mother of a dozen," forceps are applied early, with the usual lacerations and accompanying perils.—I am, etc.,

Dundee, June 18th.

HENRY BUIST, M.B., Ch.B.Ed.

#### ANAESTHETICS AND DIABETES.

SIR,—In the *British Medical Journal* of June 16th (p. 1017) Dr. George J. Laughey, in discussing operations upon diabetic patients, writes: "Chloroform is countermanded as an anaesthetic, but ether appears to be quite safe." This view, in regard to the safety of ether, is probably optimistic, especially if one also considers the ultimate results.

Thus Dr. O. Leyton, in the recent edition of *Treatment of Diabetes Mellitus*, writes: "In my experience the general anaesthetics—chloroform, ether, and nitrous oxide—have caused comparatively mild diabetes to develop into a serious condition." Dr. Leyton emphasizes the point that the effects may not be apparent at once, and cites a case in which the carbohydrate tolerance three months after operation (in which ether was used as an anaesthetic) showed a marked reduction. Hadfield, in *Practical Anaesthetics*, writes: "Chloroform is undoubtedly the most likely to cause this disaster [that is, coma], but ether is not very much better." Campbell and Macleod, in their monograph on *Insulin*, state that, "Ether should be used sparingly, if at all; chloroform never."

In these cases where an infection is present the deleterious effect of the anaesthetic is often obscured by the beneficial effect on carbohydrate tolerance that results from removal or drainage of the septic focus. It is generally agreed that chloroform should never be used, and most people are

also of the opinion that ether should not be employed unless it is essential for the operation. With the advance in the technique of local and spinal anaesthesia such circumstances should rarely occur. Gas and oxygen is considered to be preferable to ether although not free from objections.—I am, etc.,

London, N.W., June 25th.

S. LEVY SIMPSON.

#### IMMUNITY FOLLOWING HERPES.

SIR,—In regard to the recent correspondence on this subject—by Dr. James Taylor (May 26th, p. 920), Dr. H. W. Gell (June 16th, p. 1054), and Dr. H. E. Nourso (June 23rd, p. 1089)—it must be admitted that recurrence of genuine herpes zoster is occasionally seen, but I think that cases of typical "recurrent herpes" of the buttock or elsewhere should not be admitted as evidence against the teaching that true herpes zoster ordinarily confers immunity unless, indeed, it can be shown that the cause of recurrent herpes is the same as that of true herpes zoster. Amongst cases of "recurrent herpes" which have been described as cases of recurrent true herpes zoster I would include that of W. Richter,<sup>1</sup> partly owing to the actual illustration of the eruption that accompanies the description. The illustration shows a vesicular eruption in the lower left part of the abdomen of a woman, aged 46 years, and a similar eruption recurred during fourteen years in that situation whenever menstruation was much delayed on the day when the period should have commenced. Quite a number of the cases of "recurrent menstrual herpes" have been of gluteal distribution. The earliest reported case of recurrent gluteal herpes, according to Adamson, was that described by Bertholle in 1876. It was in a man aged 48, and may be compared to that in a man aged 32 years recently described by Dr. M. Obermayer as one of recurrent true herpes zoster. I have referred to many cases of "recurrent herpes" of the buttock or thigh in a recent paper.—I am, etc.,

London, W.I, June 23rd.

F. PARKES WEBER.

#### GLAUCOMA AND THE CAPILLARY CIRCULATION.

SIR,—It interests me much that Dr. Maitland Ramsay regards the state of the kidney in glomerulo-nephritis as analogous with the state of the eye in glaucoma, for, working on the renal state in eclampsia, I have looked at glaucoma as an example of a similar pathological process. Not that these two states, in their genesis, are comparable, but in their end-results. The increase of intraocular pressure causes blindness by interfering with the nutrition of the essential cells of the retina (by affecting the retinal capillary blood flow): in the pregnant woman, the rise of pressure on and within the kidney, by obstructing the blood flow through the kidney, causes degeneration and necrotic changes of renal tissue cells. I have maintained for some years that the visceral state in eclampsia is an example of ischaemia: the condition of the retina in glaucoma seems another example of this very common condition—witness the present discussion in your columns on "ischaemic contracture."

Dr. Ramsay believes that both these conditions—that is, glaucoma and glomerulo-nephritis—are due to a toxin. According to him the toxin causes a dilatation of the capillaries and an increased permeability of the capillary walls. I do not think this view can be maintained. In the case of the kidney, eclampsia occurs so often in the best type of pregnant woman, the healthiest and strongest, that the imputation of a toxin is unreasonable. In the case of glaucoma, although a toxin or an increase of waste products in the blood may always be present and be the predisposing cause, it does not seem to explain the condition in the way supposed. If the toxin acts primarily on the capillaries, causing their dilatation, etc., then if the supplying arterioles remain patent and the veins are not obstructed, however permeable the intraocular capillaries become, a continued blood flow—not a stagnation—through the eye must occur. The intraocular capillary blood flow must be continued because of the (up to now normal) pressure within the eye, which

<sup>1</sup> *Deut. med. Woch.*, 1925, li, p. 1279.

<sup>2</sup> *Medical Press*, 1928, clxxvi, p. 500.

"supports" the capillaries, and tends to prevent an undue dilatation. There must be some factor other than a simple dilatation of the capillaries: that factor seems to be an increase of pressure within the eye, and that increase of pressure the result of a chemical change.

"It is not the push of a capillary pressure," says Leonard Hill (p. 919), "but the penetrability of the endothelial membranes and the pull of the tissue cells, which is of first importance"—in the genesis of glaucoma. Duke-Elder (p. 1000) agrees. "Changes in the vitreous," says the latter, "are probably the most important factor," causing the increase in penetrability. We have only to assume that the osmotic pressure of the vitreous rises (for which, perhaps, there is reason) to see that an increase in volume of the vitreous and a rise in intraocular pressure would occur. The lens must thus be thrust forward, which would result in the exit of the aqueous into the canal of Schlemm being obstructed. The result must be an increase of pressure on the retinal capillaries, an obstruction to the blood flow, and an impairment in function of the retinal cells. Thus, in the case of the eye, if a toxin be present it would seem to act by affecting the vitreous, raising its osmotic pressure; in the case of the kidney of a pregnant woman about to become eclamptic no such toxin is necessary to explain the renal state.

It is clear that the flow of blood through the capillaries is of paramount importance for the health of the tissue cells, and it is at least reasonable to believe that the tissue cells, in respect of their varying activity, determine and control the blood flow through the related capillaries—doing so always except when pressure conditions arise interfering with the mechanism. Man consists of a mass of tissue cells, for which the blood and the capillaries exist: the tissue cells, not the endothelial cells of capillaries, are the master cells of the body. The pressure of the tissue cells upon their related capillaries must, as Leonard Hill has consistently taught, always be approximately the same as the pressure of the blood within those capillaries. The capillaries are such thin-walled structures that if the pressure outside them, caused by the activity of the tissue cells—for example, in gland and muscle—becomes greater than the intracapillary blood pressure—as, for instance, during systole of the heart—the capillaries become obliterated, the contained blood being compressed into the veins. If the pressure of the tissue cells upon the capillaries becomes much less than the pressure of the blood within the capillaries—if the arterioles do not constrict—an extreme dilatation and even a rupture of the capillaries with exudation of blood must occur. This happens in "shock." It is stated that in shock the dilatation of the capillaries is the primary change. In my view, the primary change is in the tissue cells. The Rouget cells, found on capillaries, imputed to act as dilators, possibly are sensory, not motor, in function. There must, at least, be some mechanism correlating the state of the capillary blood pressure with the state of the supplying arteriole—that is, with the aortic blood pressure.

The pressure within any capillary bed, necessarily depending (in the normal) on the activity of the tissue in question, and upon other internal and external conditions, must be constantly changing, and in different organs or body parts, at the same time, great differences of capillary pressure must exist. The pressure on the pulmonary capillaries, and thus the pressure within the pulmonary capillaries, at the top of Mount Everest is obviously greatly less than when at the base of that mountain. The pressure on the glomerular capillaries in the state of diuresis is obviously much greater than the pressure on those capillaries during a state of renal quiescence. So also must the pressure within the hepatic capillaries vary.

The arterioles of the several capillary beds react to the changing demands and to the physical conditions to which the body is exposed. At the top of Mount Everest the pulmonary arterioles must be constricted, obstructing the blood flow through the lungs, explaining the fearful fatigue experienced by individuals attempting the final stage of the climb. Otherwise, the pulmonary capillaries would burst. During diuresis, the renal arterioles dilate, allowing an excess of pressure to play upon the glomerular

capillaries, thus causing the blood to flow on rapidly into the tubular capillaries and away—without which urine could not be formed; the rise of pressure in Bowman's capsules supporting the glomerular expansion with a pressure equal to or almost equal to the blood pressure within the glomerular capillaries—the kidney becoming swollen and tense. It is plain the arterioles do not present the only peripheral resistance to the flow of blood; the great fall of pressure seems to occur at the outlet of the arteriole, where it expands into the capillary bed, but this fall only occurs during resting states. During activity of a part the capillary pressure within that part is considerable; but the pressure of the tissue cells now is raised, so that in the normal the integrity of the important part of the vascular mechanism—the part which matters—is conserved.—I am, etc.,

Rugby, June 9th.

R. H. PARAMORE, F.R.C.S.Eng.

#### WAR EMERGENCY FUND.

SIR,—In their all too generous tribute to the Honorary Treasurer and Honorary Secretary of the above Fund (*British Medical Journal*, June 16th, p. 1045), Sir Thomas Barlow and Sir Charles Ballance omitted to mention that the Fund owed its origin to the foresight of Dr. Samuel West, at that time President of the Royal Medical Benevolent Fund. He recognized that Territorial medical officers—at the time mobilized for the annual training, and many unable to return home to make arrangements for a long absence—must suffer financially. It was thus that the Fund came to be administered by the officials of the Royal Medical Benevolent Fund. Backed by the immediate response of the profession to the appeal for funds, Dr. West, through his personal influence, obtained a grant of £10,000 from the Prince of Wales's Fund. By his death the committee lost the guidance of a wise counsellor, and one who knew, perhaps better than anyone, where relief was most needed.—I am, etc.,

CHARLES J. SYMONDS,  
Honorary Treasurer.

London, W.1, June 22nd.

#### LITHOLAPAXY.

SIR,—I think Colonel L. P. Stephen, in his letter in the *Journal* of June 23rd (p. 1089), has touched on a very important subject, both from the point of view of the patient and of the State. I think that there can be no doubt of the advantages of litholapaxy over suprapubic cystotomy for the treatment of vesical calculus. There should be no need, however, to go to India for two months to learn a method which at the beginning is not devoid of risk to the patient, and which is becoming more and more out of date—at least, outside India. Litholapaxy with the cystoscopic lithotrite is safe, sure, and speedy, if practised by one expert in cystoscopy. At All Saints' Hospital, in cases of uncomplicated stone, no other method is ever used. The operation is rendered easier by employing the Ryall cystoscopic evacuator, and is easily performed under sacral anaesthesia. In the teaching hospitals litholapaxy is neither taught nor practised, and it would be to the advantage of patients if all cases of vesical calculi were transferred to the special hospitals dealing with this type of case.—I am, etc.,

F. McG. LOUGHNANE,  
Assistant Surgeon, All Saints' Hospital.

London, W.1, June 24th.

#### GASTRIC SECRETION OF NEUTRAL CHLORIDES.

SIR,—May I be allowed to defend the paper on "The origin and significance of gastric chlorides" by F. S. Hansman, Emily M. Day, and R. Clifton (from the Department of Biochemistry, Royal Prince Alfred Hospital), which was criticized by Dr. Goodhart in the *British Medical Journal* of March 24th (p. 521). Dr. Goodhart misrepresented our point of view in several details.

In the first place, we took care to state definitely that we do not deny that fluids secreted by the duodenum, pancreas, and liver may gain access to the stomach, but we maintain, and since writing the article are more than ever convinced, that all the neutral gastric chlorides cannot be accounted for on the assumption of hydro-

chloric acid of the gastric contents being neutralized by alkalis originating beyond the pylorus gaining access to the stomach, and our proof of this contention is a simple mathematical one, based on the normality of the chlorino in fluids removed from the stomach at various stages of the digestive cycle.

In the second place, Dr. Goodhart made much of the fact that we refrained from saying more than that neutral chlorides "passed" through the stomach wall. This we did because there is no definite chemico-histological proof of how the neutral chlorides do get through the stomach, but because we do not know the means that does not disprove the fact any more than in the case of hydrochloric acid itself.

As regards dilution of gastric contents, Dr. Goodhart has misunderstood our meaning. We simply stated that workers who maintain that the total gastric chlorides can be accounted for on the assumption of regurgitating alkaline fluids neutralizing the acid gastric contents have not taken into consideration that one *plus* one makes two—that is, one volume of acid gastric contents *plus* one volume of alkaline duodeno-pancreatic contents equals two volumes of resultant fluid. The chloride contents of this resultant fluid of the "pure regurgitationists" can in a very large percentage of cases be shown to be higher than could possibly be accounted for from the original hydrochloric acid, even if the acid secreted be of maximal possible normality. If Dr. Goodhart continues to refuse to accept the passage of neutral chlorides through the gastric mucosa, the onus is on him to show us where they come from.—I am, etc.,

Sydney, New South Wales, May 8th.

F. S. HANSMAN.

#### ACUTE APLASTIC ANAEMIA.

Sir.—In the *Journal* of June 16th your reviewer states that we make no attempt to substantiate our charge that his quotation is incorrect in detail. We will therefore do so. He mentioned the absence on two occasions of platelets and polymorphonuclear leucocytes. The platelets were only found to be absent on one occasion and the polymorphonuclear leucocytes were never absent. These details can be verified by reference to Table 1 on page 9. He states that similar observations to those made by us are quite frequently to be made in secondary anaemia of various types, and they cannot therefore form the basis of a diagnosis of acute aplastic anaemia. We do not know exactly what your reviewer may mean by secondary anaemia, but any case showing the complete picture recorded is not a secondary anaemia as the term is generally employed. We disagree with him as to the occurrence of all the findings described by us in a secondary anaemia, and we invite him to give any reference to a definite case of secondary anaemia which showed the same blood picture as ours. Myeloid aplasia can, of course, supervene on secondary anaemia, but the case then becomes an aplastic anaemia.

The one objection your reviewer appears to have to our diagnosis is that the haemoglobin was not sufficiently low. Does he then assert that aplastic anaemia cannot be diagnosed in its early stages? Because, if he does not, his objection is invalid. We note that he admits that "as a clinical diagnosis it is perfectly reasonable to suggest that the case was in fact one of acute aplastic anaemia cut short by treatment."—We are, etc.,

A. HAYES SMITH,  
C. J. YOUNG.

Bradford, June 17th.

\* \* Our reviewer writes: The actual figures for the two counts were 60 and 87 polymorphonuclears per c.mm.; it seems quite accurate to describe such a state of affairs as an absence of polymorphs. The authors themselves speak of the condition as "aleukia," which, being interpreted, surely means "absence" of leucocytes.

#### TREATMENT OF HARE-LIP.

Sir,—May I be allowed to correct an error in your report of the discussion on the treatment of hare-lip held at the Royal Society of Medicine on June 6th? I am reported to have said that I have "not seen good results from

primary operations" on hare-lip cases. This is obviously wrong, for everyone must have seen many admirable results from first operations, and most surgeons working in this field can lay claim to a number of very satisfactory ones.

My point, which was evidently misinterpreted, was that the object of the primary operation on any hare-lip case should be a functional closure of the cleft and that, in my opinion, "no surgeon is justified in promising a perfect cosmetic result in one operation." The more perfectly the primary operation is carried out the less need there will be for secondary cosmetic procedures, for the lip whose proper function has been established must develop naturally, and so tend to produce its own cosmetic result without further interference.—I am, etc.,

London, W.1, June 18th.

T. POMFRET KILNER, F.R.C.S.

#### Obituary.

Dr. DONALD MACGREGOR, who died in Edinburgh on June 15th, had been in practice at Jedburgh, Roxburghshire, for the past thirty-two years. He was a native of Inverness, and, after graduating in arts at Glasgow, received his medical education at the University of Edinburgh; in 1883 he obtained the diploma L.R.C.S.Ed., graduating M.B., C.M. a year later, and proceeding M.D. in 1886. In this year also he returned to Scotland and commenced practice at Denholm, removing seven years later to Jedburgh. In this town and the surrounding district he built up an extensive practice and was well known and respected over a large area in the Scottish border counties for his personal and professional qualities alike. He took an active interest in medical affairs, being a Fellow of the Obstetrical Society of Edinburgh, a member of the British Medical Association, and the author of a number of contributions to medical publications. The interment took place at Jedburgh on June 18th after a service in St. John's Episcopal Church, of which Dr. Macgregor had been a member for many years. He is survived by his widow and a married daughter; his only son was killed during the war while serving as an officer with the Gordon Highlanders.

Dr. RICHARD BLACKWELL MITCHELL, who died at a nursing home in Edinburgh on June 18th, was for twenty-eight years medical superintendent of the Midlothian and Peebles District Asylum at Roslynlee. He was a native of Orkney, and received his medical education at the University of Edinburgh, where he graduated M.B., C.M. in 1879, proceeding M.D. (with honours) in 1885. At an early stage in his career he devoted himself to the study of mental disease, becoming assistant medical officer in the Fife and Kinross District Asylum and, later, senior assistant physician under the late Sir Thomas Clouston at the Royal Edinburgh Asylum. In 1888 he was appointed medical superintendent of the Midlothian and Peebles District Asylum, and during his long service there he earned the high respect of all with whom he came in contact. In 1916 he retired and took up his residence in Edinburgh.

Dr. RICHARD TUDOR WILLIAMS, who died suddenly at Villerville, France, on June 18th, was born in 1884. He received his medical education at St. Bartholomew's Hospital, and obtained the diplomas M.R.C.S., L.R.C.P. in 1907, graduating M.B., B.S.Lond. in 1909. After holding house appointments at the Prince of Wales's Hospital and the Metropolitan Hospital, and serving for a time at sea, he commenced practice at Caergwrle, near Wrexham. His character and personality were such that he soon had a considerable connexion, which taxed his strength. During the war he served in the Royal Air Force, and for the past six years was in practice at Llanfairfechan. He was a member of the British Medical Association. Dr. Williams took a great interest in social and local affairs, being for a time a member of the town council. He was an ex-president of the Llanfairfechan Golf Club, and also of the local Liberal association. His early death is a personal sorrow to his colleagues and friends.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

IN the House of Lords, on June 21st, the National Health Insurance Bill was read a third time without debate. The House of Commons has been chiefly concerned with the Finance Bill this week. On Thursday it was asked to set up a timetable for the remaining stages of the Rating and Valuation (Apportionment) Bill. The issue of Mr. Neville Chamberlain's circular to local authorities, outlining the proposed rearrangements of their areas and powers, was expected at the end of the week.

### Parliamentary Medical Committee.

The Medical Committee of the House of Commons met on June 26th, with Dr. Fremantle in the chair. The chairman, on behalf of the committee, congratulated Sir Thomas Watts on receiving the honour of knighthood. The committee decided not to urge a reduction of the tax on petrol used in doctors' cars, as no comparable concessions were being made. It was decided that the committee should meet specially when the report of the Committee on Vaccination was published. The committee regretted that publication had been delayed. A discussion followed on the changes which the Government were contemplating in local government as these would affect hospitals, and also on the projected introduction of block grants which might cover both health and the maintenance of roads, with the consequence that money might be diverted from tuberculosis services and venereal disease measures. The possibility of Poor Law hospitals being transferred to the control of county councils was also mentioned. As Mr. Chamberlain's circular to local authorities was not before the committee it took no decisions on these topics.

### Infanticide Bill.

IN the House of Lords, on June 21st, Lord DARLING moved the second reading of the Infanticide Bill, to meet a legal anomaly defined by Mr. Justice Talbot thus: "It is a felony to procure abortion and it is murder to take the life of a child when it is born, but to take the life of a child while it is being born and before it is fully born is no offence whatever." Lord Darling said there had always been this gap in the law of England, yet the Court of Criminal Appeal had reaffirmed the doctrine of Sir Edward Coke that if injury were inflicted on a child during birth and after that injury the child was fully born and existed as a separate creature, then the person inflicting the injury might be punished. In the proposed codification of the criminal law prepared in 1879 a clause was included to deal with this defect of the law. Twenty years ago Lord Robert Cecil had introduced a bill to remedy the defect, and that bill had passed through second reading and committee, but had lapsed.

Lord PHILLIMORE supported the bill. The LORD CHANCELLOR (Lord Hailsham) doubted whether many cases of this offence had happened without punishment. Still the gap should be closed. The bill would make it an offence wilfully to kill a child in the act of birth. There were cases in which a doctor had to choose between losing the life of the mother and wilfully destroying the life of the child which was being born. Such a state of affairs must be safeguarded and protected by legislation. He was not sure that that matter was covered by the bill as drawn. He understood that Lord Darling was willing that the bill, if read a second time, should be referred to a select committee, which could consider such points.

Lord DARLING said he realized there was anxiety on the part of those who had to assist women in their accompaniment lest they should be obliged, in order that two lives might not be sacrificed, intentionally to sacrifice that of the child. That case was provided for by a clause in Lord Robert Cecil's bill as it emerged from the standing committee, and Lord Darling promised to do all he could to get that provision included in the present bill. The House of Lords then read the bill a second time and sent it to a Select Committee.

On June 26th, on the motion of Lord DARLING, the following peers were constituted a Select Committee to consider the Infanticide Bill: The Earl of Desart, Lord Phillimore, Lord Dawson of Penn, Lord Hewart, Lord Merivale, Lord Darling, and Lord Hanworth.

### National Health Insurance.

Mr. MORE-BELISHA asked the Minister of Health, on June 12th, whether he was in a position to make a statement regarding the recommendations of the Consultative Council in respect of the proposals made by the Royal Commission on National Health Insurance that the scope of the benefit should be extended to include a consultant and specialist service, and that the necessary funds for this purpose should be obtained by a partial pooling of future surpluses of approved societies. Sir KINGSLEY WOOD: The recommendations of the Royal Commission to which the hon. member refers were very fully considered by the Consultative Council, who unanimously endorsed the recommendation that the first extension of the statutory benefits of national health insurance should take the form of widening the scope of medical benefit to include a specialist and consultative service. The Council, however, by a

large majority, declined to endorse the recommendation of the Royal Commission that the cost of this extension should be met by means of a partial pooling of future surpluses of approved societies.

In England and Wales, according to an answer given by Mr. CHAMBERLAIN on June 21st, twenty-two approved societies and 275 branches, with a membership of 317,389, are not giving additional benefits. Such benefits are given by 923 societies and 6,156 branches with a membership of 13,015,180. Mr. Chamberlain is not considering any action to secure equal benefit for all persons compulsorily insured.

### Small-pox.

Answering Mr. W. Baker, on June 21st, Mr. CHAMBERLAIN said that 6,697 cases of small-pox were notified in England, including Monmouthshire, during 1928 up to June 16th. The number of deaths up to the end of May in which small-pox was medically certified as the cause or one of the causes of death was 46; the figures were provisional. No small-pox had been notified this year from a port sanitary district. He had no statistics to show what percentage of persons suffering from small-pox were casuals. Answering Dr. Vernon Davies, Mr. CHAMBERLAIN said that the total number of cases last year was about 14,000. It did not seem that this year there had been any great change in numbers. Dr. FREMANTLE asked when the report of the Departmental Committee on Vaccination would be published. Mr. CHAMBERLAIN answered that it was in print, and would be published within the next week or two. In reply to Mr. Smith Carrington, Mr. CHAMBERLAIN said the number of cases of small-pox among casuals had recently shown a tendency to decrease.

In reply to a question by Mr. Robinson, on June 21st, Mr. CHAMBERLAIN said he had received a report regarding the death of a Keighley boy, aged 10, who was vaccinated as a condition of going to a boys' camp. The Ministry of Health had communicated with the certifying practitioner. No *post-mortem* examination was held, and the certified causes of death were: (1) (a) acute meningitis, (b) tonsillitis; (2) vaccination.

### Slum Clearance Schemes.

IN the House of Lords, on June 20th, the BISHOP OF SOUTHWARK opened a discussion on slums. He asked how many persons would be affected by slum clearance schemes approved by the Ministry of Health but not yet carried out, and whether the Government had any proposals to hasten the abolition or improvement of slum property. They were told that in London, apart from 26,000 people who had been or would be dealt with under slum clearance schemes adopted by the London County Council, at least 100,000 people were living under insanitary conditions. He hoped the Government would, in the near future, do its utmost to remove the slums.

Lord GORELL quoted from reports by medical officers to the effect that the housing shortage and the slum problem were as acute as ever.

Lord GAGE, replying for the Government, said that in the last year for which statistics were available over 1,000,000 houses were inspected for defects; 13,260 were found to be unfit for human habitation and 352,643 were found unfit in minor respects. As a result of action by local authorities in 1926, 600,000 houses were repaired and put into a correct sanitary condition. Since the previous 6,600 new houses had been completed to replace houses demolished or to be demolished. These new houses would accommodate 29,000 or 30,000 persons. Since the war 123 slum schemes had been submitted and 113 confirmed. In the vast majority of clearance schemes considerable work had already been carried out. Of persons displaced by such schemes, about 39,000 had still to be provided for.

Lord BEAUCHAMP spoke of the prevalence of overcrowding in many districts. Infantile mortality, he declared, was 20 per cent. in bad areas and 11 per cent. in good areas.

Lord SALISBURY said he would convey to the Minister of Health the suggestion that the Town Planning Acts should be extended to existing houses to prevent overcrowding by the conversion of dwellings into places of business. The Government was considering whether they could not find a better remedy than the vast schemes of slum clearance and rebuilding. The reconditioning of suitable houses would be cheaper and more speedy.

Sir KINGSLEY WOOD, on June 25th, replying in the House of Commons to Mr. Hurd, said the Minister of Health had not received from the recent conference of local authorities on housing a resolution asking for a return from local authorities of low-standard working-class dwellings in their areas, distinguishing between those houses capable of being reconditioned and those which, because of total unfitness, should be condemned. He was reluctant to add to the burdens of local authorities in the preparation of returns.

### Welsh Board of Health.

In reply to Sir C. Kinloch-Cooke, on June 25th, Sir KINGSLEY WOOD said that on the retirement of Sir Thomas Hughes from the chairmanship of the Welsh Board of Health, the position was reviewed, as was the case from time to time with all sections of the Ministry of Health. This review showed that the bulk of the Board's work was done satisfactorily by the members in their individual capacity, and meetings of the Board for collective deliberation were rarely held. In these circumstances the Minister of Health felt that the employment of four higher officers on the Board was no longer justified, and that the work could be done by three. The Ministry of Health Act, 1919, empowered the Minister to appoint such officers as he thought fit to constitute a

board of health in Wales, and it neither specified any number nor laid down that there should be any chairman. Sir C. KINGSLEY WOOD asked if Sir Kingsley Wood was aware that the abolition of this post was causing indignation, and whether the Minister of Health would receive a deputation on the subject. Colonel WOOLCROFT asked what saving would be effected by the abolition of this post. Sir KINGSLEY WOOD said he believed there would be a saving of about £1,600 a year. If any indignation had arisen over the action of the Minister of Health it was due to misapprehension. Replying to Mr. Morris, Sir KINGSLEY WOOD said the effect of the abolition of the post was not to place the Welsh nation under the jurisdiction of the English Commissioners. The Welsh Board had met on an average only three times yearly. The Minister of Health believed that the duties of the office would be carried on efficiently.

On June 26th Sir KINGSLEY WOOD stated that the saving realized by the recent reorganization of the establishment of the Welsh Board of Health was £1,628.

#### Liquor (Disinterested Ownership and Management) Bill.

Speaking on June 26th, in the House of Lords, on a motion for the second reading of the Liquor (Disinterested Ownership and Management) Bill, moved by Lord Balfour of Burleigh, Lord Dawson of Penn said that the principle of local option carried with it certain disadvantages, not to say dangers. The institution of elections for this or that matter must cheapen elections in the eyes of the people. Experience in regard to elections for boards of guardians and under the Scottish Temperance Act showed that relatively small numbers of people went to the polls. Everyone interested in social reform rejoiced that they had the valuable experiment at Carlisle, but after twelve years, with every advantage, it could not be said that Carlisle was an outstanding success. He could see no end to these *ad hoc* bodies. Possibly they would have the New Health Society asking to have local option in the use of brown bread. Legislation on drink had proved, that unless legislators carried the people with them they defeated their own objects. Education and sanitation had done far more than legislation to promote temperance in this country. The improvement in temperance began long before the war, and the figures showed a steady improvement in that respect among the masses of the people. Nothing was more striking than the rapid and progressive improvement in the temperance of the people. He would give one set of figures which showed that in a large fully licensed house in London 75 per cent. of the people who sat there on one evening were consuming no alcohol at all. The only place where drunkenness seemed entrenched was from time to time behind the motor wheel. The statesmanlike course to pursue if they wanted to increase temperance was to study the causes which worked for temperance, and further them wherever possible. Among those causes was the growth of knowledge through education. The educational propaganda of the last twenty-five years had done a great deal. Another cause was the growth in popularity of recreation and games. Above everything else there was the love of health and fitness. There was the realization of how good alcohol was in its right place and how they ought not to drink too much, and there was growing up a degree of temperance which left little to be desired. There had been a striking improvement in the public houses in this country wherever one went, with the exception of the slums. In some of the newer houses around London food and coffee were provided, and non-alcoholic drinks, with games and amusements, and the management were not paid any commission on the amount of alcoholic drink. Along such lines as these they ought to proceed.

The motion for the second reading of the bill was defeated by 67 votes to 24.

#### Slaughter of Animals (Scotland) Bill.

The House of Commons, on June 22nd, considered the Slaughter of Animals (Scotland) Bill, and passed it through report and third reading. The bill proposes to make the use of the humane killer compulsory for the slaughter in Scotland of cattle, calves, sheep, and lambs, but not of swine. An amendment to allow young lambs and calves to be killed by the knife was defeated. General CHARTERIS referred to an experiment conducted by the chief veterinary officer of Edinburgh, and attended by two independent scientists of Edinburgh. This experiment had determined that from the time when the first incision of the skin was made by the bullet from the captive bolt of the instrument there elapsed no more than four-fifths of a second until complete unconsciousness supervened. With the knife the time was thirty-three and one-fifth seconds. With the humane killer unconsciousness was, for all intents and purposes, instantaneous.

Dr. DAVIDSON SMITH said that sheep required the use of the humane killer more than any other animal.

Dr. ELLIOT (Under Secretary for Scotland) said the Government regarded the bill as an instalment of legislation applicable to the United Kingdom.

**Experiments on Animals.**—On June 26th, in reply to Mr. Maclean, Sir W. JOHNSON-HICKS said that in 1927 there were 13,871 experiments on animals with anaesthetics and 279,431 without anaesthetics. The latter class of experiments were mostly inoculations and feeding experiments, and in no case was an operative procedure more severe than simple inoculation allowed without an anaesthetic. In 1927 there were 253 places registered for conducting experiments in vivisection, and 1,230 persons were licensed to conduct them; 7,647 experiments were performed under certificate B (that is where the experimenter is relieved from the obligation to kill the animal before it recovers from the anaesthetic). Of these, 583 were on cats and dogs.

**Treatment of Tuberculous Pensioners.**—In a reply, on July 21st, to Sir Wilfred Sugden, Major THOMSON said treatment for pensioners suffering from tuberculosis was secured through the local health authorities, who normally made use of their own sanatoriums, approved for the purpose by the Ministry of Health. This practice ensured that local facilities were utilized to the full and was also consistent with the policy of treating pensioners, as far as possible, near their own homes. Cases of this class likely to be suitable for, and to benefit from, ultimate residence in a village settlement after any course of treatment required, would be increasingly few among pensioners whose tuberculosis was directly traceable to their war service, having regard to the stage of their complaint, age, previous occupation, habits of life, and other factors. When such cases arose treatment in a sanatorium attached to a village settlement might be preferable to the normal arrangements of treatment in the sanatorium of the local health authority, and he was prepared to continue to give reasonable facilities for the treatment of suitable cases. There were excellent local sanatoriums in the North of England, and the Ministry of Health desired to make full use of them.

**Death of a Radiographer from Cancer.**—Dr. VERNON DAVIES, on June 25th, asked the Prime Minister whether, in view of the facts disclosed by the inquest held on June 19th at Deptford, on the body of Arthur Augustus Parsons, radiographer at the Seamen's Hospital, Greenwich, for over twenty years, and for six years previously at Westminster Hospital, who died from carcinoma contracted in the course of his duty, he would consider recommending some appropriate method by which the State could show its appreciation of such work for the public good. Mr. BALDWIN said that if Dr. Davies sent him full particulars of this case he would look into it.

**Petrol Tax.**—The House of Commons, in Committee, on June 25th, considered the petrol tax. Mr. Snowden moved to reduce the tax from 4d. to 1d. This amendment was resisted by Mr. Churchill, and defeated by 237 votes to 115.

#### Notes in Brief.

On June 25th Mr. Baldwin stated that it was not proposed to make any alteration in the status of the Ministry of Pensions during the life of the present Parliament.

The effect of coal dust in causing chest diseases among surface workers at collieries is being investigated.

## Universities and Colleges.

### UNIVERSITY OF OXFORD.

#### Radcliffe Prize, 1929.

THE next award for the Radcliffe Prize will be in the year 1929. The prize, of the value of £50, is awarded by the Master and Fellows of University College, Oxford, every second year for research in any branch of medical science comprised under the following heads: human anatomy, physiology, pharmacology, pathology, medicine, surgery, obstetrics, gynaecology, forensic medicine, hygiene. It is open to all graduates of the University of Oxford who have proceeded, or are proceeding, to a medical degree in the University. Candidates must not have exceeded twelve years from the date of passing the last examination for the B.A. degree, and must not, at the date of application, be Fellows or the Foundation of Dr. John Radcliffe. Candidates must send in their memoirs to the Secretary of Faculties at the University Registry, Oxford, by December 1st, 1928. The award will be made in March, 1929. No memoir for which any University Prize has already been awarded is admitted to competition for the Radcliffe Prize, and the prize will not be awarded more than once to the same candidate.

### UNIVERSITY OF CAMBRIDGE.

At a congregation held on June 19th the degree of Doctor of Medicine was conferred on W. D. Keyworth.

A congregation for the conferment of degrees in medicine and surgery will be held on July 21st, at 2 p.m.

The A. R. Graham prize in medicine has been awarded to J. Metcalf.

The following candidates have been approved at the examinations indicated:

THIRD M.B., B.CHIR.—(Part I) *Surgery, Midwifery, and Gynaecology*: M. E. Albury, N. R. Barrett, H. F. Bateman, W. A. G. Bell, P. Bash, S. S. Chester, R. Clayton-Jones, G. C. Dewes, A. J. Dix Perkin, W. G. Drake-Lee, S. G. Elkin, W. A. Elliston, P. H. Fox, Hodkinson, S. H. G. Hamfray, S. D. A. Lankester, P. G. Levick, J. O. F. A. Miles, J. K. Moore, J. R. Peacock, L. S. Penrose, J. B. A. Reynolds, A. M. Rhydderch, A. M. Roberts, W. H. Scott-Easton, C. W. Shaw, H. J. Simmonds, W. H. Simmonds, E. T. O. Slater, T. R. Stevens, H. H. Stewart, H. S. Taylor Young, J. F. Varley, J. Vearhan Bradley, H. S. Waters, L. B. Winter, F. W. J. Wood. *Women*: M. H. D. Carr, M. Leathes, J. R. Lees, M. A. Wilcox. (Part II) *Pathology and Pharmacology*: Barrett, D. H. Balfrage, W. V. G. Drake-Lee, J. S. G. Elkin, S. G. Elkin, J. O. F. A. Miles, J. K. Moore, J. R. Peacock, L. S. Penrose, J. B. A. Reynolds, A. M. Rhydderch, A. M. Roberts, W. H. Scott-Easton, C. W. Shaw, H. J. Simmonds, W. H. Simmonds, E. T. O. Slater, T. R. Stevens, H. H. Stewart, H. S. Taylor Young, J. F. Varley, J. Vearhan Bradley, H. S. Waters, L. B. Winter, F. W. J. Wood. *Women*: M. H. D. Carr, M. Leathes, J. R. Lees, M. A. Wilcox. *Pathology and Pharmacology*: Barrett, D. H. Balfrage, W. V. G. Drake-Lee, J. S. G. Elkin, S. G. Elkin, J. O. F. A. Miles, J. K. Moore, J. R. Peacock, L. S. Penrose, J. B. A. Reynolds, A. M. Rhydderch, A. M. Roberts, W. H. Scott-Easton, C. W. Shaw, H. J. Simmonds, W. H. Simmonds, E. T. O. Slater, T. R. Stevens, H. H. Stewart, H. S. Taylor Young, J. F. Varley, J. Vearhan Bradley, H. S. Waters, L. B. Winter, F. W. J. Wood. *Women*: M. H. D. Carr, M. Leathes, J. R. Lees, M. A. Wilcox.

## UNIVERSITY OF LONDON.

SIR GREGORY FOSTER has been elected Vice-Chancellor for 1928-29, in succession to Sir William Boveridge.

The degree of D.Sc. in Anatomy has been conferred upon Miss I. C. Mann, and that of D.Sc. in Physiology upon Mr. C. H. Best. Dr. J. Fawcett has been appointed the representative of the University at the fourteenth annual conference of the National Association for the Prevention of Tuberculosis, to be held in London in October next.

## UNIVERSITY OF GLASGOW.

A GRADUATION ceremony was held on June 20th, when the following were among the degrees conferred:

HON. LL.D.—Professor G. W. Crile, F.R.C.S. (Cleveland, Ohio).  
M.D.—F. R. Martin.

## QUEEN'S UNIVERSITY, BELFAST.

THE results of Queen's University final examinations, held in June, show an unusually high percentage of passes. For the degree of M.D. seven candidates were successful, representing 75 per cent. of the total number of candidates; while forty-five candidates were awarded the degrees of M.B., B.Ch., B.A.O.—approximately 70 per cent. of those who sat for the examination. The following is a list of the successful students:

M.D.—\*H. W. Black, \*J. S. Campbell, \*J. C. Davison, H. Harris, \*W. F. T. M'Math, R. A. Reynolds, L. Walker.  
M.B., B.Ch., B.A.O.—\*A. J. P. Alexander, \*F. F. Kane, \*W. W. Bassett, \*J. H. Biggart, \*J. A. D. Deeny, \*Eileen M'C. Hill, \*H. C. Lindsay, \*S. Anderson, \*T. H. Baillie, \*Martha E. Cantley, \*F. W. H. Caughay, \*H. M'B. (husband), \*H. H. Collier, \*J. De Lary, \*G. B. W. Fisher, \*J. H. Getty, \*A. D. Glasgow, \*M. J. Gordon, \*S. E. V. Gordon, \*J. Gourley, \*Margaret M. Hosoy, \*Mary E. Houston, \*T. S. Hoy, \*D. J. Hurrell, \*M. Jeffers, \*Elizabeth H. J. Kelly, \*J. M. Kennedy, \*J. S. Kyle, \*A. E. Lavelle, \*K. N. Lavelle, \*W. J. Ludlow, \*W. E. Lyster, \*C. B. M'Carthy, \*W. N. M'Cuilough, \*W. H. M'Ilrath, \*Margt. M. MacNeill, \*Jane E. McNeill, \*W. Morton, \*Alice I. Muir, \*J. Pitt, \*M. Rossefield, \*W. J. Stewart, \*Nora E. Stoupe, \*A. M. Wallace, \*F. L. Wynne.

\*Gold medal.

†With commendation.

†First-class honours.

‡Second class honours.

## SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY—K. J. M. Graham, T. A. P. Proctor, A. F. Quarby, S. M. Rahman, W. Ziv.  
MEDICINE—P. C. Basu, H. C. Clifford-Smith, S. M. Rahman.  
FORENSIC MEDICINE—M. K. Bryce, A. F. Quarby.  
MIDWIFERY—H. H. Jackson, C. P. Madden, H. Murkis.  
The diploma of the Society has been granted to Messrs. K. J. M. Graham and W. Ziv.

## The Services.

## INDIAN MEDICAL SERVICE.

## ANNUAL DINNER IN LONDON.

THE annual London dinner of the Indian Medical Service was held at the Trocadero Restaurant on June 20th, when Major-General Sir R. Havelock Charles, Bt., G.C.V.O., K.C.S.I., was in the chair. The following is a list of the officers present:

Major-Generals: B. N. Deane, C.I.E., A. A. Gibbs, K.H.P., C. F. A. Harris, C.S.I., R. W. S. Lyons, Sir R. C. MacWalt, C.I.E., J. B. Smith, C.B., C.I.E.  
Colonels: J. Crammin, V.C., C.B., C.I.E., V.D., H. M. Cruddas, C.M.G., O.B.E., C. M. Goodbody, C.I.E., D.S.O., T. A. Grainger, C.M.G., C. R. N. Green, J. A. Hamilton, C.M.G., H. Kellock McKay, C.B., C.I.E., A. J. Macnab, C.B., C.M.G., R. A. Noedham, C.I.E., D.S.O., J. J. Pratt, R. G. Turner, C.M.G., D.S.O., F. Wall, C.M.C., C. N. G. Wimberley, C.M.G.  
Lieutenant-Colonels: A. W. Alcock, C.I.E., F.R.S., W. G. P. Alpin, O.B.E., J. Anderson, C.I.E., S. T. C. C. . . . . E. K.H.P., Sir Frank Connor, D.S.O., A. G. . . . . M. Crawford, O.B.E., R. H. Elliot, G. H. Fro . . . . . C.I.E., E. C. Hepper, E. C. Hodgson, D.S.O. . . . . J. B. Hunter, O.B.E., S. P. James, Davenport . . . . . W. H. Leonard, T. M. Macrae, O.B.E., J. Mas . . . . . J. Miller, F. O'Keefe, C.I.E., C.V.O., J. S. O'Neill, M.C., Sir Leonard Rogers, C.I.E., F.R.S., E. R. Rost, O.B.E., S. Browning Smith, C.M.C., R. Steen, Ashton Street, W. A. Sykes, D.S.O., D. W. Sutherland, C.I.E., G. Thomson, C. Sloan, Thomson, W. H. Thornhill, E. L. Ward, C.I.E., D. P. Warhner, A. C. Younan.  
Majors: Norman Briggs, Sir T. J. Carey-Evans, M.C., H. S. Cormack, M.C., A. W. Duncan, P. K. Cilroy, M.C., N. H. Hume, M. L. C. Irvine, J. C. John, O.B.E., R. N. Kapadia, M.C., G. Rigby Lynn, D.S.O., V. Mahadevan, M. B. Mehta, R. V. Morrison, M. A. Nicholson, M. J. Quirke, M. A. Rahman, J. Rodger, M.C., E. C. A. Smith, H. Tait Caldwell, M.B.E., D. R. Thomas, C. Y. Thomson, F. R. Thornton, M.C.  
Captains: M. P. Atkinson, D. P. Bhargava, J. E. Gray, A. C. Hayden.  
Lieutenant: F. T. Harrington.

## COMMISSIONS IN THE R.A.M.C.

THE War Office announces that a limited number of commissions in the Royal Army Medical Corps are being offered to qualified practitioners under 28 years of age. There will be no entrance examination, but candidates will be required to present themselves in London for interview and medical examination. Applications should reach the War Office not later than July 20th. In the meanwhile, all information as to conditions of service and emoluments may be obtained from the Under Secretary of State, War Office (A.M.D.I), Whitehall, London, S.W.1.

## DENTAL OFFICERS R.N.

The gold medal for candidates on entry as dental officers R.N. has been awarded to W. Holgate, surgeon lieutenant (D).

## Medical News.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on Tuesday, July 3rd, Mr. G. Perkins will give a demonstration at the Brockley Hill Country Orthopaedic Hospital at 11.30 a.m. If not less than ten post-graduates notify their intention to be present by telephone to Mayfair 2236. Demonstrations will be given at the Royal Westminster Ophthalmic Hospital on Thursday, July 5th, at 3 p.m., by Mr. M. T. Hine, and at Charing Cross Hospital on Friday, July 6th, at 2 p.m., by Dr. F. G. Chandler: they are open free to members of the medical profession. There will be a special whole-day course at the Prince of Wales's Hospital in medicine, surgery, and the specialties from July 9th to 21st, and a course in proctology from July 9th to 14th at St. Mark's Hospital. Later summer courses are as follows: At the Queen Mary's Hospital in medicine, surgery, and the specialties from August 27th to September 8th; in diseases of the chest at the Brompton Hospital, July 30th to August 4th; in diseases of infants at the Infants' Hospital, August 13th to 25th; in urology at the All Saints' Hospital, August 7th to September 1st. Full particulars, syllabuses, etc., may be had from the Fellowship at 1, Wimpole Street, W.1.

THE annual meeting of the Royal Medico-Psychological Association will be held on July 11th, 12th, and 13th at the West Riding Mental Hospital, Wakefield, under the presidency of Professor J. Shaw Bolton, M.D. On the afternoon of the first day the president will give his address entitled "The evolution of a mental hospital—Wakefield, 1818-1928," and the Gaskell medal and prize for 1927 will be presented to Dr. Elizabeth Casson, and for 1928 to Dr. F. R. Martin. The morning and afternoon sessions of July 12th and 13th will be given up to papers and demonstrations. The general secretary is Dr. R. K. Worth, Springfield Mental Hospital, nr. Tooting, S.W.17.

AT a special meeting of the Royal Anthropological Institute, to be held at 52, Upper Bedford Place, Russell Square, W.C., at 8.15 p.m. on Tuesday, July 3rd, Dr. E. H. Hunt will give an address on the rock-hewn temples of Ajanta and Ellora. On the afternoon of that day, from 2 o'clock, a series of exhibits illustrating the paper—photographs, maps, etc.—will be on view at the Institute. Among them will be photographs of self-mutilation ceremonies and implements of the Raha fakirs of Hyderabad.

A COMPLETE post-graduate course in dermatology and venereology will be held at the clinic for cutaneous and syphilitic diseases at Strasbourg from September 17th to November 3rd. There will also be a laboratory course, including twenty lectures and practical work. The fee for each course is 300 francs. Further information may be obtained from Professor L. M. Pantrier, 2, Quai St. Nicolas, Strasbourg.

ACCORDING to a report issued by the Health Organization of the League of Nations, there has been a great decrease in the incidence of small-pox in European countries during recent years. The only exception to this general rule is offered by Great Britain, where there has been a steady increase in the number of cases officially reported since 1920. In 1927 there were 14,931 cases in Great Britain, as compared with 6,841 in the rest of Europe. The disease is common only in a mild form, known as alastrim, but this mild form has been notably absent from Continental Europe, with the exception of Switzerland, where between 1921 and 1926 it persisted in epidemic form. In 1927, however, no cases were reported in that country. Despite the large number of cases in Great Britain, the mortality has been very low, no deaths having occurred in Scotland between 1922 and 1927, and only 49 deaths in 1927 in England and Wales. During the period under review the disease was limited largely to the North of England and the Midlands. Of 10,141 cases reported in 1926, 10,070 were reported from Durham (6,645), Yorkshire (1,270), Derbyshire (982), Northumberland (843), Nottinghamshire (191), and Lancashire (139). During the winter of 1927-28 a wider diffusion of infection occurred; 4,711 cases were reported from 38 counties in England and Wales in the first quarter of 1928, but the mortality has been almost negligible. The report states that vaccination within ten years appears to give complete immunity to the disease. Thus in 1926 there was not a single case among children below 12 years of age who had been vaccinated in infancy, whereas there were no fewer than 3,980 cases among children below 12 years of age who had never been vaccinated. That part of the report dealing with Russia shows a remarkable decrease in the number of cases since the war. In 1919 there were 186,755 cases, which gives a rate of 30 for every 10,000 inhabitants; in 1926 there were only 16,547, or 1.1 to every 10,000 inhabitants; in 1913 there were 4 cases to

every 10,000 inhabitants. No case of small-pox was reported in Bulgaria, Czechoslovakia, Denmark, Gibraltar, Hungary, Lithuania, Luxembourg, Malta, or Rumania in January or February of this year.

The annual National Conference on Maternity and Infant Welfare will be held at the Guildhall, London, on July 5th and 6th. In addition to Sir George Newman, Dame Janet Campbell, and other representatives of the Ministry of Health there will be present Dr. Helen MacMurchy, chief of the Child Welfare Division of the Canadian Department of Health; Sir Frederick Truby King, director of child welfare for New Zealand; Dr. Jamshyd Munsiff, chief of the Public Health Department, Bombay; and Dr. Ruth Young of the All-India League for Maternity and Child Welfare. We understand that so great has been the demand for tickets that all the seats in the council chamber of the Guildhall have been allotted.

The Hampstead Garden Suburb, which, with other more or less similar schemes for the deliberate creation of new social and communal units, has exercised a considerable influence on the ideas associated with town-planning, is now celebrating the twenty-first anniversary of its inauguration with a week of entertainments and other festivities. The Earl of Lytton performed the opening ceremony on June 23rd, when Sir Philip Cuscliffe-Lister presided.

The Austrian State Publishing Office (Österreichische Staatsdruckerei) Wien I, Seltzerstrasse 24, has published in the German language a reference book on Austrian spas, which is obtainable direct or through any bookseller. It contains much information concerning the various spas, the composition of their mineral waters, and their therapeutical effects. The book has been compiled by well-known Austrian authorities, such as Professor Viktor Conrad, Dr. Karl Diem, Dr. Josef Knett, Professor Hans Horst Meyer, and Dr. Siegfried Steckmayer.

THE American Red Cross Society in April officially closed its relief work for victims of the Mississippi Valley floods, the largest task it has ever undertaken, after a year of strenuous endeavour. In all over 600,000 refugees came under the society's care, and practically all the relief fund raised, amounting to about £3,400,000, has been expended.

M. MAX HUBER, a judge of the Permanent Court of International Justice at the Hague, has been elected to succeed the late M. Gustave Ador as president of the International Red Cross Committee.

THE Minister of Health (the Right Hon. Neville Chamberlain, M.P.) will open the Surrey County Sanatorium at Milford, on Friday, July 20th, at 3.30 p.m. The sanatorium has been designed to accommodate 300 patients and staff at a cost of about £200,000.

THE President of the French Republic has conferred the Cross of Officer of the Legion of Honour on Professor G. H. F. Nuttall, Cambridge; Professor P. Rondopoulou of Athens, editor of *Iatriki Proodos* and *La Grèce Médicale*, has been nominated a Chevalier of the Legion; and Dr. Truc, honorary professor of the Montpellier Faculty of Medicine, has been nominated Commander.

DR. NICHOLAS D. DUNSCOMBE, assistant medical officer of health for Southampton, has been called to the Bar by the Inner Temple.

AS announced in our advertisement pages the Association of Surgeons of Great Britain invite applications for a surgical scholarship of the value of £350 for one year. Applications must be sent to the secretary, 17, Wimpole Street, W.1, by September 30th.

THE forty-third volume of the *Archiv für Verdauungskrankheiten* has been dedicated to the editor, Professor I. Boas, on the occasion of his seventieth birthday. The sixty-eighth volume of the *Monatsschrift für Psychiatrie und Neurologie* has been dedicated to the editor, Professor K. Biquhofer, on his sixtieth birthday, and a like compliment has been paid by *Dermatologische Zeitschrift* to its editor, Professor Eric Hoffmann. A special number of the *Archiv für Verdauungs- und Störungen* has been dedicated to Professor H. ... on attaining the same age.

THE Association of Medical Officers of Missionary Societies has issued a new edition (the fourth) of its pamphlet, *Health Instructions for Missionaries in the Tropics*, which conveys much useful information in a small space. A section is given to emergency treatment, and there is a brief supplement for women. Copies are obtainable from the honorary secretary of the association, 1, Farnley Road, E.4, price 4d. each, or 3s. per dozen (inland post free).

DRS. H. T. CHARLIS and John Willett have been promoted Commanders in the Order of the Hospital of St. John of Jerusalem, and Drs. William Blackwood and William Owen Evans have been appointed officers.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9561, 9562, 9563, and 9564** (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:  
EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 10, South Frederick Street, Dublin (telegrams: *Basillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

## QUERIES AND ANSWERS.

### INCOME TAX.

"F. G. D." bought a car in 1921 for £595, and has now replaced it by a slightly different type of car at a cost of £295, less £17 allowed for the old car. What claim can he make?

For the year 1928-29 he should claim the depreciation allowance on the written-down value as at December 31st, 1927, of the old car—say, £220 at 15 per cent., £33. This will help to pave the way for the allowances to be claimed for 1929-30, which will be (1) obsolescence allowance—that is, £295—£17—£33=£245, and (2) depreciation allowance, £295 at 15 per cent.—that is, £44.

### Gift of Car for Professional Use.

"H. B. L." bought a second-hand Hillman coupé in 1922 for £385. In 1927 he received as a present a Hillman all-weather (1925) car in exchange for the coupé. The value of the former when given was £170 and the latter was sold immediately for £60. The depreciation allowed on the coupé has been: 1925-26 £42, 1926-27 £35, and 1927-28 £30. What should he claim as the depreciation allowance for 1928-29?

Apparently the last depreciation allowance reduced the written-down value to £170. On that basis the depreciation for 1928-29 will be as follows:

Value of car brought forward	£170
Deduct realization value of car replaced	60
	£110
Add value of car acquired	170
	£280
Allowance at 15 per cent.	£42

### Cash Receipts Basis.

"T. H. G." bought an additional practice as from April 1st, 1927, and took in a partner, who acquired one-third share in the combined practices. Book debts were not taken over on either purchase. Past returns have been on the cash basis. Are the expenses incurred in connexion with the proprietorship changes allowable?

The cash basis is justified by convenience only, and is applicable only where the amount received in the year is probably equal to the value of the gross bookings. In the circumstances stated "T. H. G." cannot require his "cash basis" returns to be accepted, and the accounts for 1927-28 should be based on the gross bookings for that year less a deduction, which should be carefully arrived at after a specific valuation of each outstanding debt, for probable losses by bad debts. Cash received for pre-April, 1927, bookings is not liable to tax, because *ex hypothesi* the tax on those earnings has already been accounted for—on the basis of the assumption that the cash receipts represented the true earnings of past years. The expenses of purchase and formation of the partnership are not allowable; they are of a "capital" nature.

*Assistant becomes a Partner.*

"J. L." was an assistant in the employment of A and B until January 1st, 1928, when he became a partner, taking one-fourth share of the profits. On what basis should he return for 1928-29 be made?

\* \* The change in status involves a radical change in the assessment. For 1928-29 he is no longer assessable under Schedule E as an employee of the firm, but for the whole of that year under Schedule D in respect of professional profits. Strictly it is the firm of A, B, and J. L. which is chargeable; he is, not individually assessable. Consequently the new firm will return, and be assessed on the basis of the profits of the old firm for 1927, and one-quarter of that will be attributable to "J. L." and will represent his gross liability. The firm gain, because "J. L.'s" salary will have been deducted in calculating the profits for 1927, but it will not be assessable for 1928-29.

**STATUS EPILEPTICUS.**

"H. C. B.'s" inquiry regarding the treatment of this condition in a child, published on June 23rd (p. 1097), stated, through an error in transcription, that the violent (convulsive) stage of the attacks usually lasted two hours; this should have read "twenty-four hours."

**LETTERS, NOTES, ETC.****LEAD TREATMENT OF MALIGNANT DISEASE.**

DR. J. McNAMARA (Kensington, W.) writes: May I appeal for a fair trial of Professor Blair Bell's lead treatment of cancer? That treatment is the result of over twenty years' investigation, and there is no getting over or explaining away the statistics given by Professor Cunningham in a paper read at the Nottingham meeting of the British Medical Association and published in the *British Medical Journal* of November 20th, 1926. Professor Cunningham showed that of 227 patients suffering from malignant growths between 30 and 40 were cured by lead. Some time ago I heard that there was to be exhibited at a medical meeting in a London hospital a patient undergoing the lead treatment. Having a special interest in the treatment, I went to see the patient before the meeting and learned all the details. At the meeting the patient was shown by a young man, who simply said, "This is a patient undergoing the new lead treatment, and all I can say is that it has done no harm and has done no good." He never mentioned that the treatment had only just begun and that the preparation of lead used was different from that used by Professor Blair Bell. Is this fair? Ideas originating outside London do not seem at first to be accepted with much enthusiasm in the metropolis. Witness the struggle of Listerism to get a footing in the capital. When Dr. Coley of the Cancer Hospital of New York came over here and published his claim that his fluid could cure at least 10 or 12 per cent. of otherwise hopeless cases of sarcoma a half-hearted trial was given to the treatment, but the fluid used was made in London and was not Coley's fluid at all. The result, of course, was disappointing, and gave in this country a knock-out blow to the treatment, from which it has not yet recovered. Nevertheless, Coley's claim is, beyond all doubt, valid. A near relation of my own suffering from round-celled sarcoma of the breast, which recurred after operation, was saved by it. In Sir Jonathan Hutchinson's polyclinic I saw two cases of large inoperable sarcomas cured by Coley's fluid. Sir Victor Horsley once said something about our being different from what we were formerly. He said it used to take twenty years to get an idea into our heads and now it only takes ten.

MR. J. PATTERSON (Crouch End, N.3) writes: In the *British Medical Journal* of June 23rd (p. 1088) Professor Blair Bell says that I originally made my lead iodide preparation on his instructions, when I was working for him in Liverpool. This is not accurate. I first made my lead iodide preparation in May, 1920, more than six months before I gave up all other work to go to Liverpool to take sole charge of the chemical work of his cancer research. Professor Blair Bell suggested to me the preparation of a lead body, and I tried the iodide. This preparation was used on patients at Liverpool before I joined his staff there. Since leaving Liverpool—with regret expressed in writing by both parties to the separation—I have succeeded in improving my preparation. Such success as I have attained is largely due to the kindness of Dr. Drakeley, head of the chemical department, Northern Polytechnic Institute, who put at my disposal all the resources of his department. He also gave me free access to his own private reagents.

**PNEUMONIA AFTER OPERATION FOR GASTRIC AND DUODENAL ULCERS.**

MR. R. CHALMERS, M.D., F.R.C.S. Ed. (Assistant Surgeon, Green Bank Hospital, Darlington), writes: In the *British Medical Journal* of June 23rd (p. 1055) Mr. Strong Heaney's report on the results of operation in a series of the above cases emphasizes again the dreadful toll that chest complications, particularly pneumonia, takes of these cases, and robs the surgeon of the success his efforts and skill deserve. I wish here to record the very successful, almost dramatic, results which followed, in a case of pneumonia after operation for acute perforating ulcer of the stomach, from the use of a vaccine made from Wynn's formula, and given in the large doses he recommends, as soon as

the pneumonia became evident. The case was that of a young man, admitted to hospital thirteen hours after an ulcer near the pyloric end of the stomach had perforated. As it was high up in the portal fissure it was closed with difficulty, omentum being required to seal it over; drains were inserted laterally into Morrison's and suprapubic pouches on second day. Consolidation of the left lower lobe appeared, while the right lower lobe was in a doubtful condition. A few hours after the first injection of the vaccine the patient had taken a turn for the better, his skin was moist, and he expressed himself as feeling much better, if it could only get some sleep. This was procured by a hypodermic injection of heroin; other two doses of the vaccine were given on successive days. Thereafter his recovery was rapid and uneventful. Inquiry for a further supply of this vaccine resulted in the information that the makers (Messrs. Parke, Davis and Co.) had discontinued its manufacture; there was such a small demand for it that it did not pay for the cost of production. This is very unfortunate.

**A SURGICAL PORTRAIT GROUP.**

DR. A. E. WINTER (11, Oakfield Road, Clifton, Bristol) writes: Thirty years ago I had prepared for me a photograph from the picture of the Council of the College of Surgeons (1834) and distributed fifty of the copies over the Empire gratis. There are a few still remaining, which can be obtained from me for schools, universities, or institutes of medicine with students in the English-speaking world, preferably those of Africa or America, since the Empire has already many. The portraits in the group include Sir Spencer Wells (abdominal surgery), Lord Joseph Lister (asepsis, antiseptics), and W. G. T. Wells, Boston, U.S.A. (anaesthetics), who represent and symbolize the advances made in surgery during the Victorian era.

**ENDOCARDITIS IN YOUNG CHILDREN AND LAMBS.**

DR. G. ARMOUR STEPHENS (Swansea) writes: I desire to draw the attention of provincial members of the Association to condition of the heart found in undernourished lambs, in the hope that some of them may test my observations. In large flocks it is well known that many lambs are undernourished because, at a time when they are unable to eat much grass, they cannot obtain a proper supply of milk from their mothers. On examining the hearts of such lambs I have found that there is an inflammatory fringe on the edge of the mitral valve and a smaller one on the tricuspid, while the heart muscle is pale and softer than normal.

Milk, as a time-containing food, is necessary for the growth of bone and the development of blood, and, if the supply is reduced, both suffer. The fact which I have been trying to emphasize—namely, that heart disease occurs only in children who do not get milk (while possessing a perverted appetite for acids such as vinegar)—seems to be corroborated by my observations in connexion with lambs. In both cases the blood lacks proper nourishment, with the result that the interaction between the leucocytes and the endothelium of the blood vessels of the valves is so interfered with as to give rise to an inflammatory exudation there. To what extent the lowered vitality of the lambs under these conditions must be associated with a poison introduced by an insect or an intestinal parasite I am not certain, though I am satisfied that such has undoubtedly a marked determining influence in connexion with the development of endocarditis. This is made very evident by examination of badly nourished children who have been bitten by insects such as midges, harvest bugs, or even fleas, at the end of the summer; many of the children are ill from the bites and often show evidence of endocarditis soon after.

**VICARIOUS MENSTRUATION.**

DR. S. WAND (Birmingham) writes: Dr. Chapman's note (June 23rd, p. 1065) regarding vicarious menstruation prompts me to mention a case I had some time ago. The patient, a girl of 17, had frequent and fairly profuse haemorrhages from her respiratory tract. They were more marked at or about her periods. I had her examined by physicians, laryngologists, and radiologists, but nothing was found. I tried a good many drugs and found that calcium lactate and thyroid combined prevented the haemorrhages for a few months. Later (two years ago) she became pregnant, and she has had no recurrence.

**MEDICAL GOLF.**

THE summer meeting of the Medical Golfing Society was held on June 19th at Walton Heath. All competitors were again the guests of Lord Riddell. The weather was fine and the course in excellent condition. The results of the competitions were as follows:

Lancet Challenge Cup.—T. A. Torrance, 3 up.	
Henry Morris Challenge Cup.—T. A. Torrance, H. T. P. Kolesar, H. Chapple.	
Molson Rev.	
Class 1.—1	Kolesar, tied
at 1 up. Be.	Jagger, H. D.
Gillies, tied at 2 up.	

**VACANCIES.**

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 46, 47, and 48 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenancies at pages 44 and 45.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 288.

## THE BRITISH MEDICAL ASSOCIATION AND COLLECTIVE INVESTIGATION.

### PART II.—A NEW VENTURE.\*

IN July last the Representative Body of the British Medical Association approved at the Edinburgh meeting a scheme of collective investigation to be carried out by the Association. The preliminary work upon the scheme was done by a special subcommittee composed of representatives of the Science Committee and the Insurance Acts Committee. Under the chairmanship of Dr. C. E. Douglas this subcommittee examined the records of similar investigations conducted by the Association in the past, the nature of the growing demand for a fresh attempt to find in the collective experience of the profession the answers to questions which daily confront the individual practitioner, and the resources available for the conduct of the proposed inquiries. The general object in view was found to be identical with that set before the Association by the special committee appointed to consider the question in 1880; the difficulties inherent in its pursuit are essentially similar to those encountered in the course of the experiment then made; but the resources available for the work are now incomparably greater than they were when the total membership of the Association did not far exceed 8,000, and the Divisional machinery which to-day gives a ready means of access to the individual member had yet to be devised. Under the scheme adopted as a result of this preliminary survey it was decided to initiate two inquiries forthwith—one into the treatment of varicose ulceration, and the other into the after-effects of gastro-enterostomy. The scheme as finally elaborated has the cordial support of the Minister of Health, expressed in a letter to the President of the Association dated November 7th, 1927, as follows:

DEAR SIR ROBERT PHILIP,

I learn with much interest that the British Medical Association, after consultation with officers of my Department, is about to institute a collective investigation into certain highly important problems of disease. The intention, as I understand it, is to secure the co-operation of a large number of medical practitioners up and down the country in a scheme of team work on an extensive scale, and so bring together the results of many varying kinds of experience. I need hardly say that this endeavour, which promises to throw light on some problems of disease that press urgently for solution, has my warmest sympathy, and I hope it will be brought to a successful issue.

Yours sincerely,  
N. CHAMBERLAIN.

\* Part I, Past Experience, was printed in the SUPPLEMENT for December 31st, 1927, page 245.

The method of approach has been carefully adjusted to the particular problems chosen for inquiry. In the case of varicose ulceration the object is to obtain a general consensus of opinion as to the most effective method of treatment. Every Division of the Association has been asked in the first instance to obtain the names of as many members as possible who will undertake to share in the investigation. The names of all those willing to co-operate will then be communicated to the Head Office by the honorary secretaries of the Divisions, and the remainder of the work will be done by the individual, the records being passed to the Head Office, where expert assistance will be available for their collation and evaluation. A memorandum explaining the object and scope of the inquiry will be sent to all those who show an interest in the subject, together with a set of questions to be answered in respect of every case recorded, and a request for general observations and conclusions based on individual experience in treatment of the condition. The memorandum and questions are printed in full below. In the case of gastro-enterostomy the object is to obtain a sufficient number of reliable histories to establish the relative values of the short-circuiting operations when performed for ulcerous, cancerous, or other conditions of the stomach or duodenum. In this problem the starting point is the surgeon's record of the exact nature of the operative procedure undertaken, and accordingly the memorandum and questions have been issued in the first instance to the surgeons of every hospital of more than one hundred beds throughout the country. Where the after-history of the cases has been followed up by the surgeon himself, he or the surgical registrar authorized by him to record particulars of his cases will be able to complete the full record. Where this cannot be done an attempt will be made to secure from the practitioner into whose care each patient has passed the particulars of the after-history of the case. The inquiry is limited to cases operated upon during the period 1920-24 inclusive. The memorandum and questions are printed in full below.

It is not intended to limit the inquiry to the cases returned by those to whom the memorandum has, as a matter of practical convenience, been addressed in the first instance, and it is hoped that any surgeon who is willing to co-operate in the work will apply to the Head Office for the necessary forms without delay, whether he has or has not received the personal request for particulars.

## INQUIRY INTO THE TREATMENT OF VARICOSE ULCERATION.

### MEMORANDUM.

Varicose ulceration is a common experience in medical practice, and every general practitioner is frequently called upon to treat it. It is accompanied by much pain and discomfort, and is responsible for a large amount of disability, especially among women. Its treatment is tedious unlike to practitioner and patient; the results are often disappointing, and relapses are common. It is a disease mainly within the province of the general practitioner, for it is he who sees the cases from beginning to end, and it is with him that the provision of treatment rests.

The treatment of varicose ulceration therefore appears to be peculiarly suitable for a collective investigation and record by general practitioners, and the collection and co-ordination of their experience would afford a valuable contribution to clinical knowledge. At present there are many methods and many claims. By a comparison of results it may reasonably be hoped that the most successful methods will be secured.

It is to this end that the accompanying questions have been arranged and are now submitted for your co-operation. The questions provide for the record of an individual case, and any number of cases may be reported. In addition, you are invited to record the conclusions that you have reached from your general experience of the treatment of varicose ulceration.

### QUESTIONS.

1. Patient (name or symbol).
2. Sex.
3. Age.
4. Occupation (precise nature).
5. Is patient insured under National Health Insurance Acts?
6. Has ulceration caused inability to work? Give approximate period.
7. At what age did ulceration first occur?
8. Indicate on the diagram on back page the position of the ulcerated surface and its approximate size before treatment commenced.
9. Has the course of ulceration been—(i) continuous, (ii) healing with relapses?
10. Suggested cause of ulcer.
11. What treatment gave the best results in this case?—namely: (i) Local—(a) bandaging, strapping, etc.; (b) nature and strength of medicaments used. (ii) Internal. (iii) Postural. (iv) Operative (give precise nature). (v) Treatment by injection.
12. For what period, if any, was rest in bed with leg raised adopted; or was treatment ambulatory throughout?
13. By whom was the ulcer usually dressed?
14. If ulcer has at any time been completely healed, were any measures adopted to prevent it breaking down again? If so, what?
15. Condition after (period of treatment).

### GENERAL OBSERVATIONS.

- (1) Please indicate from your experience what conclusions you have arrived at on (i) the preventive, (ii) the curative treatment of varicose ulceration.
- (2) Have you found benefit result from administration of calcium salts, or other internal treatment?

## INQUIRY INTO THE AFTER-HISTORY OF GASTRO-ENTEROSTOMY.

### MEMORANDUM.

It is desirable to obtain information as to the after-history of those who have undergone the operation of gastro-enterostomy during the period 1920-24 inclusive, and many general practitioners are doubtless in a position to supply this information. Surgeons regret that in many instances they are unaware of the history of patients after these have left the hospital, and if reliable information of this order could be obtained it would serve to establish the relative value of the short-circuiting operations when performed for ulcerous, cancerous, or other conditions of the stomach or duodenum.

The accompanying questions provide for an individual case, and any number of cases may be reported.

The questions are divided into two sections. Section A deals with the operative and immediate post-operative history; Section B with after-history—that is, after the patient has ceased to be an in-patient at the hospital. It is recognized that, generally speaking, Section A only of the form will be completed by or on behalf of the surgeon. Where, however, the surgeon is in possession of information relative to after-history, it is requested that he will also arrange for the completion of Section B of the form. Where Section B is not so completed it is desirable to obtain the name and address of the practitioner into whose care the patient passed after leaving hospital. The individual case will then be followed up by the Association through this practitioner.

### QUESTIONS.

#### Section A: Operative History.

1. Patient's name and if possible address.
2. Occupation.
3. Sex.
4. Age.
5. Date of operation.
6. What type of operation was performed (e.g., gastro-enterostomy anterior or posterior)?
7. Briefly, what condition was found (e.g., site and size of ulcer or growth)?
8. Reason why the operation was performed (e.g., for relief of pain, bleeding, vomiting).
9. What was the condition of patient after operation?
10. Did a test meal or an x-ray examination show any change?
11. Name and address of practitioner into whose care patient passed (if patient died in hospital please say so). (*This information is only desired to enable the case to be followed up where the surgeon is unable to supply information relative to after-history. If the surgeon is in possession of this information, it is requested that he will also complete Section B.*)

#### Section B: After-History.

12. Has the patient suffered from pain or other discomfort after food? if so, give particulars.
13. Has patient suffered from diarrhoea or constipation?
14. Is patient able to enjoy every kind of food? If not, what sort of food is avoided?
15. How long was it after operation before patient returned to work?
16. Has patient been able to do full work since then? If not, what has prevented patient from working?
17. Has patient gained or lost weight?
18. Has there been a general improvement or impairment of health and well-being since operation?
19. Mention any subsequent treatment found necessary.
20. If case has terminated fatally give: (a) date of death, (b) cause of death.

The Medical Secretary will be glad to answer any questions and give full information in regard to both inquiries. All who are interested in either subject are asked to apply to him at the Head Office of the Association, Tavistock Square, W.C.1, for the necessary forms and instructions.

## British Medical Association.

### CURRENT NOTES.

#### The Nursing Homes (Registration) Act.

The Nursing Homes (Registration) Bill was read a third time in the House of Commons and was agreed to without a division. Almost at the last moment an amendment was put down to exclude Christian Science homes from the scope of the bill. The matter was brought before the Council of the British Medical Association as one of urgency, and it was unanimously agreed to oppose the clause, even if such a step led to the wrecking of the measure. Steps were at once taken to oppose the clause, as it was understood that if there was any objection to the bill it would not come up for discussion, being a private member's bill. A strong protest was sent to the Minister of Health personally, and the decision of the Council was made known to the medical members of Parliament. During the discussion on the bill the argument was adduced by the Minister that if these homes came within the scope of the bill they would be obliged to have trained nurses on their staffs and qualified doctors in attendance, a thing which in the circumstances was absurd; and that the only alternatives were either to close them down—an act which would be regarded as religious persecution—or to make it plain that these institutions were not nursing homes. On the understanding that the amendment would be altered "in another place" to provide that these institutions should be described as "Christian Science houses" and not homes, the House agreed to the amendment, as it was thought that this designation would prevent persons going into them under the impression that they were ordinary nursing homes. A perusal of the debate (reported under Medical Notes in Parliament in the last two issues of the JOURNAL) shows that several speakers were not altogether satisfied, and it is manifest from the report of the proceedings in the House of Lords that, as is

not uncommon at this stage of the session, the bill was handled with a haste which might almost be described as indecent. The bill received the Royal Assent on December 22nd, 1927.

#### Civil Servants and Membership of the B.M.A.

There has been some doubt as to whether the Civil Service (Approved Associations) Regulations, formulated in accordance with the Trade Disputes and Trade Unions Act, 1927, would prevent an established civil servant from becoming or remaining a member of the British Medical Association. The Medical Secretary is given to understand that there is nothing in these regulations to prevent an established civil servant from belonging to the Association.

#### The Hempton Prize.

Mr. W. E. Hempton has placed at the disposal of the Council, upon his retirement in March next from the post held by him for thirty years of Solicitor of the Association, and as a mark of esteem for the Association and appreciation of his happy relations therewith, a sum of twenty-five guineas, to be awarded as a prize for the best essay or treatise on some phase or branch of public health. The subject approved by the Council for the prize is "A study of personal experiences in the inspection and treatment of school children under the auspices of any elementary education authority." The following conditions govern the award of the prize:

1. Only members of the Association are eligible to compete.
2. Studies must be sent to the Medical Secretary, British Medical Association House, London, W.C.1, not later than December 31st, 1928, and the prize will be awarded at the Annual General Meeting of the Association at Manchester in 1929.
3. No study that has been published in the medical press or elsewhere will be considered eligible.
4. If any question arises as to the eligibility of the candidate or the admissibility of his study, the decision of the Council on any such point shall be final.
5. Each study must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.
6. Inquiries relative to the prize should be addressed to the Medical Secretary.

#### Subscriptions for 1928.

Members of the British Medical Association are reminded that subscriptions fall due on January 1st in each year, and that if each member on receiving an application for his or her subscription from the Head Office will send the amount to the Financial Secretary without delay the work of the office will be very considerably lightened. Members are also reminded of the claims of charity. The amounts at the disposal of those who administer medical benevolence are altogether insufficient to deal adequately with the cases needing help, and the British Medical Association Charities Fund was formed in order to assist. Contributions are urgently needed, and all members are asked to add to their next payment a sum for the credit of that Fund.

### Association Notices.

#### BRANCH AND DIVISION MEETINGS TO BE HELD.

**BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.**—A clinical and pathological meeting of the Nuneaton and Tamworth Division, arranged by Dr. Pracy, will be held at the Nuneaton General Hospital on Wednesday, January 11th.

**BORDER COUNTIES BRANCH: ENGLISH DIVISION.**—A meeting of the English Division will be held at Maryport on Friday, January 27th. Dr. J. N. Douglas Smith will read a paper on the early treatment of puerperal sepsis.

**GLASGOW AND WEST OF SCOTLAND BRANCH: LANARKSHIRE DIVISION.**—A meeting of the Lanarkshire Division will be held at St. Enoch Station Hotel on Wednesday, January 11th, at 3.30 p.m. Dr. Douglas Guthrie (Edinburgh) will read a paper on the septic tonsil and discharging ear, with lantern illustrations.

**ESSEX BRANCH: SOUTH ESSEX DIVISION.**—A meeting of the South Essex Division will be held on Tuesday, January 10th, when Mr. E. C. Hughes will give an address on surgical mistakes.

**LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.**—A clinical meeting of the Hyde Division will be held in the Maternity and Child Welfare Centre, Hyde, on Thursday, January 26th, at 8.30 p.m.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—The next clinical meeting of the City Division will be held on Friday, January 13th, at 4.15 p.m., when Dr. Norman Hill will show cases. Tea.

**METROPOLITAN COUNTIES BRANCH: FINCHLEY DIVISION.**—A meeting of the Finchley Division will be held at the Finchley Memorial Hospital on Tuesday, January 10th, at 8.45 p.m. Mr. W. S. Porritt will read a paper.

**METROPOLITAN COUNTIES BRANCH: HAMPSHIRE DIVISION.**—A meeting of the Hampshire Division will be held at the Hampshire General Hospital on Thursday, January 12th, at 8.30 p.m. Dr. T. Izod Bennett will read a paper on the treatment of gastric ulcer.

**METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.**—A clinical evening arranged by the Lewisham Division will be held at the South-Eastern Children's Hospital, Sydenham, on Tuesday, January 17th.

**METROPOLITAN COUNTIES BRANCH: MARYLEBONE DIVISION.**—By the kind invitation of Mr. H. S. Wellcome a meeting will be held at the Wellcome Historical Museum, 51A, Wigmore Street, W.1, on Wednesday, January 18th, at 8.15 p.m., when the conservator, Mr. Malcolm, will demonstrate in the various sections of the museum. Ladies are invited, and Mr. Wellcome has kindly offered to provide hospitality. Members proposing to bring guests are asked to notify Dr. W. Griffith (honorary secretary), 1, Harley Street, W.1.

**METROPOLITAN COUNTIES BRANCH: NORTH MIDDLESEX DIVISION.**—At the meeting of the North Middlesex Division to be held on Wednesday, January 25th, Mr. T. H. C. Benians will read a paper on local immunization and antiviral therapy.

**METROPOLITAN COUNTIES BRANCH: ST. PANCRAS DIVISION.**—A meeting of the St. Pancras Division will be held at the British Medical Association House, Tavistock Square, W.C.1, on Tuesday, January 10th, at 9 p.m. Sir Squire Sprigge will read a paper entitled "The middle years."

**METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.**—A meeting of the Willesden Division will be held at the Willesden General Hospital, Harlesden Road, N.W., on Wednesday, January 18th, at 9 p.m. Dr. Christine Murrell will discuss the question of nursing homes for middle-class patients.

**MIDLAND BRANCH: CHESTERFIELD DIVISION.**—A meeting of the Chesterfield Division will be held at the Maternity Hospital, Chesterfield, on Friday, January 13th, at 8.15 p.m. Mr. W. W. King will read a paper on dysmenorrhoea—as a cause and a symptom.

**MIDLAND BRANCH: HOLLAND DIVISION.**—A meeting of the Holland Division will be held at Spalding-to-day (Friday, January 6th), at 3 p.m. Sir Humphry Rolleston, Bt., Regius Professor of Physic in the University of Cambridge, will give a British Medical Association Lecture on the medical aspects of idiosyncrasies.

**NORTH OF ENGLAND BRANCH: BISHOP AUCLAND DIVISION.**—A meeting of the Bishop Auckland Division will be held at the Cottage Hospital, Bishop Auckland, on Friday, January 27th, at 8 p.m. Dr. J. C. Spence will give a lecture on medical emergencies in children.

**NORTH OF ENGLAND BRANCH: TYNESIDE DIVISION.**—The Tyneside Division has arranged to hold a dinner on January 13th. Sir Robert Bolam has promised to attend, and the member of Parliament for Tyneside, Major West Russell, has been invited.

**OXFORD AND READING BRANCH: OXFORD DIVISION.**—A meeting of the Oxford Division will be held in the Radcliffe Infirmary on Wednesday, January 25th, at 2.30 p.m. Dr. T. Izod Bennett will lecture on recent advances in pernicious anaemia.

**SOUTHERN BRANCH: JERSEY DIVISION.**—A meeting of the Jersey Division will be held at the General Hospital on Thursday, January 19th, at 8.30 p.m. Dr. H. W. Marett Tims will read a paper on heredity in relation to social problems.

**SOUTHERN BRANCH: PORTSMOUTH DIVISION.**—The annual dance arranged by the Portsmouth Division in aid of medical charities will be held at the Savoy Café on Tuesday, January 10th. The next meeting of the Portsmouth Division will be held at the Queen's Hotel, Portsmouth, on Thursday, January 12th, at 9.30 p.m., preceded by a supper at 9 o'clock (cost 3s. 6d., including gratuities). Mr. E. Mapother, medical superintendent, Mandsley Hospital, will give an address on the possible co-operation of the profession in the treatment of mental disorders. Members who desire to take part in the Treasurer's Cup golf competition are asked to send their names to Dr. Mearns Fraser, 32, St. Ronan's Road, Southsea. Members intending to be present at the supper are requested to notify the honorary secretary.

**SOUTH-WALES BRANCH: SOUTH-WEST WALES DIVISION.**—Dr. Frederick W. Price will give a British Medical Association Lecture at 3 p.m. on Wednesday, January 11th, at the Carmarthenshire Infirmary, Carmarthen, on some recent advances in the diagnosis, prognosis, and treatment of heart disease. Tea will be provided at the Infirmary.

**SOUTH-WESTERN BRANCH.**—An intermediate meeting of the South-Western Branch will be held in the Library of the Royal Devon and Exeter Hospital, on Thursday, January 19th. Members desiring to bring forward cases, notes, papers, specimens, or notices of motion are asked to notify the honorary secretary, Dr. P. D. Warburton, 15, Southernhay East, Exeter, in order that they may be placed on the agenda paper.

**SUFFOLK BRANCH: SOUTH SUFFOLK DIVISION.**—The annual meeting of the South Suffolk Division will be held at the Crown and Anchor Hotel, Ipswich, to-day (Friday, January 6th), at 3.30 p.m. Agenda: Representative and flag funds; annual report and balance sheet; election of officers for 1928; public education in health (Dr. A. M. N. Pringle, M.O.H., will explain proposals); address by Dr. J. F. Walker on medical charities. As this is the most important Divisional meeting of the year it is hoped that every member will make a special effort to attend.

**SURREY BRANCH: CROYDON DIVISION.**—A meeting of the Croydon Division will be held at the Croydon General Hospital on Wednesday, January 11th, when Dr. G. Lewin will give a lantern demonstration on Bazin's disease. The meeting will be preceded by tea at 4 p.m.

**WEST SOMERSET BRANCH.**—A clinical meeting of the West Somerset Branch will be held at the Taunton and Somerset Hospital on Tuesday, January 24th, at 3.30 p.m. A paper open to discussion will be read by Dr. W. H. Maidlow (Ilminster) entitled "A to Z. Subjects of interest to the general practitioner." Tea will be served at 4.30 p.m.

**YORKSHIRE BRANCH: DEWSBURY DIVISION.**—A meeting of the Dewsbury Division will be held at the Batley Hospital on Friday, January 13th. Mr. L. R. Braithwaite (Leeds) will read a paper on chronic pains in the right iliac fossa.

**YORKSHIRE BRANCH: WAKEFIELD, PONTEFRAC, AND CASTLEFORD DIVISION.**—A meeting of the Wakefield, Pontefract, and Castleford Division will be held at the Great Bull Restaurant, Westgate, Wakefield, on Thursday, January 12th. Dr. G. B. Hillman will give a lecture on the insurance practitioner and some of his relationships. Supper (2s. 6d.), at 7.45 p.m., will precede the lecture.

## Meetings of Branches and Divisions.

### EDINBURGH BRANCH: EDINBURGH AND LEITH DIVISION.

#### Reception to New Graduates.

A RECEPTION was given by the Edinburgh and Leith Division on December 15th, 1927, to medical students who had recently graduated, and Mr. DAVID LEES delivered an address on medical ethics. After referring to the great traditions of the Edinburgh School of Medicine, he compared them with the historic rules of conduct associated with the name of Hippocrates. Mr. Lees then dealt with the ethics of medicine, with special reference to the conduct of general practice. He said that ethics defined what a man ought to do and he; its rules were based on a threefold conception of duty—namely, to patients, to colleagues, and to the laws of the State. Daily association with patients required the possession of a sense of duty, conduct, and character which included a decisive mind, self-control, and consideration for the views and opinions of others. Professional rivalry should be encouraged, being always in the interests of individuals and of medicine; professional jealousy, on the other hand, brought medical practice into contempt. Mr. Lees then gave an indication of the course to be adopted in the matter of transference of patients from one doctor to another. He referred to his recent visit to India, and commented on the prevailing lack of any ethical code among many of the graduates of the younger universities in the East. He believed that this resulted in harm to the profession and to patients, and detracted from the respect which should be accorded to a medical practitioner. Mr. Lees referred briefly to the work of the General Medical Council, and urged the members of his audience to make themselves familiar with all their statutory obligations.

### LANCASHIRE AND CHESHIRE BRANCH: ROCHDALE DIVISION.

A MEETING of the Rochdale Division was held at the Lyceum, Rochdale, on December 14th, 1927, when Dr. E. H. Cox, D.S.O., the chairman, presided.

A resolution of condolence with the widow of the late Dr. James Melvin, sen., was passed, all the members standing in silence.

Dr. L. KILNOR was elected secretary in place of the late Dr. James Melvin, sen.

Dr. DANIEL DOUGAL, lecturer in obstetrics and gynaecology at the University of Manchester, read a paper on "Haemorrhage about the menopause: its investigation and treatment." The address was followed with great interest by the meeting, and, after discussion, Dr. Dougal was heartily thanked for his lecture.

### METROPOLITAN COUNTIES BRANCH: CITY DIVISION.

#### Annual Dinner.

THE annual dinner of the City Division was held at the Trocadero Restaurant on December 1st, 1927, when Dr. PHILIP HAMILL was in the chair. Among the guests of the Division were Dr. W. Langdon Brown, Professor Hugh Maclean, Dr. N. G. Horner (the Assistant Editor of the *BRITISH MEDICAL JOURNAL*), Dr. Anthony Feiling, Dr. R. Brontë, Mr. Capps, and Dr. Lucey. An excellent dinner was enjoyed by the eighty members and guests present, and the latter part of the evening was pleasantly passed enjoying the toasts and musical entertainment.

The toast of "The British Medical Association" was admirably proposed by Professor HUGH MACLEAN, and replied to neatly and shortly by Dr. HORNER. Dr. KENNEL proposed the toast of "The Guests," which was replied to by Dr. Langdon Brown. The toast of "The Chairman" was proposed by Dr. HAROLD LATHAM, and acknowledged by Dr. HAMILL, and many compliments were paid to the honorary secretary, Dr. W. E. A. Worley, for his services to the Division.

The musical entertainment was provided by Mrs. Westerman, the wife of a past chairman, and Mr. Sterndale Bennett, who gave sketches at the piano. The Division owes a deep debt of gratitude to Mrs. Westerman for her kindness in enabling the Division to enjoy singing of a character not obtainable at smoking concerts.

### METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.

A MEETING of the Lewisham Division was held at the Town Hall, Cntford, on December 20th, 1927, when Dr. W. E. HALLINAN occupied the chair.

Dr. ROSE JONNAN, tuberculosis officer for Lewisham, read a paper on the differential diagnosis of pulmonary tuberculosis. She said that in Lewisham, with its area of 7,015 acres and population of 187,800, the death rate was 10, and the deaths from tuberculosis in 1920 numbered 162, of which 135 were due to tuberculosis of the lungs. She showed charts illustrating the steady fall of the tuberculous death rate in this borough and in the county generally. Important diagnostic points were the personal and family history and the general appearance. In the physical examination the patient should be stripped to the waist and palpation performed with the flat hand. During auscultation the patient must breathe through the month. Children were much more difficult to diagnose than adults, and it was hard to detect tuberculosis when the chest was full of adventitious sounds, as in bronchial asthma. The bronchitic chest was usually symmetrical, and in cardiac cases sounds were heard at the bases. Bleeding seldom came from the throat and was then always small in amount. Young adults with haemorrhage often did very well, since they had few other symptoms.

Dr. E. OFFENHEIM described Verne's test, as applied to the diagnosis of tuberculosis, and said that there were three known fallacies—namely, the presence of early chancre, advanced cancerous cachexia, and neutrolobar pneumonia.

Dr. F. H. EVANS, G. JONES, BEATTIE, and HALLINAN joined in the discussion, and a vote of thanks was passed to the lecturer.

### METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.

A MEETING of the Willesden Division was held at the Willesden General Hospital on December 21st, 1927, when Dr. N. R. BEATTIE, assistant medical officer of health for Willesden, read a paper on public education in health.

Dr. Beattie alluded to the favourable statistics of puerperal morbidity in the Willesden area in the previous year, and he noted this as a striking proof of the value to the community of the health services. He pleaded for the greater co-ordination and centralization of the many official and unofficial health services now operating. He envisaged all medical services under the control of the State as the ideal towards which the present services were inevitably, if slowly, evolving. Dr. Beattie criticized the present teaching of hygiene in the medical schools in view of the elementary character of the instruction and the uninspired manner in which this branch of medicine was presented to the student. Dr. Beattie offered several suggestions for educating the lay public. The teaching of hygiene in schools should be given a prominent place in the curriculum, and should be efficient; the present practice was negative in both these respects. Secondly, the Churches should be explored regarding the possibility of their facilitating the propagation of knowledge of hygiene: co-operation between the priest and the doctor in a joint effort for the dissemination of this knowledge was very desirable. The utilization of the press for the same purpose, if intelligent and on organized lines, could become a most effective channel for instilling into the public mind the laws of health.

A very interesting discussion followed the reading of this paper, and many of the obstacles to be overcome in forwarding a scheme of health education were considered. Dr. Beattie was recorded a hearty vote of thanks, and the question was referred to the Executive Committee.

Dr. W. LOCK presented the report of the Dinner Committee, and was warmly thanked for making the arrangements for a very successful evening.

### SOUTH WALES AND MONMOUTHSHIRE BRANCH: CARDIFF DIVISION.

A MEETING of the Cardiff Division was held on December 15th, 1927, when Professor W. E. DIXON, M.D., F.R.S., Reader in Pharmacology in the University of Cambridge, delivered a British Medical Association Lecture on the trend of thought in modern therapy, which was attended by about a hundred members of the Division. Professor Dixon was in his very best form, and spoke for fully an hour and a quarter. He dealt with many aspects of modern therapy, and the lecture was thoroughly enjoyed and much appreciated by the audience. At its conclusion Professor Dixon was entertained by the Division to supper at the Park Hotel.

### ULSTER BRANCH: FERMANAGH DIVISION.

As already briefly reported in our issue of December 24th, 1927 (p. 1203), Dr. Leonard Kidd invited, on December 15th, the medical profession to the 10th Donegal dinner in Enniskillen for the 10th anniversary of the Fermanagh Division of the British Medical Association. The meeting Dr. Hennessy (the Irish Medical Secretary). A large and representative company was present, and enjoyed Dr. Kidd's hospitality. The toasts of "The King" and "The British Medical Association" having been duly honoured, Dr. HENNESSY gave a very interesting and instructive account of the working of the British Medical Association and the great part it played in the medico-political, scientific, and economic life of the profession. They were all aware of the benefits derived from membership of such a powerful Association, and it was unnecessary for him to dwell unduly upon this point. He instanced the financial improvement in the salaries of many medical men brought about through the instrumentality of the British Medical

Association. The BRITISH MEDICAL JOURNAL, which members received weekly, was one of the leading medical journals of the world, and would always keep members abreast of current clinical, scientific, and medico-political thought. He was delighted to have invited himself of Dr. Kidd's hospitality and to be amongst them in Fermanagh that evening. Dr. Kidd and he had been very old friends—their common desire (though perhaps differing slightly in their methods) had always been the promotion of the best interests of the profession. He sincerely hoped that the Division would be established on a sure footing in county Fermanagh, and he wished Dr. Kidd and his fellow workers every success in their undertaking.

The following officers were then elected:

Chairman, Dr. L. Kidd. Vice-Chairman, Dr. T. C. Taylor. Secretary-Treasurer, Dr. J. Maguire.

Dr. Kidd subsequently referred to the report of the Poor Law Commission (Northern Ireland). He deplored the fact that there was no mention of a Minister of Health, and criticized various other defects in the report. He drew attention also to the form of medical certificate required by sick jurors at present in Northern Ireland—whereon the precise cause of the illness had to be stated. Dr. Kidd thought that the form should be altered, and advised their representative to bring up the matter at the Branch Council.

Dr. T. A. SMYTH said that the educational committees (regional) now required medical certificates for children when absent from school through illness. In the case of dispensary patients and those unable to pay, the committee had made no attempt to pay for medical certificates. Dr. Smyth had invariably refused certificates in these cases, and would still continue to refuse them (unless the committee made some arrangement with the doctors about payment). This was an important matter, and should be raised in the proper quarter.

Heartly votes of thanks were accorded Dr. Hennessy for his interesting address, and to Dr. Kidd for his kindness and hospitality. The general consensus of opinion was that this had been one of the most enjoyable and profitable evenings ever spent by the profession in Fermanagh.

## National Insurance.

### THE PROVISION OF DENTAL BENEFIT.

THERE can be little doubt that if Parliament were now establishing the national health insurance system with the advantage of present experience, the position of dental benefit and of what are now called additional treatment benefits would be fundamentally altered. There can be no justification in any national health scheme for making dental treatment and certain forms of special medical treatment available only for some, and not for all, insured persons, irrespective of their needs and of the fact that all alike pay the same insurance premium. There is really no excuse for the continuance of this state of things when once its existence has been disclosed as the result of the societies' valuations; and the only explanations are the congestion and inertia of Parliament and the obstinate tenacity with which the societies have clung to the whole of their segregated funds and refused a partial national pooling thereof—a refusal which, it seems, cannot be upset on legal grounds, but can have not the slightest justification on any other ground whatever. So manifestly unjust is the position now seen to be that the continued obstinacy of the societies is beginning to undermine their whole position in public opinion; and the superior foresight of that small minority of approved society officials who have been favourable towards the partial pooling of funds recommended by the Royal Commission for these purposes will probably become evident before very long.

Though they are alike in their partial and haphazard availability, dental benefit and the additional treatment benefits differ from one another as to their provision and administration. Dental benefit is defined as "the payment of the whole or any part of the cost of dental treatment," and the additional treatment benefits are described in sanctioned schemes as "the payment of the whole or part of the cost of" certain forms of medical treatment or ancillary services. In spite of this similarity of definition, approved societies can have nothing to do with the provision and administration of forms of medical treatment, as this is held to be "of the nature of medical benefit," and therefore administrable only by Insurance Committees and not by approved societies; whereas dental benefit being in a separate category in the schedule of additional benefits,

the provision and administration of dental treatment may legally be undertaken by approved societies themselves. This distinction between the provision of the cost of some forms of medical treatment and the provision of the treatment itself is obviously very thin, and it is more than likely that if the profession had been in a position boldly to challenge this departmental distinction at the outset in the law courts, and to carry the case to the House of Lords, the result would have justified the action. It is a question whether it is now too late to make such an action worth while.

As things are, however, the dental profession is in a different position from the medical profession in relation to the approved societies. In the latter case, direct negotiations with regard to terms and conditions of service have always been refused; in the former case such negotiations were clearly a necessity if there were to be any degree of uniformity of benefit or collective influence on the part of dentists. Such negotiations took place last year under the auspices of the Ministry of Health and the Scottish Board of Health by means of a joint committee composed of fourteen dental representatives and a like number of representatives of the societies. Fortunately for the dentists, certain principles and precedents have been established by the Medical Benefit Regulations, which it was agreed to follow; some important points had thus been safeguarded by the previous action of the medical profession. The result of the work of the joint committee is a scheme which, though not binding upon any particular approved society, and always limited by the amount of money disposable in any year for the purpose of dental benefit, has been accepted by societies covering about 95 per cent. of the insured persons concerned. Particulars as to what exactly is included under the term "dental treatment," as to the procedure to be followed when such treatment is claimed, and as to the terms and conditions of service of dentists in connexion therewith, have been communicated to approved societies and to dentists from time to time by means of circulars and professional journals, and certain aspects of the scheme were commented upon in our columns (SUPPLEMENT, October 9th, 1926, p. 161) some months ago. There is still, however, a good deal of ignorance or doubt in connexion with the scheme, and the joint committee has just issued a "Dental Benefit Handbook" (His Majesty's Stationery Office, price 3d.), setting out in convenient form such details and explanations as seem necessary, and giving, in addition, a summary of the principal decisions of the interpretation committee and certain selected decisions of the investigation committee, such committees being in the nature of courts of appeal.

The medical profession is no party to these negotiations or arrangements in any sense whatever. Its interest in them is indirect, and may be said to be of a threefold character. First, practitioners may wish to know sufficient of the scheme to help their patients to obtain any dental treatment to which they are entitled. Secondly, the provisions with regard to anaesthetics in connexion with dental benefit may have some bearing on medical fees for the administration of such anaesthetics. Thirdly, it is possible that certain features of the scheme should be noted, as warnings or otherwise, when any extensions of the insurance medical service come to be discussed in more detail.

Not all societies provide dental benefit. Even when a society does provide it a member does not normally become entitled to such benefit till the beginning of January in the fifth year after that in which he last joined the society. The only obligation of an insurance practitioner is that, if he has advised his patient to obtain dental treatment, if the patient's society has notified the practitioner that the patient is entitled to such treatment, and if the patient is already under certification, he must

enter on the next regular certificate issued to the patient a statement that dental treatment is recommended. But most practitioners will be quite willing, even without charging a fee, to help their patients in this regard without any narrow insistence on this limited obligation. The benefit ordinarily consists of payment by the society of the whole cost of operative treatment and not less than half the cost of dentures; but owing to lack of funds set aside for this purpose certain societies have been authorized to pay only 75 per cent. of the cost of operative treatment; and some have been obliged temporarily to suspend the benefit altogether. This treatment may be obtained by the patient from any registered dentist who is working under the scheme. In order to obtain a grant the member must ordinarily, before any treatment is begun, have submitted the dentist's estimate to the society and have obtained the society's authorization.

The scale of charges agreed upon is no concern of the medical profession. There are some indications that at the moment it is more satisfactory to the dentists than to the societies. The scale of charges for anaesthetics is, however, of some interest. It is not binding on any medical man, and has, in fact, been repudiated entirely by the British Medical Association. It contains two provisions which are of an extraordinary, not to say ludicrous, character. One of these is that where there are extractions from both jaws the anaesthetic fee is to be higher than if the extractions are from one jaw only. The other is that only one administration fee is to be charged to each patient, even if that patient requires more than one administration. No explanation of these remarkable provisions has, so far as we know, ever been vouchsafed. The actual fees prescribed are: (1) simple administration of nitrous oxide or similar anaesthetic, one jaw 7s. 6d., both jaws 10s.; (2) prolonged anaesthesia where not less than twelve teeth are extracted at one operation, £1 1s. These are the fees on which the dentist must estimate, and which will be paid to him if the society accepts his estimate. If he employs a medical practitioner as anaesthetist it is to be presumed that he will not be very willing to pay the anaesthetist larger fees than he will himself be allowed, and he is not allowed to charge his patient any larger fees than these. If, however, the patient himself asks to have his own medical attendant as anaesthetist, and the fee is in excess of those mentioned, the dentist may arrange this with the doctor and charge the excess to the patient.\* The choice of an anaesthetist rests with the dentist. A knowledge of the conditions set out above may be useful to medical anaesthetists arranging their fees with the dentist. In all cases of prolonged anaesthesia the anaesthetist must be "either a medical practitioner or a dentist (other than the dentist performing the extractions) skilled in the administration of a suitable general anaesthetic and included in a list to be approved by the Dental Benefit Joint Committee." As we previously pointed out, the obvious ambiguity of this provision would be completely avoided by the insertion of a comma after the words "medical

practitioner." For some reason the Joint Committee has preferred not to insert the comma, but to explain elsewhere that the proviso applies only to a dentist and not to medical practitioner. Even so, the explanation is expressed incorrectly. The handbook states (p. 15) "any registered medical practitioner, therefore, is entitled to receive a fee under Item 5 (b) (ii) irrespective of the inclusion of his name in the panel." The medical practitioner, cannot be too clearly understood, has no rights or duties under this scheme at all. What is meant is that the dentist has the right to employ a medical practitioner as anaesthetist and to receive the prescribed fee in respect of administration. The difference is not negligible.

There are two points worth noting in connexion with possible developments of the medical insurance service. One is an important difference of function between the regional dental officer and the regional medical officer. The former may be (it seems, usually is) required to judge of the propriety of the dental treatment which his professional colleague proposes to give his patient, and the quality and success of such professional work after has been given. This seems, on the face of it, a highly undesirable state of affairs, and if it must be accepted, the best dentists as a regrettable necessity with regard to dental work and in the present conditions of the dental profession, it cannot be too emphatically stated that inspectorial functions analogous to these would never be tolerated for a moment by the medical profession. The second point is the statement of the joint committee with regard to dental clinics. The committee does not express any definite opinion on the question of the general institution of dental clinics, but "recommends that an experimental dental clinic be set up in a suitable area or areas, if possible under the supervision of the Minister of Health or the Scottish Board of Health," and says that "the steps necessary to give effect to this recommendation are not being taken by the committee." We made some comment on such a proposal in the JOURNAL of August 27th, 19 (p. 355).

## Correspondence.

### Ophthalmic Clinics for Insured Persons.

SIR,—The letter in the SUPPLEMENT of December 24th, 19, from Dr. Bickerton is so misleading that I feel obliged to reply to it. I do not agree with the policy of the Ophthalmic Committee of the British Medical Association; in my opinion they are making a fatal mistake in advocating clinics. Already there are signs that some societies are taking advantage of the favour shown by the British Medical Association to the club system and are actually starting clinics themselves, which as we might have been expected, entirely controlled by the societies.

It is all very well to divide societies into good and bad but it is a false division. A society formed from members of a good social position has a far lower sickness rate than one formed from members of an unhealthy trade. The surplus varies in different societies. One can afford to give its members extra benefits, whereas another finds itself with no surplus funds. Are we to label the latter a "bad" society on that account? It is no good to argue that as there is a surplus of over one hundred millions in the National Insurance Fund therefore the societies can afford to pay the fee required. The fees are paid by individual societies, and not by the nation fund.

The fault of the whole matter is that we have not consented to let certain varieties of defects of sight, mainly cases of presbyopia, go to opticians. It is ridiculous to send every patient, without any discrimination, to an ophthalmic surgeon. The Panel Conference recognized this, and voted accordingly. The dictum, "Send all cases to an ophthalmic surgeon," must be modified. As was stated to the Panel Conference by a representative of the Ministry, it is impossible to pay for the only other way of overcoming the difficulty is to treat cases of presbyopia at a lower fee than the guinea.

To compare school clinics with those that are proposed for societies is a very poor argument. School children are all under one authority, and are treated in most areas by whole-time men as a part of their duty as school medical officers. Suitable

\* This statement is in accordance with the paragraph in the body of the "Dental Benefit Handbook," page 16: "Enquiries have been received as to the proper procedure in cases of simple administration in which insured persons desire to have their own doctors, either to administer the general anaesthetic or to be present at its administration by the dentist. It has been agreed that in the first type of case the payment of the doctor's fee is a matter for arrangement between the patient and the dentist, the patient paying to the dentist the difference, if any, between the doctor's fee and the administration fee payable by the society, and the dentist then making himself responsible for the payment of the whole fee to the doctor." But see page 50, under "Summary of the principal decisions of the Interpretation Committee":

"Case No. 955. If a patient desires to employ his or her own medical attendant to administer ordinary nitrous-oxide gas, and is willing to pay the fee, is this permissible under the scale?—Decision: If the patient desires to employ his or her own anaesthetist for the ordinary administration of nitrous oxide the patient is liable and must pay the anaesthetist's fee, the dentist charging only the scale fee for the extraction." Some further explanation seems called for.

premises and apparatus are provided by the education authorities, and the children can be dealt with at certain hours in the lump. To compare the two is to suggest that the societies shall set up clinics and work on the same system, which would be disastrous.

We have got to get our living and to protect our profession from being exploited. Does the writer of the letter consider the fees suggested as suitable for clinic work to be at all satisfactory? I think they are an insult. The result of starting clinics will be to lower the whole status of ophthalmic work. How futile it is to suggest that the members should pay the difference between the clinic fee and that of an ophthalmic surgeon if they want the latter! At the present day working men are out to get everything for little or nothing. How many will pay the extra fee?

Then, in the last paragraph, the writer states: "At present those who do not like the clinic scheme need not undertake the work." This is to say that if a clinic is established in the town where I reside I am to lose all my ophthalmic work if I do not join the clinic. That is a nice brotherly position to take up, is it not? If the clinic system is adopted the societies will obtain control, put in the medical man who is willing to do the work at the cheapest rate, and the rest can go to the devil!

If hospital ophthalmic surgeons are so foolish as to do work for nothing, for which they would be paid if they went about it in the right way, it is only another example of the lack of business aptitude of medical men. Every hospital ophthalmic surgeon should put his foot down and say, "I will not treat members of societies at the hospital." If they do not do this they are acting unfairly to themselves and to other colleagues who depend partly on ophthalmic work for a living.

I trust that clinics will not be established. It is by far the best plan to stick to the guinea fee and see the patients at our own rooms, making a modified charge for simple cases, such as presbyopia, or letting them go at their own risk to an optician.

I am afraid the Ophthalmic Committee of the British Medical Association has too many ophthalmic surgeons as members to the exclusion of those who are familiar with panel work and know the conditions of general practice in connexion with the panel. There are many men who have taken up refraction work as a sideline; these should be represented.—I am, etc.,

Hastings, Dec. 27th, 1927.

ARTHUR E. LARKING.

## WILLIAMS-FREEMAN PRESENTATION FUND.

The following is the fourth list of subscriptions received in response to the letter published in our columns of October 1st, 1927 (p. 159):

Cheques should be made payable to the Williams-Freeman Presentation Fund, and addressed to Dr. D. G. Greenfield, Treasurer, c/o the Medical Secretary, British Medical Association, British Medical Association House, Tavistock Square, London, W.C.1.

## Naval and Military Appointments.

### ROYAL NAVAL MEDICAL SERVICE.

Surgeon Lieutenant Commanders F. G. Hunt to the *Tamar* for Hong-Kong Dockyard; P. H. Vey to the *Victory* for Portsmouth Dockyard; C. T. Hyatt to the *Field*.

Surgeon Lieutenants D. Duncan to the *Vernon*; J. H. Nicolson to the *Tiger*, temporary, and to the *Cornwall* on commissioning with full complement; S. G. Weldon to the *Acta*, temporary.

### ROYAL ARMY MEDICAL CORPS.

Colonels G. M. Goldsmith, C.B.E., and H. D. Packer, C.I.E., into R.A.M.C., retire on retired pay.

Colonel R. H. Lloyd, late R.A.M.C., is placed on half pay under the provisions of Articles 139 and 485, Royal Warrant for Pay and Promotion, 1926.

Lieutenant-Colonels from R.A.M.C. to be Colonels: E. McDonnell, D.S.O., vice Colonel G. M. Goldsmith, C.B.E., to retired pay; Brevet Colonel A. H. Safford, vice Colonel R. H. Lloyd to half pay; Brevet Colonel J. W. West, C.M.G., K.I.S., vice Colonel H. D. Packer, C.I.E., to retired pay.

Lieut.-Colonel A. McManis, O.B.E., having attained the age fixed for compulsory retirement, retires on retired pay.

Majors to be Lieutenant-Colonels: V. Low, D.S.O., O.B.E., vice Lieut.-Colonel E. McDonnell, D.S.O., promoted; A. N. Fraser, D.S.O., vice Lieut.-Colonel and Brevet Colonel A. H. Safford, promoted; R. H. L. Cordner, vice Lieut.-Colonel and Brevet Colonel J. W. West, C.M.G., K.I.S., promoted.

Captain G. T. Gimlette to be Major (prov.).

Temporary Lieutenant O. A. Owen-Flood (Lieutenant, Regular Army Reserve of Officers, Royal Irish Fusiliers) relinquishes his temporary commission.

### ROYAL AIR FORCE MEDICAL SERVICE.

The promotion of the following officers is announced in the Supplement to the *London Gazette* of January 2nd, containing the list of New Year Honours, etc.: Wing Commander E. C. Clements, O.B.E., to be Group Captain; Flight Lieutenant (Acting Squadron Leader) J. N. MacDonald to be Honorary Wing Commander.

Flight Lieutenants O. J. Griffiths to R.A.F. Station, Bicester; D. B. Smith to Station Headquarters and Storage Section, Andover.

### INDIAN MEDICAL SERVICE.

The services of Lieut.-Colonel G. W. Macdonachie have been placed at the disposal of the Government of Bihar and Orissa, for employment as Officiating Inspector-General of Prisons, Bihar and Orissa.

On reversion from the cadre of Agency Surgeons under the Government of India in the Foreign and Political Department, the services of Major C. J. Stocker, M.C., are placed temporarily at the disposal of the Government of the Central Provinces.

The services of Captain M. T. Khundwalla are placed temporarily at the disposal of the Government of Madras for employment in the Jail Department.

Lieut.-Colonel W. H. C. Forster to be Colonel, vice Colonel A. Fenton, retired.

Lieutenant J. H. Clapp to be Captain.

Lieut.-Colonels T. S. Norris, V.H.S., and W. F. Harvey, C.I.E., have retired from the service.

## VACANCIES.

BOURNEMOUTH: ROYAL VICTORIA AND WEST HINTS HOSPITAL.—House-Surgeon (male) for the Boscombe Branch. Salary £120 per annum.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd Street, W.C.1.—(1) Two Out-patient Officers; remuneration at the rate of £150 per annum. (2) Junior House-Surgeon; salary at the rate of £50 per annum.

CROYDON COUNTY BOROUGH.—Assistant Medical Officer of Health and Assistant School Medical Officer. Salary £600 per annum.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Honorary Gynaecologist.

EXETER: ROYAL DEVON AND EXETER HOSPITAL.—Senior House-Surgeon (male). Salary £200 per annum.

FREMAMONS HOSPITAL AND NURSING HOME, 237, Fulham Road, S.W.3.—Resident Medical Officer (male). Salary at the rate of £250 per annum.

GLASGOW ROYAL CANCER HOSPITAL.—Research Worker. Salary £800 to £1,000 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.3.—Two House-Physicians. Honorarium £50 for six months.

IPSWICH: EAST SUFFOLK AND IPSWICH HOSPITAL.—Casualty Officer (male). Salary £150 per annum, rising to £200.

KENSINGTON, FULHAM, AND CHelsea GENERAL HOSPITAL.—Honorary Dental Surgeon (male).

LEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £150 per annum.

LINCOLN: THE LAWN.—Medical Superintendent. Salary £700 per annum.

LOCHCANNON PARISH COUNCIL, Ross-shire.—Medical Officer and Public Vaccinator. Salary £135 per annum.

LOWESTOFT AND NORTH SUFFOLK HOSPITAL.—House-Surgeon (male). Salary £120 per annum.

MANCHESTER: AXLOTT'S HOSPITAL.—House-Surgeon (Orthopaedic). Salary £100 per annum.

MANCHESTER ROYAL EYE HOSPITAL.—Two Junior House-Surgeons. Salary £120 per annum.

MANCHESTER ROYAL INFIRMARY.—Assistant Medical Officer. Salary £35 per annum.

MANCHESTER: ST. MARY'S HOSPITALS.—Two House-Surgeons for the Whitworth Street West Hospital (Maternity).

MANCHESTER: UNION.—Junior Resident Assistant Medical Officer (female) at the Booth Hall Infirmary for Children. Salary at the rate of £275 per annum.

MARGATE: ROYAL SEA BATHING HOSPITAL.—Two Male House-Surgeons. Salary at the rate of £200 per annum.

METROPOLITAN ASYLUMS BOARD: TUBERCULOSIS SERVICE.—Junior Assistant Medical Officer (male) at St. Luke's Hospital, Lowestoft. Salary £500 per annum.

NORWICH CITY.—Clinical Tuberculosis Officer, Assistant Medical Officer of Health, and Assistant School Medical Officer. Salary £750.

enter on the next regular certificate issued to the patient a statement that dental treatment is recommended. But most practitioners will be quite willing, even without charging a fee, to help their patients in this regard without any narrow insistence on this limited obligation. The benefit ordinarily consists of payment by the society of the whole cost of operative treatment and not less than half the cost of dentures; but owing to lack of funds set aside for this purpose certain societies have been authorized to pay only 75 per cent. of the cost of operative treatment; and some have been obliged temporarily to suspend the benefit altogether. This treatment may be obtained by the patient from any registered dentist who is working under the scheme. In order to obtain a grant the member must ordinarily, before any treatment is begun, have submitted the dentist's estimate to the society and have obtained the society's authorization.

The scale of charges agreed upon is no concern of the medical profession. There are some indications that at the moment it is more satisfactory to the dentists than to the societies. The scale of charges for anaesthetics is, however, of some interest. It is not binding on any medical man, and has, in fact, been repudiated entirely by the British Medical Association. It contains two provisions which are of an extraordinary, not to say ludicrous, character. One of these is that where there are extractions from both jaws the anaesthetic fee is to be higher than if the extractions are from one jaw only. The other is that only one administration fee is to be charged to each patient, even if that patient requires more than one administration. No explanation of these remarkable provisions has, so far as we know, ever been vouchsafed. The actual fees prescribed are: (1) simple administration of nitrous oxide or similar anaesthetic, one jaw 7s. 6d., both jaws 10s.; (2) prolonged anaesthesia where not less than twelve teeth are extracted at one operation, £1 1s. These are the fees on which the dentist must estimate, and which will be paid to him if the society accepts his estimate. If he employs a medical practitioner as anaesthetist it is to be presumed that he will not be very willing to pay the anaesthetist larger fees than he will himself be allowed, and he is not allowed to charge his patient any larger fees than these. If, however, the patient himself asks to have his own medical attendant as anaesthetist, and the fee is in excess of those mentioned, the dentist may arrange this with the doctor and charge the excess to the patient.\* The choice of an anaesthetist rests with the dentist. A knowledge of the conditions set out above may be useful to medical anaesthetists arranging their fees with the dentist. In all cases of prolonged anaesthesia the anaesthetist must be "either a medical practitioner or a dentist (other than the dentist performing the extractions) skilled in the administration of a suitable general anaesthetic and included in a list to be approved by the Dental Benefit Joint Committee." As we previously pointed out, the obvious ambiguity of this provision would be completely avoided by the insertion of a comma after the words "medical

practitioner." For some reason the Joint Committee have preferred not to insert the comma, but to explain elsewhere that the proviso applies only to a dentist and not to a medical practitioner. Even so, the explanation is expressed incorrectly. The handbook states (p. 15) "any registered medical practitioner, therefore, is entitled to receive the fee under Item 5 (b) (ii) irrespective of the inclusion of his name in the panel." The medical practitioner, it cannot be too clearly understood, has no rights or duties under this scheme at all. What is meant is that the dentist has the right to employ a medical practitioner as anaesthetist and to receive the prescribed fee in respect of the administration. The difference is not negligible.

There are two points worth noting in connexion with possible developments of the medical insurance service. One is an important difference of function between the regional dental officer and the regional medical officer. The former may be (it seems, usually is) required to judge of the propriety of the dental treatment which his professional colleague proposes to give his patient, and of the quality and success of such professional work after it has been given. This seems, on the face of it, a highly undesirable state of affairs, and if it must be accepted by the best dentists as a regrettable necessity with regard to dental work and in the present conditions of the dental profession, it cannot be too emphatically stated that inspectorial functions analogous to these would never be tolerated for a moment by the medical profession. The second point is the statement of the joint committee with regard to dental clinics. The committee does not express any definite opinion on the question of the general institution of dental clinics, but "recommends that an experimental clinic or clinics be set up in a suitable area or areas, if possible under the supervision of the Minister of Health or the Scottish Board of Health," and says that "the steps necessary to give effect to this recommendation are now being taken by the committee." We made some comment on such a proposal in the JOURNAL of August 27th, 1927 (p. 355).

## Correspondence.

### Ophthalmic Clinics for Insured Persons.

SIR,—The letter in the SUPPLEMENT of December 24th, 1927, from Dr. Bickerton is so misleading that I feel obliged to reply to it. I do not agree with the policy of the Ophthalmic Committee of the British Medical Association; in my opinion they are making a fatal mistake in advocating clinics. Already there are signs that some societies are taking advantage of the favour shown by the British Medical Association to the clinic system and are actually starting clinics themselves, which are, as might have been expected, entirely controlled by these societies.

It is all very well to divide societies into good and bad, but it is a false division. A society formed from members in a good social position has a far lower sickness rate than one formed from members of an unhealthy trade. The surplus varies in different societies. One can afford to give its members extra benefits, whereas another finds itself with no surplus funds. Are we to label the latter a "bad" society on this account? It is no good to argue that as there is a surplus of over one hundred millions in the National Insurance Fund therefore the societies can afford to pay the fee required. The fees are paid by individual societies, and not by the national fund.

The fault of the whole matter is that we have not consented to let certain varieties of defects of sight, mainly cases of presbyopia, go to opticians. It is ridiculous to send every patient, without any discrimination, to an ophthalmic surgeon. The Panel Conference recognized this, and voted accordingly. The dictum, "Send all cases to an ophthalmic surgeon," must be modified. As was stated to the Panel Conference by a representative of the Ministry, it is impossible to pay for this. The only other way of overcoming the difficulty is to treat cases of presbyopia at a lower fee than the guinea.

To compare school clinics with those that are proposed for societies is a very poor argument. School children are all under one authority, and are treated in most areas by whole-time men as a part of their duty as school medical officers. Suitable

\* This statement is in accordance with the paragraph in the body of the "Dental Benefit Handbook," page 16: "Enquiries have been received as to the proper procedure in cases of simple administration in which insured persons desire to have their own doctors, either to administer the general anaesthetic or to be present at its administration by the dentist. It has been agreed that in the first type of case the payment of the doctor's fee is a matter for arrangement between the patient and the dentist, the patient paying to the dentist the difference, if any, between the doctor's fee and the administration fee payable by the society, and the dentist then making himself responsible for the payment of the whole fee to the doctor." But see page 50, under "Summary of the principal decisions of the Interpretation Committee":

"Case No. 955. If a patient desires to employ his or her own medical attendant to administer ordinary nitrous-oxide gas, and is willing to pay the fee, is this permissible under the scale?—Decision: If the patient desires to employ his or her own anaesthetist for the ordinary administration of nitrous oxide the patient is liable and must pay the anaesthetist's fee, the dentist charging only the scale fee for the extraction." Some further explanation seems called for.

premises and apparatus are provided by the education authorities, and the children can be dealt with at certain hours in the lump. To compare the two is to suggest that the societies shall set up clinics and work on the same system, which would be disastrous.

We have got to get our living and to protect our profession from being exploited. Does the writer of the letter consider the fees suggested as suitable for clinic work to be at all satisfactory? I think they are an insult. The result of starting clinics will be to lower the whole status of ophthalmic work. How futile it is to suggest that the members should pay the difference between the clinic fee and that of an ophthalmic surgeon if they want the latter! At the present day working men are out to get everything for little or nothing. How many will pay the extra fee?

Then, in the last paragraph, the writer states: "At present those who do not like the clinic scheme need not undertake the work." This is to say that if a clinic is established in the town where I reside I am to lose all my ophthalmic work if I do not join the clinic. That is a nice brotherly position to take up, is it not? If the clinic system is adopted the societies will obtain control, put in the medical man who is willing to do the work at the cheapest rate, and the rest can go to the devil!

If hospital ophthalmic surgeons are so foolish as to do work for nothing, for which they would be paid if they went about it in the right way, it is only another example of the lack of business aptitude of medical men. Every hospital ophthalmic surgeon should put his foot down and say, "I will not treat members of societies at the hospital." If they do not do this they are acting unfairly to themselves and to other colleagues who depend partly on ophthalmic work for a living.

I trust that clinics will not be established. It is by far the best plan to stick to the guinea fee and see the patients at our own rooms, making a modified charge for simple cases, such as presbyopia, or letting them go at their own risk to an optician.

I am afraid the Ophthalmic Committee of the British Medical Association has too many ophthalmic surgeons as members to the exclusion of those who are familiar with panel work and know the conditions of general practice in connexion with the panel. There are many men who have taken up refraction work as a sideline; these should be represented.—I am, etc.,

Hastings, Dec. 27th, 1927.

ARTHUR E. LAUKING.

## WILLIAMS-FREEMAN PRESENTATION FUND.

The following is the fourth list of subscriptions received in response to the letter published in our columns of October 1st, 1927 (p. 139):

Amount previously acknowledged ...	£	s.	d.

Total to January 2nd (morning) £1,661 18 6

Cheques should be made payable to the Williams-Freeman Presentation Fund, and addressed to Dr. D. G. Greenfield, Treasurer, c/o the Medical Secretary, British Medical Association, British Medical Association House, Tavistock Square, London, W.C.1.

## Naval and Military Appointments.

### ROYAL NAVAL MEDICAL SERVICE.

Surgeon Lieutenant Commanders F. G. Hunt to the *Tamar* for Hong-Kong Dockyard; J. H. Vey to the *Victory* for Portsmouth Dockyard; C. T. Hyatt to the *Vindicta*.  
Surgeon Lieutenants D. Duncan to the *Fernon*; J. H. Nicolson to the *Tiger*, temporary, and to the *Connaught* on commissioning with full complement; S. G. Weldon to the *Alceste*, temporary.

### ROYAL ARMY MEDICAL CORPS.

Colonels G. M. Goldsmith, C.B.E., and H. D. Packer, C.I.E., late R.A.M.C., retire on retired pay.  
Colonel R. H. Lloyd, late R.A.M.C., is placed on half pay under the provisions of Articles 139 and 463, Royal Warrant for Pay and Promotion, 1926.

Lieutenant-Colonel from R.A.M.C. to be Colonels: E. McDonnell, D.S.O., vice Colonel G. M. Goldsmith, C.B.E., to retired pay; Brevet Colonel A. H. Safford, vice Colonel R. H. Lloyd to half pay; Brevet Colonel J. W. West, C.M.G., K.H.S., vice Colonel H. D. Packer, C.I.E., to retired pay.

Lieut.-Colonel A. McNunn, O.B.E., having attained the age fixed for compulsory retirement, retires on retired pay.

Majors to be Lieutenant-Colonels: N. Low, D.S.O., O.B.E., vice Lieut.-Colonel E. McDonnell, D.S.O., promoted; A. N. Fraser, D.S.O., vice Lieut.-Colonel and Brevet Colonel A. H. Safford, promoted; R. H. L. Gardner, vice Lieut.-Colonel and Brevet Colonel J. W. West, C.M.G., K.H.S., promoted.

Captain O. T. Gimlette to be Major (prov.).

Temporary Lieutenant O. A. Owen-Flood (Lieutenant, Regular Army Reserve of Officers, Royal Irish Fusiliers) relinquishes his temporary commission.

### ROYAL AIR FORCE MEDICAL SERVICE.

The promotion of the following officers is announced in the Supplement to the *London Gazette* of January 2nd, containing the list of New Year Honours, etc.: Wing Commander E. C. Clements, O.B.E., to be Group Captain; Flight Lieutenant (Acting Squadron Leader) J. N. MacDonald to be Honorary Wing Commander.

Flight Lieutenants O. J. Griffiths to R.A.F. Station, Bicester; D. B. Smith to Station Headquarters and Storage Section, Andover.

### INDIAN MEDICAL SERVICE.

The services of Lieut.-Colonel G. W. Macdonachie have been placed at the disposal of the Government of Bihar and Orissa, for employment as Officiating Inspector-General of Prisons, Bihar and Orissa.

On reversion from the cadre of Agency Surgeons under the Government of India in the Foreign and Political Department, the services of Major C. J. Stocker, M.C., are placed temporarily at the disposal of the Government of the Central Provinces.

The services of Captain M. T. Khandwalla are placed temporarily at the disposal of the Government of Madras for employment in the Jail Department.

Lieut.-Colonel W. H. C. Forster to be Colonel, vice Colonel A. Fenton, retired.

Lieutenant J. H. Clapp to be Captain.

Lieut.-Colonels T. S. Norris, V.H.S., and W. F. Harvey, C.I.E., have retired from the service.

## VACANCIES.

BOURNEMOUTH: ROYAL VICTORIA AND WEST HINTS HOSPITAL.—House-Surgeon (male) for the Boscobel Branch. Salary £120 per annum.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd Street, W.C.1.—(1) Two Out-patient Officers; remuneration at the rate of £150 per annum. (2) Junior House-Surgeon; salary at the rate of £50 per annum.

CRYSTON COUNTY BOROUGH.—Assistant Medical Officer of Health and Assistant School Medical Officer. Salary £600 per annum.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Honorary Gynaecologist.

EXETER: ROYAL DEVON AND EXETER HOSPITAL.—Senior House-Surgeon (male). Salary £200 per annum.

FREEMANS HOSPITAL AND NURSING HOME, 237, Fulham Road, S.W.3.—Resident Medical Officer (male). Salary at the rate of £250 per annum.

GLASGOW ROYAL CANCER HOSPITAL.—Research Worker. Salary £800 to £1,000 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.3.—Two House-Physicians. Honorarium £50 for six months.

IPSWICH: EAST SUFFOLK AND IPSWICH HOSPITAL.—Casualty Officer (male). Salary £150 per annum, rising to £200.

KENSINGTON, FULHAM, AND CHELSEA GENERAL HOSPITAL.—Honorary Dental Surgeon (male).

LEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £150 per annum.

LINCOLN: THE LAWN.—Medical Superintendent. Salary £700 per annum.

LOCHVARRON PARISH COUNCIL, Ross-shire.—Medical Officer and Public Vaccinator. Salary £133 per annum.

LOWESTOFT AND NORTH SUFFOLK HOSPITAL.—House-Surgeon (male). Salary £120 per annum.

MANCHESTER: AXLOTT'S HOSPITAL.—House-Surgeon (Orthopaedic). Salary £100 per annum.

MANCHESTER ROYAL EYE HOSPITAL.—Two Junior House-Surgeons. Salary £120 per annum.

MANCHESTER ROYAL INFIRMARY.—Assistant Medical Officer. Salary £35 per annum.

MANCHESTER: ST. MARY'S HOSPITALS.—Two House-Surgeons for the Whitworth Street West Hospital (Maternity).

MANCHESTER UNION.—Junior Resident Assistant Medical Officer (female) at the Booth Hall Infirmary for Children. Salary at the rate of £275 per annum.

MARGATE: ROYAL SEA BATHING HOSPITAL.—Two Male House-Surgeons. Salary at the rate of £200 per annum.

METROPOLITAN ASYLUM BOARD: TUBERCULOSIS SERVICE.—Junior Assistant Medical Officer (male) at St. Luke's Hospital, Lowestoft. Salary £500 per annum.

KORWICK CITY.—Clinical Tuberculosis Officer, Assistant Medical Officer of Health, and Assistant School Medical Officer. Salary £750.

OLDHAM COUNTY BOROUGH.—Resident Assistant Medical Officer of Health. Salary £450 per annum.

ROYAL LONDON OPHTHALMIC HOSPITAL, City Road, E.C.1.—Assistant Surgeon. ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester Square, W.O.2.—Pathologist (male), part-time. Honorarium £150 per annum and a proportion of teaching fees.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, Otty Road, E.C.1.—House-Surgeon (male). Salary at the rate of £75 per annum.

ST. PANCRAS DISPENSARY, 39, Oakley Square, N.W.—Resident Medical Officer. Salary £185 per annum.

SEAMEN'S HOSPITAL SOCIETY.—Honorary Assistant Physician at the Hospital for Tropical Diseases, Endsleigh Gardens, W.O.

SHANGHAI MUNICIPAL COUNCIL.—Assistant Pathologist in the Public Health Department. Salary 600 taels per mensem.

SYDNEY: PRINCE ALFRED HOSPITAL.—Pathologist. Salary £700 for first year, and £800 for remaining years.

TAUNTON AND SOMERSET HOSPITAL.—Senior and Junior House Medical Officers (male). Salary at the rate of £150 and £100 per annum respectively.

VICTORIA HOSPITAL FOR CHILDREN, Tite Street, S.W.3.—(1) House-Physician and House-Surgeon; salary at the rate of £100 per annum. (2) Two Out-patient Anaesthetists; payment 10s. 6d. per attendance.

WATFORD: PEACE MEMORIAL HOSPITAL.—Resident Medical Officer (male). Salary at the rate of £150 per annum.

WEST END HOSPITAL FOR NERVOUS DISEASES.—Senior House-Physician. Salary at the rate of £150 per annum.

CERTIFYING FACTORY (announced: Dollar appointments are to the Chief I. (nurses). Applications Whitehall, S.W.1.

MEDICAL REFURGE UNDER THE WORKMEN'S COMPENSATION ACT for the Districts of Blandford, Bridport, Dorchester, Ringwood, Lynton, Poole, and Weymouth, and Wimborne Minster County the Private Secretary, Home Office, Whitehall, S.W.1.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

### APPOINTMENTS.

HOLDEN, Oscar M., M.D.Birm., D.P.H., Medical Officer of Health for Croydon.

MILLER, J. Wilson, M.B., Ch.B.Glas., D.P.H.Camb., Medical Officer of Health for the Borough of Lewisham.

MORRIS, H. M., M.D.Belf., D.M.R.E.Liverp., Honorary Radiologist to the Eccles and Patricroft Hospital, Manchester.

NOON, Charles, F.R.C.S.Eng., Honorary Surgeon to the Patrick Stead Hospital, Halesworth, Suffolk.

YULE, John, M.B., Ch.B.Glas., Assistant Port Medical Officer to the Hull and Goole Port Sanitary Authority.

### DIARY OF SOCIETIES AND LECTURES.

#### ROYAL SOCIETY OF MEDICINE.

Section of Therapeutics.—Tues., 5 p.m.

Section of Psychiatry.—Tues., 8.30 p.m., Dr. William Brown; Theories of Suggestion.

Section of Medicine.—Wed., 8.15 p.m., Naso-oral Sepsis on the Lungs and "E. D. D. Davis and Mr. C. A. S. and Dr. T. Izod Bennett (Medicine) Bullied (Odontology). Clinical Meeting at the National Cases. 8.30 p.m., Mr. W. Stewart aocular Pressure; Mr. Montague L. of the Eyelid and of an Artificial Oral Nerve and its Clinical Significance.

HARVEIAN SOCIETY, 11, Chandos Street, W.1.—Thurs., 8.30 p.m., Annual General Meeting.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.—Mon., 8.30 p.m., Pathological Evening.

WEST KENT MEDICO-CHIRURGICAL SOCIETY, Miller General Hospital, Greenwich, S.E.—Fri., 8.45 p.m., Clinical Meeting.

### POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Royal Eye Hospital, St. George's Circus, S.E.1.—Wed., 5 p.m., Special Clinical Demonstration in Ophthalmology; open to all members of the medical profession. In Medicine, Surgery, and the Specimen Lectures, Ward Rounds, and Operations; fee 15 5s. for two weeks, or 13 3s. for one week. Children's Clinic, and other hospitals: Post-graduate Course in Diseases of Children, mornings and some afternoons; fee 12 2s.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn Road, W.C.1.—Wed., 4 p.m., Consultations and Demonstrations of Interesting Cases. Fri., 4 p.m., Museum Specimens.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester Square, W.C.2.—Thurs., 5 p.m., Ringworm Infections.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.—Mon., 2.30 to 5 p.m., Medical, Surgical, and Gynaecological Clinics; Surgical, Throat, Nose, 2.30 to 5 p.m., Medical, Skin, and Dental Clinics, 2.30 to 5 p.m., Throat Clinics; Operative Clinics; 2.30 to 5 p.m., Diseases of the Ear, Nose, and Throat; Operations.

ROYAL NORTHERN HOSPITAL, Holloway Road, N.—Tues., 3.15 p.m., (1) Pathological Specimens; (2) Clinical Pathology.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.—Mon., 10 a.m. to 1 p.m., Genito-urinary Operations, Skin Department, Surgical

Wards; 2 p.m., Surgical Wards, Gynaecological and Eye Departments; 4.30 p.m., Special Lecture: Dysentery. Tues., 10 a.m. to 1 p.m., Medical Ward VI. Throat, Medical Wards, m., Children's Medical Pathology; 2 1 p.m., Eye and 10 a.m. to 10 a.m. t Department. Medical and Surgical Out-patients at 2 p.m.

### British Medical Association.

#### CURRENT NOTES.

##### Illustrations in the "Journal."

DURING the Annual Representative Meeting in Edinburgh a motion was brought forward by the Edinburgh and Leith Division requesting the Council to consider the possibility of improving the general quality of the illustrations appearing in the *BRITISH MEDICAL JOURNAL*. After an explanation had been given by the Chairman of the Journal Committee, in the course of which he emphasized the expense involved in reproducing pictures on special art paper, the motion was withdrawn.

This is a matter to which a great deal of attention has been given, and the efforts to obtain good results will not be relaxed. Pen-and-ink drawings that can be reproduced in line blocks are easily dealt with. The root of the difficulty is that nowadays most of the pictures submitted are photographs, and that they are not taken with a view to reproduction on a rapid press, as are those produced by journalist-photographers for the daily press. The situation was discussed again at the last meeting of the Journal Committee, when the opinion was expressed that some good might be done if an appeal were made to contributors to realize that some of the difficulties in the way of satisfactory reproduction of photographs in the *JOURNAL* can only be overcome if they will give their assistance.

Many of the illustrations sent for reproduction are very far from being suitable. Snapshots taken with a hand camera are a very severe test of a photographer's skill; few amateurs can in this way produce a print suitable for reproduction on the printed page or even on special art paper. For photographs of patients it is best to use a portrait lens. Usually it is preferable to employ a photographer accustomed to portrait work. Care should be taken that the subject is properly lighted and shown against a flat uniform background. The whole effect of photography is in the contrast between the black and white. In most cases a smoothly stretched sheet, white or grey, gives the best contrast; an ordinary wall with fittings in or upon it, or a curtain hanging in folds, are most unsuitable. Satisfactory process reproductions of anatomical details or of *post-mortem* appearances can seldom be obtained from photographs; drawings in black and white without a wash will usually give all the details requisite, and are preferable to photographs or wash drawings. It is often as difficult to get a good result from a wash drawing as from a photograph. Descriptive details should not be written on a photograph or a drawing; reference letters in the margin, with lines to the point to which it is desired to direct attention, should be pencilled in faintly, and the description given in the legend.

The following rules from two contemporaries indicate the view taken by other editors and printers:

*The Biochemical Journal*: "Illustrations and curves accompanying papers must be carefully drawn, about twice the size of the finished block, on smooth white Bristol boards in Indian ink. Any lettering on these drawings should be lightly inserted in pencil."

*The Journal of Physiology*: "Figures should be ready for photographic (that is, process) reproduction. Diagrams should be in Indian ink, and plain white or faint blue-lined paper only should be employed; letters, numbers, etc., should be written in pencil."

#### Subscriptions for 1928.

Members of the British Medical Association are reminded that subscriptions fall due on January 1st in each year, and that if each member on receiving an application for his or her subscription from the Head Office would send the amount to the Financial Secretary without delay the work of the office would be very considerably lightened. Members are also reminded of the claims of charity. The amounts at the disposal of those who administer medical benevolence are altogether insufficient to deal adequately with the cases needing help, and the British Medical Association Charities Fund was formed in order to assist. Contributions are urgently needed, and all members are asked to add to their next payment a sum for the credit of that Fund.

### Association Notices.

#### BRANCH AND DIVISION MEETINGS TO BE HELD.

**BORDER COUNTIES BRANCH: DUMFRIES AND GALLOWAY DIVISION.**—The next meeting of the Dumfries and Galloway Division will be held in the Royal Infirmary, Dumfries, on Friday, January 27th, at 4 p.m., when finance, hospital accommodation, ethical questions, medical charities, and other important matters will be considered. The Executive Committee will meet at 3 p.m. Professor Bramwell has fixed February 21st as the date of his lecture, the subject of which will be announced later.

**BORDER COUNTIES BRANCH: ENGLISH DIVISION.**—A meeting of the English Division will be held at Maryport on Friday, January 27th. Dr. J. N. Douglas Smith will read a paper on the early treatment of puerperal sepsis.

**CAMBRIDGE AND HUNTINGDON BRANCH.**—A meeting of the Cambridge and Huntingdon Branch, in conjunction with the Cambridge Medical Society, will be held at the Addenbrooke's Hospital, Cambridge, to-day (Friday, January 13th), at 2.30 p.m. The meeting will be devoted to the exhibition of clinical cases and pathological specimens.

**DORSET AND WEST HANTS BRANCH: WEST DORSET DIVISION.**—A meeting of the West Dorset Division will take place at the County Hospital, Dorchester, on Thursday, January 19th, at 3.30 p.m. Agenda: Cases; election of representative and deputy representative for 1928-29. Tea will be served by the courtesy of the medical and surgical staff of the hospital. Mr. P. Jenner Verrall will deliver a British Medical Association Lecture entitled "Manipulative surgery," at 4.30 p.m. Criticism and discussion are invited. Members unable to get to the meeting by 3.30 p.m. will, it is hoped, attend the lecture at 4.30.

## Range of Medical Service.

[SUPPLEMENT TO THE  
BRITISH MEDICAL JOURNAL]

**ESSEX BRANCH: NORTH-EAST ESSEX DIVISION.**—A clinical meeting of the North-East Essex Division will be held in the out-patients' hall in the Essex County Hospital, Colchester, on Thursday, January 26th, at 8.15 p.m. Professor W. E. Dixon will give an address on the known effects of alcohol in the human body.

**FIFE BRANCH.**—A clinical meeting of the Fife Branch will be held in the Maternity Home, Townsend Crescent, Kirkcaldy, on Thursday, January 26th, at 3.30 p.m. Sir David Wallace will give an address on orthopaedic treatment and organization in the East of Scotland.

**KENT BRANCH: ASHFORD DIVISION.**—The next meeting of the Ashford Division will be held in the North Street Club on January 18th at 4 p.m., when a lecture will be given by Mr. T. G. Taunton, orthopaedic surgeon at Rochester Hospital, on orthopaedics in general practice.

**KENT BRANCH: DARTFORD DIVISION.**—A meeting of the Dartford Division will be held on Wednesday, January 25th. Dr. Lindsay W. Battin will give a British Medical Association Lecture on the medical aspects of child welfare clinic work.

**LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.**—A clinical meeting of the Hyde Division will be held in the Maternity and Child Welfare Centre, Hyde, on Thursday, January 26th, at 8.30 p.m.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—A clinical meeting of the City Division will be held to-day (Friday, January 13th), at 4.15 p.m., when Dr. Norman Hill will show cases. Tea.

**METROPOLITAN COUNTIES BRANCH: LAMETHIC AND SOUTHWARK DIVISION.**—A meeting of the Lambeth and Southwark Division will be held at the Lambeth Carlton Club, Coldharbour Lane, S.W.9, on Wednesday, January 25th, when Dr. A. G. G. Thompson, the newly appointed medical officer of health for Lambeth, will read a paper on the Schick test.

**METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.**—A clinical evening arranged by the Lewisham Division will be held at the South-Eastern Children's Hospital, Sydenham, on Tuesday, January 17th.

**METROPOLITAN COUNTIES BRANCH: MARYLEBONE DIVISION.**—By the kind invitation of Mr. H. S. Wellcome a meeting will be held at the Wellcome Historical Museum, 54A, Wigmore Street, W.1, on Wednesday, January 18th, at 8.15 p.m., when the conservator, Mr. Malcolm, will demonstrate in the various sections of the museum. Ladies are invited, and Mr. Wellcome has kindly offered to provide hospitality. Members proposing to bring guests are asked to notify Dr. W. Griffith (honorary secretary), 1, Harley Street, W.1.

**METROPOLITAN COUNTIES BRANCH: NORTH MIDDLESEX DIVISION.**—At the meeting of the North Middlesex Division to be held on Wednesday, January 25th, Mr. T. H. C. Bonas will read a paper on local immunization and antiviral therapy.

**METROPOLITAN COUNTIES BRANCH: STRATFORD DIVISION.**—A meeting of the Stratford Division will be held in the Board Room, Educational Offices, The Grove, Stratford, on Tuesday, January 17th, at 9.15 p.m. Dr. Theodore Thompson, physician to the London Hospital, will give a lecture on some practical points in the examination of cases for life assurance. It is hoped that every member of the Division will make an effort to attend.

**METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.**—A meeting of the Willesden Division will be held at the Willesden General Hospital, Harlesden Road, N.W., on Wednesday, January 18th, at 9 p.m. Dr. Christine Murrell will discuss the question of nursing homes for middle-class patients.

**NORTH OF ENGLAND BRANCH: BISHOP AUCKLAND DIVISION.**—A meeting of the Bishop Auckland Division will be held at the Cottage Hospital, Bishop Auckland, on Friday, January 27th, at 8 p.m. Dr. J. C. Spence will give a lecture on medical emergencies in children.

**OXFORD AND READING BRANCH: OXFORD DIVISION.**—A meeting of the Oxford Division will be held in the Radcliffe Infirmary on Wednesday, January 25th, at 2.30 p.m. Dr. T. Izod Bennett will lecture on recent advances in pernicious anaemia.

**SOUTHEAST BRANCH: JERSEY DIVISION.**—A meeting of the Jersey Division will be held at the General Hospital on Thursday, January 19th, at 8.30 p.m. Dr. H. W. Marrett will read a paper on heredity in relation to social problems.

**SOUTHEAST BRANCH: PORTSMOUTH DIVISION.**—A meeting of the Portsmouth Division will be held on Thursday, February 9th. A British Medical Association Lecture will be delivered by Professor Hugh Maclean on renal disease and high blood pressure.

**SOUTH WALES AND MONMOUTHSHIRE BRANCH.**—A clinical meeting of the South Wales and Monmouthshire Branch will be held in the Royal Gwent Hospital, Newport, on Thursday, January 19th, at 4 p.m.

**SOUTH-WESTERN BRANCH.**—An intermediate meeting of the South-Western Branch will be held in the Library of the Royal Devon and Exeter Hospital, on Thursday, January 19th. Members desiring to bring forward cases, notes, papers, specimens, or notices of motion are asked to notify the honorary secretary, Dr. P. D. Warburton, 15, Southernhay East, Exeter, in order that they may be placed on the agenda paper.

**SURREY BRANCH: CROYDON DIVISION.**—A meeting of the Croydon Division will be held at the Croydon General Hospital on Tuesday, January 17th, at 8.30 p.m. Dr. Edward Bach will read a paper on some interesting facts concerning intestinal toxæmia.

**WEST SOMERSET BRANCH.**—A clinical meeting of the West Somerset Branch will be held at the Taunton and Somerset Hospital on Tuesday, January 24th, at 3.30 p.m. A paper open to discussion will be read by Dr. W. H. Maidlow (Minister) entitled "A to Z. Subjects of interest to the general practitioner." Tea will be served at 4.30 p.m.

**YORKSHIRE BRANCH: DEWSBURY DIVISION.**—A meeting of the Dewsbury Division will be held at the Dewsbury Infirmary on Friday, February 3rd, at 8.15 p.m. Dr. G. Cooper (Leeds) will read a paper on radiotherapy.

**YORKSHIRE BRANCH: LEEDS DIVISION.**—A meeting of the Leeds Division will be held in the General Infirmary, Leeds, on Friday, February 17th, at 8 p.m. Dr. John Parkinson will give a British Medical Association Lecture on common difficulties in cardiac diagnosis. Lantern slides will be shown, and there will be a discussion after the lecture.

## National Insurance.

RANGE OF MEDICAL SERVICE.  
AN OPERATION FOR HAMMER-TOE.

We have received a copy of the report to the Minister of Health of a decision of referees, pursuant to Article 38 of the Medical Benefit Consolidated Regulations, 1924, on the question whether amputation of the second toe at the metatarsophalangeal joint as a cure for hammer-toe is included in the range of medical service within the meaning of that Article and Clause 8 of the Terms of Service for insurance practitioners. The referees were Mr. E. H. Tindal Atkinson (barrister-at-law), Dr. Alexander Forbes, and Dr. John Steed.

The operation had been performed by Dr. S. Depree of Blackpool, and the fact that the patient was an insured person on his list was not communicated to him until after the operation; but in the referees' view this circumstance did not affect the general question submitted for their decision. Both the Local Medical Committee and the Insurance Committee for the county borough of Blackpool were in agreement that this operation was outside the range of medical service.

The inquiry was held at Blackpool on November 25th, 1927. Mr. L. G. Dawson represented the Minister of Health, and Dr. H. T. Barton represented the Minister of Health, and Dr. Depree's qualifications as those of a specialist in surgical operations of this class the referees expressed themselves as satisfied that from his experience he does in fact possess the special skill required to perform this operation.

On the main issue the contentions put forward on the part of the Minister were that (a) this operation is of a simple character, and is and should be well within the competence of a general practitioner; (b) the operator need have no assistance other than that of the anaesthetist; (c) in a normal case the operation can well be performed at the patient's residence, although its performance in a nursing home or hospital may be advantageous in that better nursing facilities would then be available. Medical witnesses called in support of these contentions. They expressed the view that this was a simple minor surgical operation of such a character that any general practitioner should be able to perform it, and that the operation could usually be undertaken without risk at the patient's home.

The contentions of Dr. Barton, on behalf of the committees were that: (a) In the Blackpool area very little minor surgery is undertaken by insurance practitioners. (b) Local housing conditions are of such a character as to render it inadvisable in ordinary cases to undertake this operation elsewhere than in a hospital or nursing home owing to the importance of obtaining aseptic conditions. (c) In the best interests of the patient it is better that the operator should have an assistant other than the anaesthetist. (d) Taking into account these factors the insurance practitioners in the Blackpool area reasonably regard this operation as outside the range of medical service, and in effect there exists a local custom in this area which the referees should take into account under Clause 8 (4) of the Terms of Service. In support of these contentions Dr. Barton called medical witnesses, who emphasized the necessity of asepsis in a bone operation, and although not regarding the operation *per se* as a difficult one, expressed the opinion that general practitioners in the district did not perform operations of this kind, but preferred, in the interests of the patient, that such an operation should be performed in a nursing home or a hospital. One witness considered that it should be undertaken by a doctor in active surgical practice. It further appeared from the evidence that, comparatively speaking, the necessity for this operation is rare in this district.

The referees, in the course of their decision, say that they regard the issues raised as difficult in that they involve the application of Clause 8 (4) of the Terms of Service to a case in which a minor surgical operation is involved. Viewing the matter simply in relation to a criterion which measures the difficulty and degree of skill involved, they accept the view that the operation is simple, and of such a character that it is reasonable to expect its performance at the hands of an average general practitioner. They do not attach much weight to the plea that in the best interests of the patient the operation should be performed in a nursing home or a hospital, and should, therefore, be excluded from the range of service.

"It is obvious that, generally speaking, any operation would be better performed in such surroundings rather than in the patient's home, but to test the range of medical service solely by this consideration would lead to absurdity, nor would it determine the

right of a practitioner to charge a fee. We doubt not that in a proper case—for example, where the local surroundings are wholly unfavourable—the doctor could justifiably insist that, while charging no fee for the service, he should be permitted to operate under more favourable conditions."

On the question of local custom and the weight that should be attached thereto, the referees express the view that no mere agreement among local practitioners to regard a particular operation as outside their contract ran by itself give rise to a local custom. Such an agreement would constitute them the arbiters in the very issue which arises in these inquiries.

"On the other hand, it is clearly necessary to recognize a differing standard of skill in operative work in accordance with local conditions—for example, in a manufacturing district, say twenty miles from a hospital, a higher standard of skill may reasonably be attributed to the practitioner than to one whose experience is limited by the class of persons he attends, and to a certain extent by the local facilities for expert treatment. And in this respect the comparative rarity of the occasions on which the necessity for this operation arises in the Blackpool area must be taken into account.

"There are, however, operations of such a simple character that it would be unreasonable, if not unnecessary, to invoke the provisions of Clause 8 (4) of the Terms of Service as affecting the main test laid down in Clause 8 (1). There appears to us to be some danger in using Clause 8 (4) to narrow the ambit of the services to be rendered by an insurance practitioner except in cases in which the operation itself may be regarded as on the border-line of difficulty—that is, when the skill of an average general practitioner is in question as a criterion.

"The necessity must arise on occasions for an operation of simple character to be performed as a remedy for some complaint which may in the particular district be of rare occurrence. In such circumstances we suggest that, if the operation, as measured by the main test, is comparatively easy, contentions as to a local custom should be examined with some caution. A too ready insistence on such custom would seem to us to be harmful to the broad principles upon which medical service under the National Health Insurance Act is founded."

Applying the foregoing considerations to this particular case the referees have, on the whole, come to the conclusion unanimously that the contentions advanced by the Minister should prevail, and that this particular service was within the range of medical service as laid down in the opening words of Clause 8 (1).

## Correspondence.

### Ophthalmic Clinics for Insured Persons.

Sir,—I was glad to see from various letters on the above subject that many ophthalmic surgeons are against the proposed clinics. For the past seven years I have had experience of clinics for school children under two education committees. In one case I am paid on a sessional basis, and in the other on a capitation basis. I find that, in the case of the clinic paid on the sessional basis, in order that at least eight "new" cases shall be present at each session, many more than eight are written to attend and, as a consequence, the average attendance of "new" cases is twelve or thirteen.

I fear that the same thing will happen in ophthalmic clinics for insured patients, and we shall be fortunate if the payment works out at 6s. per person examined. If an ophthalmic surgeon finds more than eight "new" cases at these clinics and he objects, I am afraid that the societies will bring pressure to bear to force him to examine as many cases as they care to send to the clinics. After all, if one should find ten or twelve cases at a session, one cannot very well go "on strike" after seeing eight cases and refuse to see the remainder.

If we are to have clinics, let us be paid on a capitation basis, and let the basis be at least half a guinea per case. As Dr. Gittings says, the Ophthalmic Committee of the British Medical Association seems determined to have clinics; but I suggest that before the committee goes any further it circularize the ophthalmic surgeons on the British Medical Association list, and ask for replies to the following questions:

(1) Are you in favour of the present system or the clinic system?

(2) If clinics are established, do you prefer to be paid on a sessional basis or on a capitation basis?

If the committee does that, then let us be content to abide by the decision of the majority.—I am, etc.,

ANOTHER OPHTHALMIC SURGEON.

## Naval and Military Appointments.

### ROYAL NAVAL MEDICAL SERVICE.

Surgeon Commander L. F. Cope, O.B.E., is placed on the retired list with the rank of Surgeon Captain.

Messrs. J. A. K. Fitzgerald, J. W. Nesbitt, A. D. Sinclair, E. R. P. Williams, and A. E. Kingston have entered as Surgeon Lieutenants for short service and appointed to the Victory for Haslar Hospital for course of instruction.

### ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Commander H. J. Murray to be Surgeon Captain.  
Surgeon Commander (retired) R. Willboud, V.D., to be Surgeon Captain (retired).

Surgeon Lieutenant Commanders L. C. D. Irvine and A. C. V. Elder, D.S.L., to be Surgeon Commanders.

Surgeon Lieutenant R. Hall to be Surgeon Lieutenant Commander.

Surgeon Lieutenants T. A. Brand to the *Bombay* for training; F. E. Stabler to the *Victory* for R.N. Hospital, Haslar, for fourteen days' training.

Probationary Surgeon Lieutenant R. L. Stubbs to be Surgeon Lieutenant. To be probationary Surgeon Lieutenants: C. C. Ungley, attached to List 2 of Tyne Division; R. D. Owen, attached to List 2 of Bristol Division.

To be probationary Surgeon Sublieutenants: E. P. Davies, E. C. Thomas, and D. G. Evans, attached to List 2 of Bristol Division; D. A. Williams.

### ROYAL AUSTRALIAN NAVY.

Surgeon Commanders W. E. Roberts to the *Victory* for R.N. Barracks; A. S. Mackenzie to the *Victory* for H.M.A.S. *Australia* for trials.

### ROYAL ARMY MEDICAL CORPS.

Major-Generals Sir Maurice P. C. Holt, K.C.B., K.C.M.G., D.S.O., late R.A.M.C., and Sir Samuel G. Guise-Moore, K.C.B., C.M.C., retired pay, late R.A.M.C., to be Colonel Commandants, vice Major-General Sir William Macpherson, K.C.M.G., C.B., and Lieut.-General Sir Arthur T. Sloggett, K.C.B., K.C.M.G., K.C.V.O.

Lieut.-Colonel A. C. Addeley, D.S.O., half-pay list, late R.A.M.C., retires on retired pay on account of ill health.

Major H. H. A. Emerson, D.S.O., to be Brevet Lieutenant-Colonel.

Major B. H. H. Neven-Spence retires on retired pay.

Lieutenant (on probation) T. F. M. Woods, from the second list, is restored to the establishment.

Temporary Lieutenant S. M. Burrows to be Lieutenant (on probation), and relinquishes the rank of temporary Lieutenant.

### ROYAL AIR FORCE MEDICAL SERVICE.

Squadron Leaders R. W. Ryan and F. E. Johnson to R.A.F. Depot, Uxbridge.

Flight Lieutenants C. V. D. Rose and T. V. O'Brien to R.A.F. Depot, Uxbridge; L. C. Palmer-Jones to No. 288 Squadron, Middle East.

Flying Officer J. Mgaer to Aircraft Depot, India.

### COLONIAL MEDICAL SERVICES.

Dr. R. T. B. Green appointed Second Pathologist, Institute for Medical Research, F.M.S. Dr. R. A. Pallister appointed Health Officer, Malayan Medical Service. Dr. R. Stuppel appointed Government Medical Officer, East. Dr. R. P. Crawford is confirmed in his appointment as Medical Officer, Nigeria. Dr. William E. Clorer promoted Senior Medical Officer in Nigeria. Dr. A. S. Westmorland appointed Senior Medical Officer, Public Hospital, Kingstown, Jamaica. Dr. H. O. Hopkins appointed Malaria Research Officer, Institute for Medical Research, F.M.S.

## VACANCIES.

BETHNAL GREEN HOSPITAL, E.2.—Assistant Medical Officer. Salary £350 per annum.

BIRMINGHAM CORPORATION.—Senior Assistant Medical Officer of Health. Salary £1,100 per annum.

BLUTH BOROUGH.—Medical Officer of Health; School Medical Officer, and Port Medical Officer. Salary £800 per annum, rising to £900.

BOURNEMOUTH: ROYAL VICTORIA AND WEST HANTS HOSPITAL.—House-Surgeon (male) for Boscombe Branch. Salary £120 per annum.

BRIGHTON: NEW SUSSEX HOSPITAL FOR WOMEN AND CHILDREN.—(1) Honorary Radiologist. (2) Honorary Surgeon to the Ear, Nose, and Throat Department.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—House-Physician (male). Salary at the rate of £130 per annum.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd Street, W.C.1.—(1) Two Out-patient Officers; remuneration at the rate of £150 per annum. (2) Junior House-Surgeon; salary at the rate of £50 per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E.2.—Physician to Out-patients.

COVENTRY CITY.—Deputy Medical Officer of Health. Salary £750 per annum, rising to £1,000.

CRYDON COUNTY BOROUGH.—Assistant Medical Officer of Health and Assistant School Medical Officer. Salary £600 per annum.

DURHAM COUNTY COUNCIL.—Medical Officer of Earl's House Sanatorium for Boys. Salary £450 per annum, rising to £500.

FREEMANS HOSPITAL AND NURSING HOME, 237, Fulham Road, S.W.3.—Resident Medical Officer (male). Salary at the rate of £250 per annum.

CONDON HOSPITAL FOR RECTAL DISEASES, Vauxhall Bridge Road, S.W.—Resident House-Surgeon. Salary £75 per annum.

HEMEL HEMSTEAD: WEST HENTS HOSPITAL.—Resident Medical Officer. Salary £150 per annum.

HUNTINGDON COUNTY HOSPITAL.—House-Surgeon (male). Salary £100 per annum.

LIVERPOOL: ROYAL LIVERPOOL CHILDREN'S HOSPITAL.—(1) Resident Medical Officer at the Hewell Branch; salary £120 per annum. (2) Two Resident House-Physicians and two Resident House-Surgeons at the City Branch; salary £60 per annum.

LOCHERNAON PARISH COUNCIL, Ross-shire.—Medical Officer and Public Vaccinator. Salary £133 per annum.

LONDON FEMALE LOCK HOSPITAL, 283, Harrow Road, W.9.—Second House-Surgeon. Salary £150 per annum.

MANCHESTER: ANCOATS HOSPITAL.—Resident Medical Officer. Salary £150 per annum.

MANSFIELD AND DISTRICT HOSPITAL.—Senior House-Surgeon (male). Salary £200 per annum.

MARGATE: ROYAL SEA BATHING HOSPITAL.—Two Male House-Surgeons. Salary £200 per annum.

METROPOLITAN HOSPITAL, Kingsland Road, E.8.—Ophthalmic Surgeon.

MIDLOTHIAN, WEST LOTHIAN, AND PEEBLES COUNTIES.—Medical Officer of Health. Salary £900 per annum.

MILDWAY MISSION HOSPITAL, Austin Street, E.2.—Junior Resident Medical Officer (male). Salary £100 per annum.

MINISTRY OF PENSIONS HOSPITAL, Crangthorpe, Manchester.—Junior Medical Officer (unmarried). Salary £300 per annum.

**NOTTINGHAM CHILDREN'S HOSPITAL.**—Resident House-Surgeon (woman). Salary at the rate of £150 per annum.

**NORWICH CITY.**—Clinical Tuberculosis Officer, Assistant Medical Officer of Health, and Assistant School Medical Officer. Salary £750.

**PERKINS HOUSE MENTAL HOSPITAL,** 112, Peckham Road, S.E.15.—Junior Assistant Medical Officer (male, unmarried). Salary commencing at £250 per annum.

**PORTSMOUTH PARIISH.**—Third Assistant Resident Medical Officer for St. Mary's Infirmary, Institution, and Children's Home. Salary £250 per annum.

**PORTSMOUTH ROYAL PORTSMOUTH HOSPITAL.**—Casualty Officer (male). Salary at the rate of £100 per annum.

**ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN,** Waterloo Road, S.E.1.—Non-Resident Casualty Officer for Out-patient Department. Salary £150 per annum.

**ST. JOHN'S HOSPITAL,** Lewisham, S.E.13.—Casualty Officer (male). Salary at the rate of £100 per annum for six months, rising to £125 per annum for three months.

**SEYMOUR'S HOSPITAL SOCIETY.**—Honorary Assistant Physician at the Hospital for Tropical Diseases, Endsleigh Gardens, W.C.

**SHEFFIELD ROYAL HOSPITAL.**—Resident Anaesthetist (male). Salary £80 per annum.

**SOMERSET COUNTY COUNCIL.**—(1) Assistant Tuberculosis Officer. (2) Tuberculosis Officer for Bath City. (3) Tuberculosis Officer for Western Area. Salary £600 per annum each.

**SWINNEY PARISH.**—Pathologist and Bacteriologist. Salary £450 per annum.

**STOCKTON AND THORNTON HOSPITAL,** Stockton-on-Tees.—Junior Resident Medical Officer (male). Salary £150 per annum.

**STROKE-ON-TRENT NORTH STAFFORDSHIRE ROYAL INFIRMARY.**—House-Surgeon. Salary £150 per annum.

**SWINDON BOROUGH.**—Assistant to Medical Officer of Health (male). Salary £600 per annum.

**TACON AND SOMERSET HOSPITAL.**—Senior and Junior Medical Officers. Salary £150 and £100 per annum respectively.

**WAREFIELD CITY.**—Assistant Medical Officer (woman). Salary £600 per annum.

**WEST END HOSPITAL FOR NERVOUS DISEASES.**—Senior House-Physician. Salary at the rate of £150 per annum.

**CERTIFYING FACTORY SURGEONS.**—The following vacancies have been announced: Kilwinning (Ayrshire), Kirkby (Lancashire), and applications to the Chief Inspector of Factories.

*This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.*

## DIARY OF SOCIETIES AND LECTURES.

**ROYAL SOCIETY OF MEDICINE.**  
*Social Evening.*—Mon., 8.30 p.m., Reception by the President and Lady Baily. 9.15 p.m., Address by Dr. Jane Walker: Saints, Medicine, and Surgery (with illustrations). Exhibits lent by the Wellcome Historical Medical Museum and by Miss Marie Leon will be on view. Music and light refreshments.

*General Meeting of Fellows.*—Tues., 5.30 p.m., Ballot for Election to Fellowship.

*Section of Pathology.*—Tues., 8.30 p.m., Professor J. McIntosh. Histology of Some Virus Infections of the Central Nervous System; Mr. A. Fleming: Influence of Temperature on the Agglutination of Bacteria; Dr. F. T. Ridley: A New Mixing Machine.

*Section of Dermatology.*—Thurs., 4 p.m., Cases.

*Section of Obstetrics.*—Fri., 8 p.m., Professor J. B. Cleland (University of Adelaide): Difficult Labour in a Pure-blooded Australian Aboriginal Woman; Mr. G. F. Gibberd: Results of Albuminuria during Pregnancy, with special reference to its relation to pregnancy kidney and death.

*Section of Medicine.*—Sat., 8 p.m., Discussion: Diathermy in the treatment of the various forms of high blood pressure, etc. To be opened by Professor Sidney Russ and Dr. T. F. Cotton, followed by Dr. Justina Wilson and Dr. Agnes Savill.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND,** Lincoln's Inn Fields, W.C.—Hunterian Lectures by Sir Arthur Keith. Mon., Wed., and Fri., 5 p.m. Factors connected in the Growth of the Human Body.

**ROYAL MICROSCOPICAL SOCIETY,** 20, Hanover Square, W.1.—Wed., 7.45 p.m., Presidential Address by Dr. James A. Murray: Staining and Structure.

**ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE,** 11, Chandos Street, W.1.—Thurs., 8.15 p.m., Surgeon Commander D. H. C. Owen, R.N.: Health Organization on H.M. Naval Base, Singapore, and its Results.

**CHILSEA CLINICAL SOCIETY,** St. George's Hospital.—Tues., 8.30 p.m., Clinical Meeting.

**HUNTERIAN SOCIETY,** The Mansion House, E.C.—Mon., 9 p.m., Hunterian Lecture by Dr. Howard Kelly (Baltimore): Rubbing and Reasoning.

**SOCIETY OF MEDICAL OFFICERS OF HEALTH,** 1, Upper Montague Street, W.G.1.—Fri., 5 p.m., Recent Advances in the Knowledge of Food. Speakers: Captain Walter Elliot, M.P., and Professor R. H. A. Plummer.

## POST-GRADUATE COURSES AND LECTURES.

**FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.**—Lecture at Medical Society, 11, Chandos Street, W.1. Mon., 5 p.m.: Acute Drunkenness. Royal Eye Hospital, St. George's Circus, S.E.1: Clinical Demonstration, Thurs., 3 p.m. The above are open to members of the medical profession without fee. **Bethlem Royal Hospital,** St. George's Fields, S.E.1: Course in Psychological Medicine: Lecture Demonstrations on Tues. and Sat., 11 a.m.; fee £1 1s. for series of eight. **Prince of Wales's General Hospital,** Tottenham, N.15: Course in Medicine, Surgery, and the Specialties: Demonstrations, Lectures, Ward Rounds, and Operations daily, 10.30 a.m. to 5.30 p.m.; fee £3 3s. for the week. **Children's Clinic,** and other hospitals: Post-graduate Course in Diseases of Children, occurring morning and some afternoons: second week.

**CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL,** Gray's Inn Road, W.C.1.—Mon., 1.30 p.m., Hearing Tests. Wed., 1.30 p.m., Examination of the Ear. Fri., 4 p.m., Demonstration of Museum Specimens.

**HOSPITAL FOR SICK CHILDREN,** Great Ormond Street, W.C.1.—Thurs., 4 p.m., Digestive Disturbances in Infancy and their Treatment.

**LONDON SCHOOL OF DERMATOLOGY,** St. John's Hospital, Leicester Square, W.C.2.—Tues., 5 p.m., Erythema Multiforme. Thurs., 5 p.m., Pathology Demonstration.

**NORTH-WEST LONDON POST-GRADUATE COLLEGE,** Prince of Wales's General Hospital, Tottenham, N.15.—Mon., 2.30 to 5 p.m., Medical, Surgical, and

**G.** Tues., 2.30 to 5 p.m., Medical, Clinics; Operations. Wed., 2.30 to 5 p.m., Operations. Thurs., 11.30 a.m., Surgical, and Ear, Nose, and Throat, 10.30 a.m., Throat, Nose, and Ear Medical, and Children's Diseases Clinics; Operations.

### NINETY-SIXTH ANNUAL MEETING, CARDIFF, JULY, 1928.

Patron: HIS MAJESTY THE KING.

President: SIR ROBERT W. PHILIP, M.D., LL.D., F.R.C.P.Ed., Consulting Physician, Royal Infirmary, Edinburgh.

President-Elect: SIR EWEN J. MACLEAN, M.D., F.R.C.P., Professor of Obstetrics, Welsh National School of Medicine.

Chairman of Representative Body: C. O. HAWTHORNE, M.D., F.R.C.P.

Chairman of Council: H. B. BRACKENBURY, M.R.C.S., L.R.C.P.

Treasurer: N. BISHOP HARMAN, M.B., F.R.C.S.

### PROVISIONAL PROGRAMME.

TOWER OF ST. JOHN'S CHURCH, CARDIFF.

THE incoming President, Sir EWEN MACLEAN, will deliver his address to the Association on Tuesday, July 24th, at 8 p.m.

The ANNUAL REPRESENTATIVE MEETING will begin on Friday, July 20th, at 10 a.m., and to continue on the three following week-days. The Representatives' Dinner will take place on Friday evening, July 20th, at 7.30.

The statutory ANNUAL GENERAL MEETING will be held on Tuesday, July 24th, at 2 p.m., and the adjourned general meeting at 8 p.m.

The Annual Dinner of the Association will take place on Thursday, July 26th.

The Conference of Honorary Secretaries will be held at 2.30 p.m. on Wednesday, July 25th, and the Secretaries' Dinner at 6.30 the same evening.

The official Religious Service will be held at St. John's Church, Cardiff, on Tuesday, July 24th, at 4.30 p.m.

The Annual Exhibition of surgical appliances, foods, drugs, and books will be open for inspection on Monday, July 23rd, from 2 till 6 p.m.; the formal opening by the President will take place on July 24th at 9.30 a.m. The exhibition will remain open on July 25th, 26th, and 27th from 9 a.m. till 6 p.m.

Saturday, July 28th, will be given up to excursions to places of interest in the neighbourhood.

### THE SECTIONS.

The Scientific Section will meet from 10 a.m. to 1 p.m. for papers and discussions on Wednesday, Thursday, and Friday, July 25th, 26th, and 27th.

The following Sections will meet on Three Days.

#### MEDICINE.

President: Sir THOMAS LEWIS, C.B.E., M.D., F.R.C.P., F.R.S. (Cardiff).

Vice-Presidents: IVOR J. DAVIES, M.D., F.R.C.P. (Cardiff); A. E. GOW, M.D., F.R.C.P. (London); A. FERGUS HEWAT, M.D., F.R.C.P.Ed. (Edinburgh); CYRIL LEWIS, M.D., C.M. (Cardiff); Professor T. GILLMAN MOORHEAD, M.D., F.R.C.P.I. (Dublin); H. LETHBRIDGE TIDY, M.D., F.R.C.P. (London).

Honorary Secretaries: ABEL EVANS, M.B., M.R.C.P., 36, Newport Road, Cardiff; ANTHONY FEILING, M.D., F.R.C.P., 52, Montagu Square, London, W.1.

#### SURGERY.

President: Professor A. W. SHEEN, C.B.E., M.S., F.R.C.S. (Cardiff).

Vice-Presidents: H. G. GRAHAM COOK, C.B.E., M.D., F.R.C.S. (Cardiff); C. H. FAGGE, M.S., F.R.C.S. (London); Professor ANDREW FULLERTON, C.B., C.M.G., M.Ch., F.R.C.S.I. (Belfast); J. W. GEARY GRANT, F.R.C.S. (Cardiff); WILLIAM MARTIN, M.B., C.M. (Cardiff); ALBERT J. WALTON, M.S., F.R.C.S. (London).

Honorary Secretaries: D. J. HARRIES, D.Sc., F.R.C.S., 106, Newport Road, Cardiff; R. ST. LEGER BROOKMAN, M.B., M.Ch., F.R.C.S., 79, Upper Hanover Street, Sheffield.

#### OBSTETRICS AND GYNAECOLOGY.

President: T. WATTS EDEN, M.D., F.R.C.P., F.R.C.S.Ed. (London).

Vice-Presidents: MARGARET M. BASDEN, M.D., F.R.C.S. (London); ARTHUR E. GILES, M.D., F.R.C.S.Ed. (London); Professor W. FLETCHER SHAW, M.D., Ch.B. (Manchester); Professor H. BECKWITH WHITEHOUSE, M.S., F.R.C.S. (Birmingham).

Honorary Secretaries: B. K. T. COLLINS, M.D., F.R.C.S.Ed., 12, Windsor Place, Cardiff; EVERARD WILLIAMS, M.D., 5, Wimpole Street, London, W.1.

# Annual Meeting, Cardiff: Officers of Sections.

[SUPPLEMENT TO THE  
BRITISH MEDICAL JOURNAL]

## The following Sections will meet on Two Days.

### **PATHOLOGY AND BACTERIOLOGY.**

*President:* Professor E. H. KETTLE, M.D., M.R.C.P. (London).  
*Vice-Presidents:* Professor JOHN CHICKSHANK, M.D. (Aberdeen);  
Sir THOMAS HOUSTON, O.B.E., M.D. (Belfast); W. PARRY MORGAN,  
M.D. (Cardiff); A. F. S. SLADDEN, M.D. (Swansea).  
*Honorary Secretaries:* J. B. DUGUID, M.D., Department of  
Pathology, Welsh National School of Medicine, The Parade,  
Cardiff; LAWRENCE P. GARROD, M.B., M.R.C.P., 68, Gloucester  
Terrace, Hyde Park, London, W.2.

### **MENTAL DISEASES AND NEUROLOGY.**

*President:* EDWIN GOODALL, C.B.E., M.D., F.R.C.P. (Cardiff).  
*Vice-Presidents:* E. D. ADRIAN, M.D., F.R.C.P., F.R.S. (Cam-  
bridge); G. H. R. GIBSON, D.S.O., M.D., F.R.C.P. (Edinburgh);  
BERNARD HART, M.D., F.R.C.P. (London); W. F. NELIS, M.D.  
(Cserleone, Mon.); N. R. PHILLIPS, M.D. (Aberavenny).  
*Honorary Secretaries:* EDWARD LEWIS, F.R.F.P.S., Drymma  
Hall, Skewen, nr. Neath, Glam.; W. R. REYNELL, M.D., M.R.C.P.,  
87, Harley Street, London, W.1.

### **ORTHOPAEDICS.**

*President:* Sir JOHN LYNN-THOMAS, K.B.E., C.B., C.M.G.  
F.R.C.S. (Llechryd).  
*Vice-Presidents:* A. ROCYN JONES, M.B., F.R.C.S. (London); J. J.  
MCINTOSH SHAW, M.C., M.D., F.R.C.S. (Edinburgh); S. ALWYN  
SMITH, D.S.O., O.B.E., M.D., F.R.C.S. (Cardiff); P. JENNER  
VERRALL, M.B., F.R.C.S. (London).  
*Honorary Secretaries:* J. BERRY HAYCRAFT, M.C., M.B., F.R.C.S.,  
31, Cathedral Road, Cardiff; ERIC IVAN LLOYD, M.B., F.R.C.S.,  
33, Wimpole Street, London, W.1.

### **DISEASES OF CHILDREN.**

*President:* ALFRED HOWELL, M.D., M.R.C.P. (Cardiff).  
*Vice-Presidents:* E. A. COCKAYNE, M.D., F.R.C.S. (London);  
HERBERT THOMAS EVANS, M.D., M.R.C.P. (Cardiff); CHARLES  
LEONARD ISAAC, M.B., F.R.C.S. (Swansea).  
*Honorary Secretaries:* DANIEL THOMAS DAVIES, M.D., M.R.C.P.,  
24, Park Place, Cardiff; HILDA N. STORRISGER, M.D., 11, Belmont  
House, Candover Street, London, W.1.

### **OPHTHALMOLOGY.**

*President:* F. P. S. CRESSWELL, M.B., F.R.C.S. (Cardiff).  
*Vice-Presidents:* HERBERT CAIGER, M.B., F.R.C.S. (Sheffield);  
L. V. CARGILL, F.R.C.S. (London); R. J. COULTER, M.B., F.R.C.S.I.  
(Newport, Mon.); F. GRIFFITH THOMAS, M.B., B.Ch. (Swansea).  
*Honorary Secretaries:* J. W. TUDOR THOMAS, M.B., F.R.C.S.,  
1, Park Grove, Cardiff; F. A. JULER, M.D., F.R.C.S., 14, Portland  
Place, London, W.1.

### **LARYNGOLOGY AND OTOTOLOGY.**

*President:* DONALD R. PATERSON, M.D., C.M., F.R.C.P. (Cardiff).  
*Vice-Presidents:* ALBAN EVANS, M.R.C.S., L.R.C.P. (Swansea);  
E. D. D. DAVIS, F.R.C.S. (London); ARCHIBALD MASON JONES,  
M.D., F.R.C.S. (Cardiff).  
*Honorary Secretaries:* A. A. PRICHARD, M.D., 14, Windsor Place,  
Cardiff; D. F. A. NEILSON, F.R.C.S., 40, Queen Anne Street,  
London, W.1.

### **TUBERCULOSIS.**

*President:* HUGH MORRISTON DAVIES, M.D., M.Ch., F.R.O.S.  
(Ruthio).  
*Vice-Presidents:* ALEXANDER BROWNLEE, M.D., F.R.C.S. (Ed-  
inburgh, nr. Cardiff); DAN ARTHUR POWELL, M.D. (Cardiff);  
CECIL WALL, M.D., F.R.C.P. (London).  
*Honorary Secretaries:* J. C. GILCHRIST, M.D., Tuberculosis  
Institution, Welsh National Memorial, Cardiff; J. C. HOYLE,  
M.B., B.S., 28, Malcolm Street, Cambridge.

### **RADIOLOGY AND PHYSIO-THERAPEUTICS.**

*President:* OWEN LEWELLIN RHYS, M.D. (Cardiff).  
*Vice-Presidents:* T. GARFIELD EVANS, M.D., D.M.R.E. (Cardiff);  
C. B. HEALD, C.B.E., M.D., M.R.C.P. (London); THOMAS MARLIN,  
M.D., D.M.R.E. (London).  
*Honorary Secretaries:* T. I. CANDY, M.B., B.Ch., 202, Stow Hill,  
Newport, Mon.; A. J. H. ILES, M.R.C.S., L.R.C.P., Shutterne  
House, Taunton.

## The following Sections will meet on One Day.

### **PREVENTIVE MEDICINE.**

*President:* EDWARD COLSTON WILLIAMS, M.D., F.R.C.S. (Ed-  
inburgh).  
*Vice-Presidents:* W. W. JAMESON, M.D., M.R.C.P. (London);  
DAVID LLEWELYN WILLIAMS, M.C., F.R.C.S. (Cardiff); C. A.  
BRISTOCKE, M.R.C.S. (Haverfordwest).  
*Honorary Secretaries:* H. W. CATTO, M.B., B.S., 198, Stow Hill,  
Newport, Mon.; D. C. KIRKUPPE, M.D. Town Hall, South  
Tottenham, London, N.15.

### **PUBLIC HEALTH.**

*President:* R. M. F. PICKEN, M.B., Ch.B. (Cardiff).  
*Vice-Presidents:* D. T. ROCYN JONES, C.B.E., M.B., C.M. (Ramney,  
nr. Cardiff); J. D. JENKINS, M.D. (Rhonda); S. G. MOORE, M.D.  
(Huddersfield).  
*Honorary Secretaries:* THOMAS EVANS, M.B., Public Health  
Department, Swansea; R. P. GARROW, M.D., Health Office,  
Saltergate, Chesterfield.

### **MEDICAL SOCIOLOGY.**

*President:* WILLIAM EVANS THOMAS, M.D., C.M. (Ystrad,  
Rhonda).  
*Vice-Presidents:* LETITIA DENNY FAIRFIELD, C.B.E., M.D.  
(London); EVAN LEWIS-LLOYD, M.R.C.S., L.R.C.P. (Towyn).  
*Honorary Secretary:* F. Y. PEARSON, M.R.C.S., L.R.C.P.,  
18, Crwys Road, Cardiff.

### **TROPICAL MEDICINE.**

*President:* PHILIP H. MANSON-BAHR, D.S.O., M.D., F.R.C.P.  
(London).  
*Vice-Presidents:* J. B. CHRISTOPHERSON, M.D., F.R.C.P., F.R.C.S.  
(London); Lieut.-Colonel A. G. MCKENDRICK, M.D., Ch.B.,  
F.R.C.S. (Ed.); I. M.S. (ret.) (Edinburgh).  
*Honorary Secretaries:* ERNEST HENRY PRICE, L.R.C.P.I., 153,  
Cathedral Road, Cardiff; H. MCCORMICK HANSHELL, D.S.C.,  
M.R.C.S., L.R.C.P., 35, Weymouth Street, London, W.1.

### **HISTORY OF MEDICINE.**

*President:* WALTER G. SPENCER, O.B.E., M.S., F.R.C.S. (London).  
*Vice-Presidents:* THOMAS WALLACE, M.D. (Cardiff); T. P. C.  
KIRKPATRICK, M.D., F.R.C.P.I. (Dublin); Professor J. A. NIXON,  
C.M.G., M.D., F.R.C.P. (Clifton); CHARLES SINGER, M.A., M.D.,  
F.R.C.P. (London).  
*Honorary Secretaries:* H. R. FREDERICK, M.B., Ch.B., 42, Victoria  
Road, Abertavon, Port Talbot, Glam.; KENNETH R. HAY, O.B.E.,  
M.B., 47, Hill Street, Berkeley Square, London, W.1.

### **THERAPEUTICS AND PHARMACOLOGY.**

*President:* W. LANGDON BROWN, M.D., F.R.C.P. (London).  
*Vice-Presidents:* Professor W. J. DILLING, M.B., Ch.B. (Liver-  
pool); PHILIP HAMILL, M.D., D.Sc., F.R.C.P. (London); W. H.  
MAXWELL TELLING, M.D., F.R.C.P. (Leeds).  
*Honorary Secretaries:* J. P. H. DAVIES, M.B., "Crummoor,"  
The Green, Llandaff, Cardiff; J. H. BURN, M.D., Pharmaceutical  
Society of Great Britain, Pharmacological Laboratory, 17, Blooms-  
bury Square, London, W.C.1.

### **DERMATOLOGY.**

*President:* Sir ROBERT BOLAM, M.D., LL.D., F.R.C.P. (Newcastle-  
on-Tyne).  
*Vice-Presidents:* JAMES BEATTY, M.D., M.R.C.P. (Cardiff);  
WILLIAM GRIFFITH, M.D., M.R.C.P. (London); HENRY SENIOR,  
M.D., M.R.C.P. (London).  
*Honorary Secretaries:* R. H. ENOCH, M.R.C.S., L.R.C.P., Royal  
Infirmary, Cardiff; J. E. M. WIGLEY, M.B., M.R.C.P., 132, Harley  
Street, London, W.1.

The Honorary Local General Secretary of the Annual  
Meeting is Dr. G. I. STRACHAN, 20, Windsor Place, Cardiff.

## British Medical Association.

### CURRENT NOTES.

#### British Medical Association House Extension.

THE work in connexion with the extension of the British  
Medical Association House, in accordance with resolutions  
of the Representative Body at Edinburgh, 1927, has now  
been commenced, and will be pressed forward as rapidly  
as possible. Two of the five houses for demolition have  
already disappeared, and the other three houses, Nos. 18,  
19, and 19A, Tavistock Square, have been vacated and  
handed over to the housebreakers. As a consequence, the  
National Association for the Prevention of Tuberculosis,  
whose offices were previously at No. 19, Tavistock Square,  
and the Federation of the Health Resorts of France, whose  
offices were in 19A, Tavistock Square, have been housed,  
temporarily, in No. 1, Gordon Square, London, W.C.1,  
to which address all communications from members to them  
should be sent. Preparations for the necessary excavations  
are well in hand, and it may be necessary in the com-  
paratively near future to close for traffic the private road  
leading into the Association's House from Tavistock Square,  
and even to close the garage. When the private road is  
closed, it will still be possible for cars to enter the Associa-  
tion's House by making a circuit from Tavistock Square  
through Tavistock Place and Marchmont Street and the  
southern side of Cartwright Gardens, entering through the  
driveway from Burton Street, between the Members'  
Common Room and the Library. Arrangements will, of  
course, be made for foot passengers to enter the Associa-  
tion's House from Tavistock Square during all stages of the  
building operations. It is proposed to publish in these  
columns, from time to time, particulars of the progress

which is made and details of the arrangements for lessening the inconveniences for members of the Association during the period of rebuilding.

#### Some Work of the Week.

During the week ending January 14th meetings were held by the Central Ethical Committee, the Maternity and Child Welfare Subcommittee, the Hospitals Committee, the Insurance Acts Committee, the Public Health Committee, and the Public Education in Health Committee. The main event of the week was, however, the conference on puerperal morbidity and mortality, which took place on January 11th. A full report of this will appear in an early issue of the SUPPLEMENT.

#### Development of Hospital Policy.

On January 11th the Hospitals Committee had before it an interim report from the subcommittee on the co-ordination of hospital provision, and framed answers to the questions on this matter suggested by the Ministry of Health for investigation by voluntary hospitals, health authorities, and boards of guardians. The principles laid down by the committee in these answers will come before the Council of the Association for ratification next month. The committee also had under consideration the amendment of paragraph 2 of the Hospital Policy, to provide that practitioners permitted to treat patients in private wards or nursing homes attached to hospitals shall conform to certain specified criteria, and much time was given to a review of the various contributory schemes, the conditions of which have been reported to the office. It is felt that the time has arrived to call another conference

of the medical staffs of voluntary hospitals to consider this and other developments, and the Hospitals Committee is recommending the Council accordingly. A suggestion that the Association should adopt a standard method of case-taking was rejected by the committee as impracticable.

#### Insurance Acts Committee.

The main business before the Insurance Acts Committee on January 12th was consideration of the draft alterations in the Regulations put forward by the Ministry of Health. The more important changes are those designed to put into force the disciplinary procedure agreed between the committee and the Ministry and approved by the conference. The draft Regulations were, generally speaking, approved as satisfactory, but several points were reserved for further discussion with the Ministry. Difficulties have been, and are likely to be, experienced in connexion with the Regulation embodying the revised procedure for change of doctor, and the committee approved the draft of a letter to local medical and panel committees dealing with this subject. The committee also approved a proposal by its chairman for an alteration of its constitution so as to provide for two extra representatives. It appointed a subcommittee to report on the compilation of a National Formulary, and considered the report of an informal conference between representatives of the committee, the Retail Pharmacists' Union, and the Ministry of Health on the compilation of a list of preparations which should not ordinarily be regarded as medicines for the purposes of the National Health Insurance Act. This last matter will be discussed further with the Retail Pharmacists' Union and the Ministry.

## An Address

ON

## THE MIDDLE YEARS.

DELIVERED TO THE ST. PANCRAS DIVISION OF THE BRITISH MEDICAL ASSOCIATION, JANUARY 10TH, 1928,

BY

SIR SQUIRE SPRIGGE, M.D.,  
EDITOR OF THE "LANCET."

WHEN your secretary gave me the flattering invitation to address you, and asked me to suggest a name for this discourse, I chose the title of "The Middle Years" without quite envisaging what the title might be taken to mean. I meant to talk mainly of the plight of Lister's immediate predecessors; but I came to see that their plight is, and should be, one that we are all of us in, and that the position of the men of that particular date was only a striking episode in the general story of medical progress. After choosing my title I found that Henry James had used the same title, not only in his later biography, but for one of his short stories, which had escaped my attention, and which, noting the complete absence of reference to it in the critical estimates of that much discussed author, I believe to have escaped the attention also of many. I read the story, and as it is illustrative to some extent of what I had proposed to say, as well as of a good deal else, a brief epitome of it may be used as a convenient text.

Henry James's narrative is concerned with an author who in his youth has splendid ideas, and in his middle age still has a plentiful supply of them, and also a perfected technique in which to express them, and a larger experience by the light of which to evaluate, support, or reject them. Those were the middle years for Henry James's hero, who at this point dies—conveniently for the moral which Henry James was pointing, but not for any convincing reason regarded medically. Henry James, so particular to conduct his stories with regard to probabilities, inside the strict limits which he laid down for himself, was not a sound observer of medical happenings.

The hero thus does not live into the third phase of activity—or the reverse—in an author's life, when the freshness of the ideas is lost, while the writing may have become mannered, and the philosophy stereotyped through

reiteration. The pathos of the story is that he dies in the flower of his talents—in the second stage, his middle years. His successes now give him the sense of progress; the good start is being justified, which tragedy prevents him from pursuing. But his life, so far as it was lived, is illustrative exactly of the growth of every branch of science, as well as of the life of every scientific man. In the accomplishments of an individual we have the same time-stages as occur in the development of a science, though it is noticeable that in our own calling the middle phase is often prolonged, so that we see veterans displaying no sign of lost freshness and no diminishing capacity either for receiving or imparting impressions. Remember Clifford Allbutt. For these fortunate few the third phase is never reached, but anyhow that phase is negligible, for it means that the worker is no longer old-fashioned, but obsolete as far as the world is concerned.

The analogy between the development of the individual and the development of the particular art or science concerned is complete if we remember that in neither case will progress cease, for the art or science will always be living and developing in association with that part of the work, done by the individual, which lives and develops when he has passed away. No term can be set to the progress of a doctor, for medical science will incorporate from the individual's activities his essential contributions to the wisdom of the world. No real worker dies. He dies as a man, but that part of his work which adds to the wisdom of the world lives, whether he is associated with it by name or no. Gentlemen, we may all be immortal. With every human activity, and, very exactly, with the science of medicine, we are always in the middle years, passing from the stage of unsupported imaginings into the stage when experience leads to the confirmation of the one thing and experiment to the rejection of another; and only in this way can orderly progress continue. The tentative and orderly progress of to-day will conduct us to the organized position of the future.

#### EARLY MEDICAL PROGRESS.

Orderly progress is a phrase much on our lips, but all who have realized something of the problems of heredity, either in the practice of medicine, in the laboratory, or in the profuse literature of the subject, know that the term "orderly progress" requires any amount of definition,

and to that literature I may refer you, as well as to your practical knowledge. It is sufficient to say that progress will at one time be in accordance with a pattern which can be perceived and anticipated, and at another time it may proceed by fits and starts, à bâtons rompus instead of with roulement, the drum-roll being replaced by the tattoo. It is by the stages of abrupt change that we become most aware of the orderly progress which is always going on, but which might otherwise escape our attention, so much do we take progress for granted; it is by the rapid transitions, as they occur, whether in professional life or in scientific accomplishment, that we become aware that we are always in the middle years—always using the knowledge of the past to make laws for the present, with the belief that the knowledge of the present, through which we may formulate new laws, will be revised for the formation of the laws of the future.

There is a great difference in the way in which new ideas are received, and when the term "old-fashioned" is employed we should be quite clear what we mean by it. For the last thirty or forty years in the obituary notices of a good many physicians and surgeons, all of whom were well known in their day, and some of whom have earned a secure place for ever in our annals, the phrases have occurred that with such a one "a type of the older school" or "one of the last of his day" has gone, or "a link with the past has been snapped"—somehow or other the impression is conveyed that the subject of the obituary notice was "old-fashioned." But, seeing the period of unlimited retrospect which such words as "the past" signify, we may ask what is meant by "old-fashioned"; and we shall find that those to whom the epithet is applied will usually be those whose most prominent work was done, and whose chief claims to remembrance were established, just before one of those fits or starts occurred in the progress of the science: just when the roll of the drum is replaced by the tattoo we become aware that we are in the middle years—we find with a shock that things are moving. The epithet "old-fashioned," as commonly used, seems to put a term to the period of antiquity, and to suggest that by comparison with the length of time which might have been brought into discussion, the range to be considered is brief. When the old-fashioned doctor is spoken of, while we imply that he is one whose methods are out of immediate date, we also imply that those methods have distinct affinity with the procedures of our time. No one would allude to Hippocrates as old-fashioned; and when, leaping not merely Roman civilization but the Dark Ages, we come to Harvey, we should still find the epithet inapplicable to Harvey. Neither of these men is of any time; each is an immortal. On the one hand, their technique bears no relation to modern methods; and, on the other hand, our technique is the result of discoveries and inventions often closely related to their work. And while we seem too far away from the era of the historic protagonists of medicine in our daily routine or our practical procedure to make it suitable to call them more or less old-fashioned, we should be more wrong to call them obsolete when we find constantly that cyclical recurrence of thought may render some of their observations pertinent to existing conditions. For this reason the exponents of early pathology should be approached with real respect, for in the light of new facts discovered and new experiences formulated the fancy of the past may become the fact of the present; the dogmatic statements of our predecessors we may discover to have been not necessarily incorrect because they were saddled in their day with explanations which have since proved to be erroneous. This position we shall see was noticeable after Harvey's discovery, when sound clinicians found that they had been furnished with logical grounds for what they had been doing already empirically.

The whole of what are called the Dark Ages present in most directions a period in which the middle years of human reasoning were marked by no universal revolution of thought. Until the Renaissance and the Reformation occurred the leaders of thought progressed along such traditional lines as had not been absolutely destroyed in the fading out of the Roman Empire; and, remembering that we are here thinking only in terms of medicine, we may

say that no surgeons or doctors during the whole period were called upon to revise seriously the teaching that they had received from Galen, founded upon that of Hippocrates, and not improved. The position which medicine in connexion with the study of natural science had reached in the time of the Ptolemys is comparable to its position in the sixteenth century—nothing between these dates occurred that could be regarded as progressively revolutionary, and, as a matter of fact, no marked changes even then occurred generally or rapidly. Many isolated observations were recorded which have since fallen into their proper places, but whose significance at the time went unrecognized. Along certain clinical paths Hippocrates was an up-to-date physician until Harvey's discovery, and when the Renaissance arrived, while additions were being made to our therapeutic knowledge, the scientific thinkers were actually less ready for the doctrine of the circulation of the blood than they would have been nearly two thousand years earlier in history. Harvey arrived with his grand demonstration of the mystery of the circulation of the blood in 1628, and had hard work to convince his own colleagues that he was right; he might have found it easier to discuss the mechanism of the circulation with the great anatomists of Alexandria than with any of the contemporary mystics. In what are called the Middle Ages of the world—that is, in mediæval days—scientific progress was in many directions imperceptible.

It may be noted that the colloquial use of the term "Middle Ages," in contradistinction to Dark Ages, as referring to the fourteenth, fifteenth, and sixteenth centuries exactly bears out what has been already suggested—namely, that it is only when a big revolution of thought occurs that the fact becomes obvious that we are living in the middle years of a progressive state. Historians regard the Middle Ages, roughly speaking, as covering the thousand years between the fall of the last Emperor of the West and the fall of Constantinople. But in common speech we have taken to applying the term Middle Ages to the last quarter, or less, of that period of a thousand years. The reason, of course, is that it was during this closing epoch that revolution of thought made so dramatic a show, the period when the thinking world became aware that it was in its middle years. The belief that nothing happened at all worth counting in the evolution of society until the humanism of the Renaissance was easy; modern research has shown that this view is superficial and that the progress of European society has been continuous, although not uniform. During that thousand years between the disappearance of ancient learning with the collapse of the Roman Empire and its recovery or rediscovery as a basis upon which the social history of the world could develop, the mental activities of man were not wholly absorbed by the struggles between barbarian races, nor later were they wholly under the spell of feudal rule or ecclesiastical authority. In science, however, compared with political advances, but little did happen throughout the whole period known to historians as the Middle Ages, and it is a fair generalization to say, using the phrase to cover the whole thousand years, that mediæval thought was generally inconsequent and uncritical in scientific matters. The real middle years of medicine as a whole (when the learning of the past was being correlated with the work of the present to form the developments of the future) occurred at the end of that thousand years. Until then no marked difference could have been perceived, either by their colleagues or by the public, between the tenets of one physician and those of his immediate predecessor or his immediate successor. In a local school of thought a fashion might prevail which would for a time give an appearance of old fashion to those who did not fall into line; but there was no disturbance of fundamentals, and until this happens those who are just behind their immediate date have little to warn them of their plight, nor is their slowness much detected by others. The progress that has been going on in their science has been gradually and largely concealed, and the former leaders can remain in close intellectual touch with the developments due to the work of their followers, for this work has been the logical outcome of their own teaching, which was accepted in the main. Every time that revision is called for something is

superseded; but the more that such supersessions take place gradually, the more will it seem that a pause has occurred in the pursuit of knowledge; and we are only brought to a sense that the pause is imaginary by some dramatic and fundamental discovery—something which arises *de novo*, or is a late fructification of ideas sown earlier and arriving at maturity perhaps by accident, just as accident may have checked earlier development.

It has often been pointed out that between discovery of the burning glass and the arrival of the microscope about two thousand years elapsed; if Archimedes had discovered the microscope the history of the world would have been altered.

#### THE RECEPTION OF HARVEY'S DISCOVERY.

Now the history of medicine was definitely altered by Harvey's discovery, incidentally without the aid of the microscope, for he had to assume the existence of the capillary connexion between the arteries and the veins which was demonstrated a few years later by Malpighi. Harvey's discovery was made and promulgated in a faultless way. Before he was ready with the exact demonstration he taught publicly in accordance with his theories, and although so radical a rearrangement of all physiology was not, and was not likely to be, accepted by all and immediately, he had on his side throughout some of the greatest thinkers. Here was no suspension of one technique for another, no isolated improvement in therapeutics, but a complete revolution, rendering immediately those who did not practise medicine in accordance with the new physiology not merely old-fashioned (in the sense that they were disregarding some fresh reading of an observed phenomenon or were neglecting the use of some more effective remedial measure), but obsolete from the point of view of scientific medicine. We may see how the discovery was received by observing what anticipations ushered it in, and what results immediately followed. A convenient way to do this will be to look at the medical science of two acknowledged heroes of medicine whose dates cover the period antecedent to and just posterior to Harvey's discovery. Harvey was born in 1578 and died in 1667, and announced his discovery of the circulation of the blood in the treatise *De Motu Cordis et Sanguinis* in the year 1628. Linaere, the founder of the Royal College of Physicians, was born in 1460 and died in 1524—that is to say, fifty years before Harvey was born, while his fame may be said to have reached its apex about one hundred years before the *De Motu* was published. Sydenham was born in 1624—that is to say, exactly a hundred years after Linaere's death. He lived till 1689, and his active career covered the whole of the period of Harvey's physiological work.

Linaere was more of a scholar than a scientist, although he appears to have been considered a great clinician. He was certainly a fine classical scholar, but his complete reliance on tradition is shown by the fame which he obtained for his translation of the works of Galen into Latin. This translation was acclaimed by Erasmus as being a better version than Galen's original Greek work, and there seems no reason to suppose that Linaere considered that medicine demanded more from him than a translation into the Roman dialect of the writings of the Roman author who preferred to use the fashionable Greek tongue. Linaere certainly performed a great literary exploit, for it is seldom indeed that a translation is able to do real justice to an original. He also founded the Royal College of Physicians of London, and in so doing had a fine conception for the organization and elevation of the medical profession. He was full of the dignity and virtue of his calling; but those who have studied his work do not seem to have recorded to his credit any mission to change the fundamentals of science as it had come down from Hippocrates through Galen. He had no knowledge that he was living in changing times, and medicine generally followed his official lead. At almost exactly the same time an infinitely greater person than Linaere, Rabelais, was manifesting a similar content with existing knowledge. Rabelais was familiar with the scientific knowledge of his epoch, and in 1537 delivered his medical lectures at Montpellier upon the works of Hippocrates. If there had been anything

subversive of the early Greek doctrines contemplated by medicine Rabelais would have known it, and would have exerted in publishing it.

And if Rabelais and Linaere had no prophetic glimpses, we need not be much surprised that the doctors of Harvey's day, save those in his immediate contact, were equally unprepared. Sydenham, Harvey's contemporary, seems not to have recognized the significance of Harvey's work. This is curious in a man who recorded his disapprobation of those who disliked all that is new and who reprobated the promulgation of doctrines to the public which they had not previously heard of. But Sydenham may have been in no mental contact with Harvey. He appears to have been no student of anatomy, but a great clinical physician; thus he was able to act empirically upon lines which the new learning would have justified. Possibly he, like Shakespeare—or so it is often alleged—may have had some sort of knowledge that the physics of the circulation were soon to be made the subject of some drastic discovery, but the arguments for Shakespeare's prevision seem untrustworthy. Shakespeare died the very week that Harvey made his announcement, and the passage in *Coriolanus*, wherein he is held to have foreshadowed the circulation of the blood, is based upon a fable in Aesop. And so far from believing that the arteries contained blood, he speaks of them as containing spirits. Shakespeare had some unexpected anatomical knowledge—for example, his references to the pia mater—and this he may have gained from seeing the illustrations to Helkiah Crooke's *Anatomy*, which was printed, according to Sir Benjamin Ward Richardson, next door to the Globe Theatre; but Crooke's work brings together all known anatomy of the arterial and venous system to the latest point before Harvey's discovery, to which no allusion is made. Nothing that Shakespeare wrote can be strained to mean that he had an acquaintance with Harvey's preliminary studies; and Sydenham was in similar condition, and basked in the title of the English Hippocrates.

How did the exponents of medicine take the unprepared and therefore unexpected revolution in their science? They responded well to the shock which they had received, considering that they were not well adapted to bear it. It is true that the discovery produced this situation among practitioners of medicine—it compelled those who did not accept the truth to remain dependent upon empiricism instead of upon reasoning, but—an important reservation—it did not deprive them of their valuable knowledge. The leaders of medicine after Harvey's discovery did not in any serious way challenge it, but they adapted their clinical methods in accordance with the new teaching, and, to the enormous credit of the old fathers and ancient prophets, no great alterations were needed in day-by-day routine. In a large measure the medical men succeeding Harvey found themselves supplied with reasons for what they had previously been doing upon traditional grounds. This, of course, is a very general statement and becomes less and less accurate as the reference is to periods further and further away from 1628. They showed that the medical man who cannot immediately get into intimate touch with modern developments does not lose his philosophic insight into his calling, where he is the heir to a long lineage of experience and research; for he knows that many truths, when enunciated, have escaped attention or been buried under irrelevancies, and he can console himself with the assurance that the essentials, to which he holds tenaciously, are the things that count for the good of mankind.

When, in the drawn-out story of intellectual progress, there comes a discovery which revolutionizes contemporary thought, the whole situation is changed. A new essential—not a new piece of technique—is added, and, as far as the profession of medicine is concerned, all those who are unable to carry on their work in accordance with the discovery, and in association with its relations to their theory and technique, will become old-fashioned. But those who find themselves in this plight will be obsolete in such measure as previous equipment enables them, or does not enable them, to adapt the teachings of the old essentials to the differences entailed by the new learning. The medical men of the seventeenth century gave a good

account of themselves when they became suddenly aware that they stood in the middle years—between the precepts of the past and the learning of the future. It was a large gap that was suddenly bridged for them—in time a thousand years, and in biology the whole mechanism. They were asked to accept the new doctrines unprepared by any warnings; there had been no general advance in physics to help in the comprehension of the new physiology; and there was no medical or scientific literature having any circulation. They did well.

#### THE RECEPTION OF LISTER'S WORK.
